2 [*Example 1*: A function that generates random numbers can model `invocable`, since the `invoke` function call expression is not required to be equality-preserving (18.2). — *end example*]

18.7.3 Concept `regular_invocable` [concept.regularinvocable]

```
template<class F, class... Args>
  concept regular_invocable = invocable<F, Args...>;
```

1 The `invoke` function call expression shall be equality-preserving (18.2) and shall not modify the function object or the arguments.

[*Note 1*: This requirement supersedes the "not required to be equality-preserving" comment in the definition of `invocable`. — *end note*]

2 [*Example 1*: A random number generator does not model `regular_invocable`. — *end example*]

3 [*Note 2*: The distinction between `invocable` and `regular_invocable` is purely semantic. — *end note*]

18.7.4 Concept `predicate` [concept.predicate]

```
template<class F, class... Args>
  concept predicate =
    regular_invocable<F, Args...> && boolean-testable<invoke_result_t<F, Args...>>;
```

18.7.5 Concept `relation` [concept.relation]

```
template<class R, class T, class U>
  concept relation =
    predicate<R, T, T> && predicate<R, U, U> &&
    predicate<R, T, U> && predicate<R, U, T>;
```

18.7.6 Concept `equivalence_relation` [concept.equiv]

```
template<class R, class T, class U>
  concept equivalence_relation = relation<R, T, U>;
```

1 A `relation` models `equivalence_relation` only if it imposes an equivalence relation on its arguments.

18.7.7 Concept `strict_weak_order` [concept.strictweakorder]

```
template<class R, class T, class U>
  concept strict_weak_order = relation<R, T, U>;
```

1 A `relation` models `strict_weak_order` only if it imposes a *strict weak ordering* on its arguments.

2 The term *strict* refers to the requirement of an irreflexive relation (`!comp(x, x)` for all `x`), and the term *weak* to requirements that are not as strong as those for a total ordering, but stronger than those for a partial ordering. If we define `equiv(a, b)` as `!comp(a, b) && !comp(b, a)`, then the requirements are that `comp` and `equiv` both be transitive relations:

(2.1) — `comp(a, b) && comp(b, c)` implies `comp(a, c)`

(2.2) — `equiv(a, b) && equiv(b, c)` implies `equiv(a, c)`

3 [*Note 1*: Under these conditions, it can be shown that

(3.1) — `equiv` is an equivalence relation,

(3.2) — `comp` induces a well-defined relation on the equivalence classes determined by `equiv`, and

(3.3) — the induced relation is a strict total ordering.

— *end note*]

19 Diagnostics library [diagnostics]

19.1 General [diagnostics.general]

1 This Clause describes components that C++ programs may use to detect and report error conditions.

2 The following subclauses describe components for reporting several kinds of exceptional conditions, documenting program assertions, obtaining stacktraces, and a global variable for error number codes, as summarized in Table 49.

Table 49 — Diagnostics library summary [tab:diagnostics.summary]

	Subclause	Header
19.2	Exception classes	`<stdexcept>`
19.3	Assertions	`<cassert>`
19.4	Error numbers	`<cerrno>`
19.5	System error support	`<system_error>`
19.6	Stacktrace	`<stacktrace>`
19.7	Debugging	`<debugging>`

19.2 Exception classes [std.exceptions]

19.2.1 General [std.exceptions.general]

1 The C++ standard library provides classes to be used to report certain errors (16.4.6.14) in C++ programs. In the error model reflected in these classes, errors are divided into two broad categories: *logic* errors and *runtime* errors.

2 The distinguishing characteristic of logic errors is that they are due to errors in the internal logic of the program. In theory, they are preventable.

3 By contrast, runtime errors are due to events beyond the scope of the program. They cannot be easily predicted in advance. The header `<stdexcept>` defines several types of predefined exceptions for reporting errors in a C++ program. These exceptions are related by inheritance.

19.2.2 Header `<stdexcept>` synopsis [stdexcept.syn]

```
namespace std {
  class logic_error;
    class domain_error;
    class invalid_argument;
    class length_error;
    class out_of_range;
  class runtime_error;
    class range_error;
    class overflow_error;
    class underflow_error;
}
```

19.2.3 Class `logic_error` [logic.error]

```
namespace std {
  class logic_error : public exception {
  public:
    constexpr explicit logic_error(const string& what_arg);
    constexpr explicit logic_error(const char* what_arg);
  };
}
```

1 The class `logic_error` defines the type of objects thrown as exceptions to report errors presumably detectable before the program executes, such as violations of logical preconditions or class invariants.

```
constexpr logic_error(const string& what_arg);
```

2 *Postconditions*: `strcmp(what(), what_arg.c_str()) == 0`.

```
constexpr logic_error(const char* what_arg);
```

3 *Postconditions*: `strcmp(what(), what_arg) == 0`.

19.2.4 Class `domain_error` [domain.error]

```
namespace std {
  class domain_error : public logic_error {
  public:
    constexpr explicit domain_error(const string& what_arg);
    constexpr explicit domain_error(const char* what_arg);
  };
}
```

1 The class `domain_error` defines the type of objects thrown as exceptions by the implementation to report domain errors.

```
constexpr domain_error(const string& what_arg);
```

2 *Postconditions*: `strcmp(what(), what_arg.c_str()) == 0`.

```
constexpr domain_error(const char* what_arg);
```

3 *Postconditions*: `strcmp(what(), what_arg) == 0`.

19.2.5 Class `invalid_argument` [invalid.argument]

```
namespace std {
  class invalid_argument : public logic_error {
  public:
    constexpr explicit invalid_argument(const string& what_arg);
    constexpr explicit invalid_argument(const char* what_arg);
  };
}
```

1 The class `invalid_argument` defines the type of objects thrown as exceptions to report an invalid argument.

```
constexpr invalid_argument(const string& what_arg);
```

2 *Postconditions*: `strcmp(what(), what_arg.c_str()) == 0`.

```
constexpr invalid_argument(const char* what_arg);
```

3 *Postconditions*: `strcmp(what(), what_arg) == 0`.

19.2.6 Class `length_error` [length.error]

```
namespace std {
  class length_error : public logic_error {
  public:
    constexpr explicit length_error(const string& what_arg);
    constexpr explicit length_error(const char* what_arg);
  };
}
```

1 The class `length_error` defines the type of objects thrown as exceptions to report an attempt to produce an object whose length exceeds its maximum allowable size.

```
constexpr length_error(const string& what_arg);
```

2 *Postconditions*: `strcmp(what(), what_arg.c_str()) == 0`.

```
constexpr length_error(const char* what_arg);
```

3 *Postconditions*: `strcmp(what(), what_arg) == 0`.

19.2.7 Class `out_of_range` [out.of.range]

```
namespace std {
  class out_of_range : public logic_error {
  public:
    constexpr explicit out_of_range(const string& what_arg);
    constexpr explicit out_of_range(const char* what_arg);
  };
}
```

1 The class `out_of_range` defines the type of objects thrown as exceptions to report an argument value not in its expected range.

```
constexpr out_of_range(const string& what_arg);
```

2 *Postconditions*: `strcmp(what(), what_arg.c_str()) == 0`.

```
constexpr out_of_range(const char* what_arg);
```

3 *Postconditions*: `strcmp(what(), what_arg) == 0`.

19.2.8 Class `runtime_error` [runtime.error]

```
namespace std {
  class runtime_error : public exception {
  public:
    constexpr explicit runtime_error(const string& what_arg);
    constexpr explicit runtime_error(const char* what_arg);
  };
}
```

1 The class `runtime_error` defines the type of objects thrown as exceptions to report errors presumably detectable only when the program executes.

```
constexpr runtime_error(const string& what_arg);
```

2 *Postconditions*: `strcmp(what(), what_arg.c_str()) == 0`.

```
constexpr runtime_error(const char* what_arg);
```

3 *Postconditions*: `strcmp(what(), what_arg) == 0`.

19.2.9 Class `range_error` [range.error]

```
namespace std {
  class range_error : public runtime_error {
  public:
    constexpr explicit range_error(const string& what_arg);
    constexpr explicit range_error(const char* what_arg);
  };
}
```

1 The class `range_error` defines the type of objects thrown as exceptions to report range errors in internal computations.

```
constexpr range_error(const string& what_arg);
```

2 *Postconditions*: `strcmp(what(), what_arg.c_str()) == 0`.

```
constexpr range_error(const char* what_arg);
```

3 *Postconditions*: `strcmp(what(), what_arg) == 0`.

19.2.10 Class `overflow_error` [overflow.error]

```
namespace std {
  class overflow_error : public runtime_error {
  public:
    constexpr explicit overflow_error(const string& what_arg);
    constexpr explicit overflow_error(const char* what_arg);
  };
}
```

1 The class `overflow_error` defines the type of objects thrown as exceptions to report an arithmetic overflow error.

```
constexpr overflow_error(const string& what_arg);
```

2 *Postconditions*: `strcmp(what(), what_arg.c_str()) == 0`.

```
constexpr overflow_error(const char* what_arg);
```

3 *Postconditions*: `strcmp(what(), what_arg) == 0`.

19.2.11 Class `underflow_error` [underflow.error]

```
namespace std {
  class underflow_error : public runtime_error {
  public:
    constexpr explicit underflow_error(const string& what_arg);
    constexpr explicit underflow_error(const char* what_arg);
  };
}
```

1 The class `underflow_error` defines the type of objects thrown as exceptions to report an arithmetic underflow error.

```
constexpr underflow_error(const string& what_arg);
```

2 *Postconditions*: `strcmp(what(), what_arg.c_str()) == 0`.

```
constexpr underflow_error(const char* what_arg);
```

3 *Postconditions*: `strcmp(what(), what_arg) == 0`.

19.3 Assertions [assertions]

19.3.1 General [assertions.general]

1 The header `<cassert>` provides a macro for documenting C++ program assertions and a mechanism for disabling the assertion checks through defining the macro `NDEBUG`.

19.3.2 Header `<cassert>` synopsis [cassert.syn]

```
#define assert(...) see below
```

19.3.3 The `assert` macro [assertions.assert]

1 If `NDEBUG` is defined as a macro name at the point in the source file where `<cassert>` is included, the `assert` macro is defined as

```
#define assert(...) ((void)0)
```

2 Otherwise, the `assert` macro puts a diagnostic test into programs; it expands to an expression of type `void` which has the following effects:

(2.1) — `__VA_ARGS__` is evaluated and contextually converted to `bool`.

(2.2) — If the evaluation yields `true` there are no further effects.

(2.3) — Otherwise, the `assert` macro's expression creates a diagnostic on the standard error stream (ISO/IEC 9899:2024, 7.23.3) in an implementation-defined format and calls `abort()`. The diagnostic contains `#__VA_ARGS__` and information on the name of the source file, the source line number, and the name of the enclosing function (such as provided by `source_location::current()`).

3 If `__VA_ARGS__` does not expand to a well-formed *assignment-expression*, the program is ill-formed. If such an *assignment-expression* is ill-formed when treated as an unevaluated operand (7.6.2.4, 7.6.17), the program is ill-formed, no diagnostic required.

4 The macro `assert` is redefined according to the current state of `NDEBUG` each time that `<cassert>` is included.

5 An expression `assert(E)` is a constant subexpression (3.15), if

(5.1) — `NDEBUG` is defined at the point where `assert` is last defined or redefined, or

(5.2) — `E` contextually converted to `bool` (7.3) is a constant subexpression that evaluates to the value `true`.

19.4 Error numbers [errno]

19.4.1 General [errno.general]

1 The contents of the header `<cerrno>` are the same as the POSIX header `<errno.h>`, except that `errno` shall be defined as a macro.

[*Note 1*: The intent is to remain in close alignment with the POSIX standard. — *end note*]

A separate `errno` value is provided for each thread.

19.4.2 Header <cerrno> synopsis [cerrno.syn]

```
#define errno see below

#define E2BIG see below                          // freestanding

#define EXDEV see below                                        // freestanding
```

1 The meaning of the macros in this header is defined by the POSIX standard.

See also: ISO/IEC 9899:2024, 7.5

19.5 System error support [syserr]

19.5.1 General [syserr.general]

1 Subclause 19.5 describes components that the standard library and C++ programs may use to report error conditions originating from the operating system or other low-level application program interfaces.

2 Components described in 19.5 do not change the value of `errno` (19.4).

Recommended practice: Implementations should leave the error states provided by other libraries unchanged.

19.5.2 Header <system_error> synopsis [system.error.syn]

```
#include <compare>              // see 17.12.1

```
};

template<> struct is_error_condition_enum<errc> : true_type {};

// 19.5.4.5, non-member functions
error_code make_error_code(errc e) noexcept;

template<class charT, class traits>
  basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const error_code& ec);

// 19.5.5.5, non-member functions
error_condition make_error_condition(errc e) noexcept;

// 19.5.6, comparison operator functions
bool operator==(const error_code& lhs, const error_code& rhs) noexcept;
bool operator==(const error_code& lhs, const error_condition& rhs) noexcept;
bool operator==(const error_condition& lhs, const error_condition& rhs) noexcept;
strong_ordering operator<=>(const error_code& lhs, const error_code& rhs) noexcept;
strong_ordering operator<=>(const error_condition& lhs, const error_condition& rhs) noexcept;

// 19.5.7, hash support
template<class T> struct hash;
template<> struct hash<error_code>;
template<> struct hash<error_condition>;

// 19.5, system error support
template<class T>
  constexpr bool is_error_code_enum_v = is_error_code_enum<T>::value;
template<class T>
  constexpr bool is_error_condition_enum_v = is_error_condition_enum<T>::value;
}
```

1 The value of each `enum errc` enumerator is the same as the value of the `<cerrno>` macro shown in the above synopsis. Whether or not the `<system_error>` implementation exposes the `<cerrno>` macros is unspecified.

2 The `is_error_code_enum` and `is_error_condition_enum` templates may be specialized for program-defined types to indicate that such types are eligible for `class error_code` and `class error_condition` implicit conversions, respectively.

19.5.3 Class `error_category` [syserr.errcat]

19.5.3.1 Overview [syserr.errcat.overview]

1 The class `error_category` serves as a base class for types used to identify the source and encoding of a particular category of error code. Classes may be derived from `error_category` to support categories of errors in addition to those defined in this document. Such classes shall behave as specified in subclause 19.5.3.

[*Note 1*: `error_category` objects are passed by reference, and two such objects are equal if they have the same address. If there is more than a single object of a custom `error_category` type, such equality comparisons can evaluate to `false` even for objects holding the same value. — *end note*]

```
namespace std {
  class error_category {
  public:
    constexpr error_category() noexcept;
    virtual ~error_category();
    error_category(const error_category&) = delete;
    error_category& operator=(const error_category&) = delete;
    virtual const char* name() const noexcept = 0;
    virtual error_condition default_error_condition(int ev) const noexcept;
    virtual bool equivalent(int code, const error_condition& condition) const noexcept;
    virtual bool equivalent(const error_code& code, int condition) const noexcept;
    virtual string message(int ev) const = 0;

    bool operator==(const error_category& rhs) const noexcept;
    strong_ordering operator<=>(const error_category& rhs) const noexcept;
```

```
  };

  const error_category& generic_category() noexcept;
  const error_category& system_category() noexcept;
}
```

19.5.3.2 Virtual members [syserr.errcat.virtuals]

```
virtual const char* name() const noexcept = 0;
```

1 *Returns*: A string naming the error category.

```
virtual error_condition default_error_condition(int ev) const noexcept;
```

2 *Returns*: `error_condition(ev, *this)`.

```
virtual bool equivalent(int code, const error_condition& condition) const noexcept;
```

3 *Returns*: `default_error_condition(code) == condition`.

```
virtual bool equivalent(const error_code& code, int condition) const noexcept;
```

4 *Returns*: `*this == code.category() && code.value() == condition`.

```
virtual string message(int ev) const = 0;
```

5 *Returns*: A string that describes the error condition denoted by `ev`.

19.5.3.3 Non-virtual members [syserr.errcat.nonvirtuals]

```
bool operator==(const error_category& rhs) const noexcept;
```

1 *Returns*: `this == &rhs`.

```
strong_ordering operator<=>(const error_category& rhs) const noexcept;
```

2 *Returns*: `compare_three_way()(this, &rhs)`.

[*Note 1*: `compare_three_way` (22.10.8.8) provides a total ordering for pointers. — *end note*]

19.5.3.4 Program-defined classes derived from `error_category` [syserr.errcat.derived]

```
virtual const char* name() const noexcept = 0;
```

1 *Returns*: A string naming the error category.

```
virtual error_condition default_error_condition(int ev) const noexcept;
```

2 *Returns*: An object of type `error_condition` that corresponds to `ev`.

```
virtual bool equivalent(int code, const error_condition& condition) const noexcept;
```

3 *Returns*: `true` if, for the category of error represented by `*this`, `code` is considered equivalent to `condition`; otherwise, `false`.

```
virtual bool equivalent(const error_code& code, int condition) const noexcept;
```

4 *Returns*: `true` if, for the category of error represented by `*this`, `code` is considered equivalent to `condition`; otherwise, `false`.

19.5.3.5 Error category objects [syserr.errcat.objects]

```
const error_category& generic_category() noexcept;
```

1 *Returns*: A reference to an object of a type derived from class `error_category`. All calls to this function shall return references to the same object.

2 *Remarks*: The object's `default_error_condition` and `equivalent` virtual functions shall behave as specified for the class `error_category`. The object's `name` virtual function shall return a pointer to the string `"generic"`.

```
const error_category& system_category() noexcept;
```

3 *Returns*: A reference to an object of a type derived from class `error_category`. All calls to this function shall return references to the same object.

4 *Remarks*: The object's `equivalent` virtual functions shall behave as specified for class `error_category`. The object's `name` virtual function shall return a pointer to the string `"system"`. The object's `default_error_condition` virtual function shall behave as follows:

If the argument `ev` is equal to 0, the function returns `error_condition(0, generic_category())`. Otherwise, if `ev` corresponds to a POSIX `errno` value `pxv`, the function returns `error_condition(pxv, generic_category())`. Otherwise, the function returns `error_condition(ev, system_category())`. What constitutes correspondence for any given operating system is unspecified.

[*Note 1*: The number of potential system error codes is large and unbounded, and some might not correspond to any POSIX `errno` value. Thus implementations are given latitude in determining correspondence. — *end note*]

19.5.4 Class `error_code` [syserr.errcode]

19.5.4.1 Overview [syserr.errcode.overview]

1 The class `error_code` describes an object used to hold error code values, such as those originating from the operating system or other low-level application program interfaces.

[*Note 1*: Class `error_code` is an adjunct to error reporting by exception. — *end note*]

```
namespace std {
  class error_code {
  public:
    // 19.5.4.2, constructors
    error_code() noexcept;
    error_code(int val, const error_category& cat) noexcept;
    template<class ErrorCodeEnum>
      error_code(ErrorCodeEnum e) noexcept;

    // 19.5.4.3, modifiers
    void assign(int val, const error_category& cat) noexcept;
    template<class ErrorCodeEnum>
      error_code& operator=(ErrorCodeEnum e) noexcept;
    void clear() noexcept;

    // 19.5.4.4, observers
    int value() const noexcept;
    const error_category& category() const noexcept;
    error_condition default_error_condition() const noexcept;
    string message() const;
    explicit operator bool() const noexcept;

  private:
    int val_;                       // exposition only
    const error_category* cat_; // exposition only
  };

  // 19.5.4.5, non-member functions
  error_code make_error_code(errc e) noexcept;

  template<class charT, class traits>
    basic_ostream<charT, traits>&
      operator<<(basic_ostream<charT, traits>& os, const error_code& ec);
}
```

19.5.4.2 Constructors [syserr.errcode.constructors]

```
error_code() noexcept;
```

1 *Effects*: Initializes *val_* with 0 and *cat_* with `&system_category()`.

```
error_code(int val, const error_category& cat) noexcept;
```

2 *Effects*: Initializes *val_* with `val` and *cat_* with `&cat`.

```
template<class ErrorCodeEnum>
  error_code(ErrorCodeEnum e) noexcept;
```

3 *Constraints*: `is_error_code_enum_v<ErrorCodeEnum>` is `true`.

4 *Effects*: Equivalent to:

```
error_code ec = make_error_code(e);
assign(ec.value(), ec.category());
```

19.5.4.3 Modifiers [syserr.errcode.modifiers]

```
void assign(int val, const error_category& cat) noexcept;
```

1 *Postconditions*: *val_* `==` `val` and *cat_* `==` `&cat`.

```
template<class ErrorCodeEnum>
  error_code& operator=(ErrorCodeEnum e) noexcept;
```

2 *Constraints*: `is_error_code_enum_v<ErrorCodeEnum>` is `true`.

3 *Effects*: Equivalent to:

```
error_code ec = make_error_code(e);
assign(ec.value(), ec.category());
```

4 *Returns*: `*this`.

```
void clear() noexcept;
```

5 *Postconditions*: `value() == 0` and `category() == system_category()`.

19.5.4.4 Observers [syserr.errcode.observers]

```
int value() const noexcept;
```

1 *Returns*: *val_*.

```
const error_category& category() const noexcept;
```

2 *Returns*: **cat_*.

```
error_condition default_error_condition() const noexcept;
```

3 *Returns*: `category().default_error_condition(value())`.

```
string message() const;
```

4 *Returns*: `category().message(value())`.

```
explicit operator bool() const noexcept;
```

5 *Returns*: `value() != 0`.

19.5.4.5 Non-member functions [syserr.errcode.nonmembers]

```
error_code make_error_code(errc e) noexcept;
```

1 *Returns*: `error_code(static_cast<int>(e), generic_category())`.

```
template<class charT, class traits>
  basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const error_code& ec);
```

2 *Effects*: Equivalent to: `return os << ec.category().name() << ':' << ec.value();`

19.5.5 Class `error_condition` [syserr.errcondition]

19.5.5.1 Overview [syserr.errcondition.overview]

1 The class `error_condition` describes an object used to hold values identifying error conditions.

[*Note 1*: `error_condition` values are portable abstractions, while `error_code` values (19.5.4) are implementation specific. — *end note*]

```
namespace std {
  class error_condition {
  public:
    // 19.5.5.2, constructors
    error_condition() noexcept;
    error_condition(int val, const error_category& cat) noexcept;
    template<class ErrorConditionEnum>
      error_condition(ErrorConditionEnum e) noexcept;

    // 19.5.5.3, modifiers
    void assign(int val, const error_category& cat) noexcept;
    template<class ErrorConditionEnum>
      error_condition& operator=(ErrorConditionEnum e) noexcept;
    void clear() noexcept;

    // 19.5.5.4, observers
    int value() const noexcept;
    const error_category& category() const noexcept;
    string message() const;
    explicit operator bool() const noexcept;

  private:
    int val_;                    // exposition only
    const error_category* cat_; // exposition only
  };
}
```

19.5.5.2 Constructors [syserr.errcondition.constructors]

```
error_condition() noexcept;
```

1 *Effects*: Initializes *val_* with 0 and *cat_* with &generic_category().

```
error_condition(int val, const error_category& cat) noexcept;
```

2 *Effects*: Initializes *val_* with val and *cat_* with &cat.

```
template<class ErrorConditionEnum>
  error_condition(ErrorConditionEnum e) noexcept;
```

3 *Constraints*: is_error_condition_enum_v<ErrorConditionEnum> is true.

4 *Effects*: Equivalent to:

```
error_condition ec = make_error_condition(e);
assign(ec.value(), ec.category());
```

19.5.5.3 Modifiers [syserr.errcondition.modifiers]

```
void assign(int val, const error_category& cat) noexcept;
```

1 *Postconditions*: *val_* == val and *cat_* == &cat.

```
template<class ErrorConditionEnum>
  error_condition& operator=(ErrorConditionEnum e) noexcept;
```

2 *Constraints*: is_error_condition_enum_v<ErrorConditionEnum> is true.

3 *Effects*: Equivalent to:

```
error_condition ec = make_error_condition(e);
assign(ec.value(), ec.category());
```

4 *Returns*: *this.

```
void clear() noexcept;
```

5 *Postconditions*: value() == 0 and category() == generic_category().

19.5.5.4 Observers [syserr.errcondition.observers]

```
int value() const noexcept;
```

1 *Returns*: *val_*.

```
const error_category& category() const noexcept;
```

2 *Returns*: **cat_*.

```
string message() const;
```

3 *Returns*: `category().message(value())`.

```
explicit operator bool() const noexcept;
```

4 *Returns*: `value() != 0`.

19.5.5.5 Non-member functions [syserr.errcondition.nonmembers]

```
error_condition make_error_condition(errc e) noexcept;
```

1 *Returns*: `error_condition(static_cast<int>(e), generic_category())`.

19.5.6 Comparison operator functions [syserr.compare]

```
bool operator==(const error_code& lhs, const error_code& rhs) noexcept;
```

1 *Returns*:

```
lhs.category() == rhs.category() && lhs.value() == rhs.value()
```

```
bool operator==(const error_code& lhs, const error_condition& rhs) noexcept;
```

2 *Returns*:

```
lhs.category().equivalent(lhs.value(), rhs) || rhs.category().equivalent(lhs, rhs.value())
```

```
bool operator==(const error_condition& lhs, const error_condition& rhs) noexcept;
```

3 *Returns*:

```
lhs.category() == rhs.category() && lhs.value() == rhs.value()
```

```
strong_ordering operator<=>(const error_code& lhs, const error_code& rhs) noexcept;
```

4 *Effects*: Equivalent to:

```
if (auto c = lhs.category() <=> rhs.category(); c != 0) return c;
return lhs.value() <=> rhs.value();
```

```
strong_ordering operator<=>(const error_condition& lhs, const error_condition& rhs) noexcept;
```

5 *Returns*:

```
if (auto c = lhs.category() <=> rhs.category(); c != 0) return c;
return lhs.value() <=> rhs.value();
```

19.5.7 System error hash support [syserr.hash]

```
template<> struct hash<error_code>;
template<> struct hash<error_condition>;
```

1 The specializations are enabled (22.10.19).

19.5.8 Class `system_error` [syserr.syserr]

19.5.8.1 Overview [syserr.syserr.overview]

1 The class `system_error` describes an exception object used to report error conditions that have an associated error code. Such error conditions typically originate from the operating system or other low-level application program interfaces.

2 [*Note 1*: If an error represents an out-of-memory condition, implementations are encouraged to throw an exception object of type `bad_alloc` (17.6.4.1) rather than `system_error`. — *end note*]

```
namespace std {
  class system_error : public runtime_error {
  public:
    system_error(error_code ec, const string& what_arg);
    system_error(error_code ec, const char* what_arg);
    system_error(error_code ec);
    system_error(int ev, const error_category& ecat, const string& what_arg);
    system_error(int ev, const error_category& ecat, const char* what_arg);
    system_error(int ev, const error_category& ecat);
    const error_code& code() const noexcept;
    const char* what() const noexcept override;
  };
}
```

19.5.8.2 Members [syserr.syserr.members]

`system_error(error_code ec, const string& what_arg);`

1 *Postconditions*: `code() == ec` and `string_view(what()).find(what_arg.c_str()) != string_view::npos`.

`system_error(error_code ec, const char* what_arg);`

2 *Postconditions*: `code() == ec` and `string_view(what()).find(what_arg) != string_view::npos`.

`system_error(error_code ec);`

3 *Postconditions*: `code() == ec`.

`system_error(int ev, const error_category& ecat, const string& what_arg);`

4 *Postconditions*: `code() == error_code(ev, ecat)` and `string_view(what()).find(what_arg.c_str()) != string_view::npos`.

`system_error(int ev, const error_category& ecat, const char* what_arg);`

5 *Postconditions*: `code() == error_code(ev, ecat)` and `string_view(what()).find(what_arg) != string_view::npos`.

`system_error(int ev, const error_category& ecat);`

6 *Postconditions*: `code() == error_code(ev, ecat)`.

`const error_code& code() const noexcept;`

7 *Returns*: `ec` or `error_code(ev, ecat)`, from the constructor, as appropriate.

`const char* what() const noexcept override;`

8 *Returns*: An NTBS incorporating the arguments supplied in the constructor.

[*Note 1*: The returned NTBS might be the contents of `what_arg + ": " + code.message()`. — *end note*]

19.6 Stacktrace [stacktrace]

19.6.1 General [stacktrace.general]

1 Subclause 19.6 describes components that C++ programs may use to store the stacktrace of the current thread of execution and query information about the stored stacktrace at runtime.

2 The *invocation sequence* of the current evaluation x_0 in the current thread of execution is a sequence $(x_0, \ldots, x_n)$ of evaluations such that, for $i \geq 0$, x_i is within the function invocation x_{i+1} (6.10.1).

3 A *stacktrace* is an approximate representation of an invocation sequence and consists of stacktrace entries. A *stacktrace entry* represents an evaluation in a stacktrace.

19.6.2 Header <stacktrace> synopsis [stacktrace.syn]

```
#include <compare>              // see 17.12.1

namespace std {
  // 19.6.3, class stacktrace_entry
  class stacktrace_entry;
```

```
  // 19.6.4, class template basic_stacktrace
  template<class Allocator>
    class basic_stacktrace;

  // basic_stacktrace typedef-names
  using stacktrace = basic_stacktrace<allocator<stacktrace_entry>>;

  // 19.6.4.6, non-member functions
  template<class Allocator>
    void swap(basic_stacktrace<Allocator>& a, basic_stacktrace<Allocator>& b)
      noexcept(noexcept(a.swap(b)));

  string to_string(const stacktrace_entry& f);

  template<class Allocator>
    string to_string(const basic_stacktrace<Allocator>& st);

  ostream& operator<<(ostream& os, const stacktrace_entry& f);
  template<class Allocator>
    ostream& operator<<(ostream& os, const basic_stacktrace<Allocator>& st);

  // 19.6.5, formatting support
  template<> struct formatter<stacktrace_entry>;
  template<class Allocator> struct formatter<basic_stacktrace<Allocator>>;

  namespace pmr {
    using stacktrace = basic_stacktrace<polymorphic_allocator<stacktrace_entry>>;
  }

  // 19.6.6, hash support
  template<class T> struct hash;
  template<> struct hash<stacktrace_entry>;
  template<class Allocator> struct hash<basic_stacktrace<Allocator>>;
}
```

19.6.3 Class `stacktrace_entry` [stacktrace.entry]

19.6.3.1 Overview [stacktrace.entry.overview]

```
namespace std {
  class stacktrace_entry {
  public:
    using native_handle_type = implementation-defined;

    // 19.6.3.2, constructors
    constexpr stacktrace_entry() noexcept;
    constexpr stacktrace_entry(const stacktrace_entry& other) noexcept;
    constexpr stacktrace_entry& operator=(const stacktrace_entry& other) noexcept;

    ~stacktrace_entry();

    // 19.6.3.3, observers
    constexpr native_handle_type native_handle() const noexcept;
    constexpr explicit operator bool() const noexcept;

    // 19.6.3.4, query
    string description() const;
    string source_file() const;
    uint_least32_t source_line() const;

    // 19.6.3.5, comparison
    friend constexpr bool operator==(const stacktrace_entry& x,
                                     const stacktrace_entry& y) noexcept;
    friend constexpr strong_ordering operator<=>(const stacktrace_entry& x,
                                                 const stacktrace_entry& y) noexcept;
```

```
  };
}
```

1 An object of type `stacktrace_entry` is either empty, or represents a stacktrace entry and provides operations for querying information about it. The class `stacktrace_entry` models `regular` (18.6) and `three_way_comparable<strong_ordering>` (17.12.4).

19.6.3.2 Constructors [stacktrace.entry.cons]

```
constexpr stacktrace_entry() noexcept;
```

1 *Postconditions*: `*this` is empty.

19.6.3.3 Observers [stacktrace.entry.obs]

```
constexpr native_handle_type native_handle() const noexcept;
```

1 The semantics of this function are implementation-defined.

2 *Remarks*: Successive invocations of the `native_handle` function for an unchanged `stacktrace_entry` object return identical values.

```
constexpr explicit operator bool() const noexcept;
```

3 *Returns*: `false` if and only if `*this` is empty.

19.6.3.4 Query [stacktrace.entry.query]

1 [*Note 1*: All the `stacktrace_entry` query functions treat errors other than memory allocation errors as "no information available" and do not throw in that case. — *end note*]

```
string description() const;
```

2 *Returns*: A description of the evaluation represented by `*this`, or an empty string.

3 *Throws*: `bad_alloc` if memory for the internal data structures or the resulting string cannot be allocated.

```
string source_file() const;
```

4 *Returns*: The presumed or actual name of the source file (15.12) that lexically contains the expression or statement whose evaluation is represented by `*this`, or an empty string.

5 *Throws*: `bad_alloc` if memory for the internal data structures or the resulting string cannot be allocated.

```
uint_least32_t source_line() const;
```

6 *Returns*: `0`, or a 1-based line number that lexically relates to the evaluation represented by `*this`. If `source_file` returns the presumed name of the source file, returns the presumed line number; if `source_file` returns the actual name of the source file, returns the actual line number.

7 *Throws*: `bad_alloc` if memory for the internal data structures cannot be allocated.

19.6.3.5 Comparison [stacktrace.entry.cmp]

```
friend constexpr bool operator==(const stacktrace_entry& x, const stacktrace_entry& y) noexcept;
```

1 *Returns*: `true` if and only if `x` and `y` represent the same stacktrace entry or both `x` and `y` are empty.

19.6.4 Class template `basic_stacktrace` [stacktrace.basic]

19.6.4.1 Overview [stacktrace.basic.overview]

```
namespace std {
  template<class Allocator>
  class basic_stacktrace {
  public:
    using value_type = stacktrace_entry;
    using const_reference = const value_type&;
    using reference = value_type&;
    using const_iterator = implementation-defined;  // see 19.6.4.3
    using iterator = const_iterator;
    using reverse_iterator = std::reverse_iterator<iterator>;
```

```
    using const_reverse_iterator = std::reverse_iterator<const_iterator>;
    using difference_type = implementation-defined;
    using size_type = implementation-defined;
    using allocator_type = Allocator;

    // 19.6.4.2, creation and assignment
    static basic_stacktrace current(const allocator_type& alloc = allocator_type()) noexcept;
    static basic_stacktrace current(size_type skip,
                                    const allocator_type& alloc = allocator_type()) noexcept;
    static basic_stacktrace current(size_type skip, size_type max_depth,
                                    const allocator_type& alloc = allocator_type()) noexcept;

    basic_stacktrace() noexcept(is_nothrow_default_constructible_v<allocator_type>);
    explicit basic_stacktrace(const allocator_type& alloc) noexcept;

    basic_stacktrace(const basic_stacktrace& other);
    basic_stacktrace(basic_stacktrace&& other) noexcept;
    basic_stacktrace(const basic_stacktrace& other, const allocator_type& alloc);
    basic_stacktrace(basic_stacktrace&& other, const allocator_type& alloc);
    basic_stacktrace& operator=(const basic_stacktrace& other);
    basic_stacktrace& operator=(basic_stacktrace&& other)
      noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
        allocator_traits<Allocator>::is_always_equal::value);

    ~basic_stacktrace();

    // 19.6.4.3, observers
    allocator_type get_allocator() const noexcept;

    const_iterator begin() const noexcept;
    const_iterator end() const noexcept;
    const_reverse_iterator rbegin() const noexcept;
    const_reverse_iterator rend() const noexcept;

    const_iterator cbegin() const noexcept;
    const_iterator cend() const noexcept;
    const_reverse_iterator crbegin() const noexcept;
    const_reverse_iterator crend() const noexcept;

    bool empty() const noexcept;
    size_type size() const noexcept;
    size_type max_size() const noexcept;

    const_reference operator[](size_type) const;
    const_reference at(size_type) const;

    // 19.6.4.4, comparisons
    template<class Allocator2>
    friend bool operator==(const basic_stacktrace& x,
                           const basic_stacktrace<Allocator2>& y) noexcept;
    template<class Allocator2>
    friend strong_ordering operator<=>(const basic_stacktrace& x,
                                       const basic_stacktrace<Allocator2>& y) noexcept;

    // 19.6.4.5, modifiers
    void swap(basic_stacktrace& other)
      noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
        allocator_traits<Allocator>::is_always_equal::value);

  private:
    vector<value_type, allocator_type> frames_;          // exposition only
  };
}
```

1 The class template `basic_stacktrace` satisfies the requirements of a reversible container (23.2.2.3), of an allocator-aware container (23.2.2.5), and of a sequence container (23.2.4), except that

(1.1) — only move, assignment, swap, and operations defined for const-qualified sequence containers are supported and,

(1.2) — the semantics of comparison functions are different from those required for a container.

19.6.4.2 Creation and assignment [stacktrace.basic.cons]

```
static basic_stacktrace current(const allocator_type& alloc = allocator_type()) noexcept;
```

1 *Returns*: A `basic_stacktrace` object with *`frames_`* storing the stacktrace of the current evaluation in the current thread of execution, or an empty `basic_stacktrace` object if the initialization of *`frames_`* failed. `alloc` is passed to the constructor of the *`frames_`* object.

[*Note 1*: If the stacktrace was successfully obtained, then *`frames_`*`.front()` is the `stacktrace_entry` representing approximately the current evaluation, and *`frames_`*`.back()` is the `stacktrace_entry` representing approximately the initial function of the current thread of execution. — *end note*]

```
static basic_stacktrace current(size_type skip,
                                const allocator_type& alloc = allocator_type()) noexcept;
```

2 Let `t` be a stacktrace as-if obtained via `basic_stacktrace::current(alloc)`. Let `n` be `t.size()`.

3 *Returns*: A `basic_stacktrace` object where *`frames_`* is direct-non-list-initialized from arguments `t.begin() + min(n, skip)`, `t.end()`, and `alloc`, or an empty `basic_stacktrace` object if the initialization of *`frames_`* failed.

```
static basic_stacktrace current(size_type skip, size_type max_depth,
                                const allocator_type& alloc = allocator_type()) noexcept;
```

4 Let `t` be a stacktrace as-if obtained via `basic_stacktrace::current(alloc)`. Let `n` be `t.size()`.

5 *Hardened preconditions*: `skip <= skip + max_depth` is `true`.

6 *Returns*: A `basic_stacktrace` object where *`frames_`* is direct-non-list-initialized from arguments `t.begin() + min(n, skip)`, `t.begin() + min(n, skip + max_depth)`, and `alloc`, or an empty `basic_stacktrace` object if the initialization of *`frames_`* failed.

```
basic_stacktrace() noexcept(is_nothrow_default_constructible_v<allocator_type>);
```

7 *Postconditions*: `empty()` is `true`.

```
explicit basic_stacktrace(const allocator_type& alloc) noexcept;
```

8 *Effects*: `alloc` is passed to the *`frames_`* constructor.

9 *Postconditions*: `empty()` is `true`.

```
basic_stacktrace(const basic_stacktrace& other);
basic_stacktrace(const basic_stacktrace& other, const allocator_type& alloc);
basic_stacktrace(basic_stacktrace&& other, const allocator_type& alloc);
basic_stacktrace& operator=(const basic_stacktrace& other);
basic_stacktrace& operator=(basic_stacktrace&& other)
  noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
    allocator_traits<Allocator>::is_always_equal::value);
```

10 *Remarks*: Implementations may strengthen the exception specification for these functions (16.4.6.14) by ensuring that `empty()` is `true` on failed allocation.

19.6.4.3 Observers [stacktrace.basic.obs]

```
using const_iterator = implementation-defined;
```

1 The type models `random_access_iterator` (24.3.4.13) and meets the *Cpp17RandomAccessIterator* requirements (24.3.5.7).

```
allocator_type get_allocator() const noexcept;
```

2 *Returns*: *`frames_`*`.get_allocator()`.

```
const_iterator begin() const noexcept;
const_iterator cbegin() const noexcept;
```

3 *Returns*: An iterator referring to the first element in *frames_*. If `empty()` is `true`, then it returns the same value as `end()`.

```
const_iterator end() const noexcept;
const_iterator cend() const noexcept;
```

4 *Returns*: The end iterator.

```
const_reverse_iterator rbegin() const noexcept;
const_reverse_iterator crbegin() const noexcept;
```

5 *Returns*: `reverse_iterator(cend())`.

```
const_reverse_iterator rend() const noexcept;
const_reverse_iterator crend() const noexcept;
```

6 *Returns*: `reverse_iterator(cbegin())`.

```
bool empty() const noexcept;
```

7 *Returns*: *frames_*`.empty()`.

```
size_type size() const noexcept;
```

8 *Returns*: *frames_*`.size()`.

```
size_type max_size() const noexcept;
```

9 *Returns*: *frames_*`.max_size()`.

```
const_reference operator[](size_type frame_no) const;
```

10 *Hardened preconditions*: `frame_no < size()` is `true`.

11 *Returns*: *frames_*`[frame_no]`.

12 *Throws*: Nothing.

```
const_reference at(size_type frame_no) const;
```

13 *Returns*: *frames_*`[frame_no]`.

14 *Throws*: `out_of_range` if `frame_no >= size()`.

19.6.4.4 Comparisons [stacktrace.basic.cmp]

```
template<class Allocator2>
friend bool operator==(const basic_stacktrace& x, const basic_stacktrace<Allocator2>& y) noexcept;
```

1 *Returns*: `equal(x.begin(), x.end(), y.begin(), y.end())`.

```
template<class Allocator2>
friend strong_ordering
  operator<=>(const basic_stacktrace& x, const basic_stacktrace<Allocator2>& y) noexcept;
```

2 *Returns*: `x.size() <=> y.size()` if `x.size() != y.size()`; `lexicographical_compare_three_-way(x.begin(), x.end(), y.begin(), y.end())` otherwise.

19.6.4.5 Modifiers [stacktrace.basic.mod]

```
void swap(basic_stacktrace& other)
  noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
    allocator_traits<Allocator>::is_always_equal::value);
```

1 *Effects*: Exchanges the contents of `*this` and `other`.

19.6.4.6 Non-member functions [stacktrace.basic.nonmem]

```
template<class Allocator>
  void swap(basic_stacktrace<Allocator>& a, basic_stacktrace<Allocator>& b)
    noexcept(noexcept(a.swap(b)));
```

1 *Effects*: Equivalent to `a.swap(b)`.

```
string to_string(const stacktrace_entry& f);
```

2 *Returns*: A string with a description of `f`.

3 *Recommended practice*: The description should provide information about the contained evaluation, including information from `f.source_file()` and `f.source_line()`.

```
template<class Allocator>
  string to_string(const basic_stacktrace<Allocator>& st);
```

4 *Returns*: A string with a description of `st`.

[*Note 1*: The number of lines is not guaranteed to be equal to `st.size()`. — *end note*]

```
ostream& operator<<(ostream& os, const stacktrace_entry& f);
```

5 *Effects*: Equivalent to: `return os << to_string(f);`

```
template<class Allocator>
  ostream& operator<<(ostream& os, const basic_stacktrace<Allocator>& st);
```

6 *Effects*: Equivalent to: `return os << to_string(st);`

19.6.5 Formatting support [stacktrace.format]

```
template<> struct formatter<stacktrace_entry>;
```

1 `formatter<stacktrace_entry>` interprets *format-spec* as a *stacktrace-entry-format-spec*. The syntax of format specifications is as follows:

stacktrace-entry-format-spec:
fill-and-align$_{opt}$ *width*$_{opt}$

[*Note 1*: The productions *fill-and-align* and *width* are described in 28.5.2.2. — *end note*]

2 A `stacktrace_entry` object `se` is formatted as if by copying `to_string(se)` through the output iterator of the context with additional padding and adjustments as specified by the format specifiers.

```
template<class Allocator> struct formatter<basic_stacktrace<Allocator>>;
```

3 For `formatter<basic_stacktrace<Allocator>>`, *format-spec* is empty.

4 A `basic_stacktrace<Allocator>` object `s` is formatted as if by copying `to_string(s)` through the output iterator of the context.

19.6.6 Hash support [stacktrace.basic.hash]

```
template<> struct hash<stacktrace_entry>;
template<class Allocator> struct hash<basic_stacktrace<Allocator>>;
```

1 The specializations are enabled (22.10.19).

19.7 Debugging [debugging]

19.7.1 General [debugging.general]

1 Subclause 19.7 describes functionality to introspect and interact with the execution of the program.

[*Note 1*: The facilities provided by the debugging functionality interact with a program that could be tracing the execution of a C++ program, such as a debugger. — *end note*]

19.7.2 Header <debugging> synopsis [debugging.syn]

```
// all freestanding
namespace std {
  // 19.7.3, utility
  void breakpoint() noexcept;
```

```
  void breakpoint_if_debugging() noexcept;
  bool is_debugger_present() noexcept;
}
```

19.7.3 Utility [debugging.utility]

`void breakpoint() noexcept;`

1 The semantics of this function are implementation-defined.

[*Note 1*: It is intended that, when invoked with a debugger present, the execution of the program temporarily halts and execution is handed to the debugger until the program is either terminated by the debugger or the debugger resumes execution of the program as if the function was not invoked. In particular, there is no intent for a call to this function to accomodate resumption of the program in a different manner. If there is no debugger present, execution of the program can end abnormally. — *end note*]

`void breakpoint_if_debugging() noexcept;`

2 *Effects*: Equivalent to:

```
if (is_debugger_present()) breakpoint();
```

`bool is_debugger_present() noexcept;`

3 *Required behavior*: This function has no preconditions.

4 *Default behavior*: implementation-defined.

[*Note 2*: It is intended that, using an immediate (uncached) query to determine if the program is being traced by a debugger, an implementation returns `true` only when tracing the execution of the program with a debugger. On Windows or equivalent systems, this can be achieved by calling the `::IsDebuggerPresent()` Win32 function. For systems compatible with ISO/IEC 23360:2021, this can be achieved by checking for a tracing process, with a best-effort determination that such a tracing process is a debugger. — *end note*]

5 *Remarks*: This function is replaceable (9.6.5).

20 Memory management library [mem]

20.1 General [mem.general]

1 This Clause describes components for memory management.

2 The following subclauses describe general memory management facilities, smart pointers, memory resources, and scoped allocators, as summarized in Table 50.

Table 50 — Memory management library summary [tab:mem.summary]

	Subclause	Header
20.2	Memory	`<cstdlib>`, `<memory>`
20.3	Smart pointers	`<memory>`
20.4	Types for composite class design	`<memory>`
20.5	Memory resources	`<memory_resource>`
20.6	Scoped allocators	`<scoped_allocator>`

20.2 Memory [memory]

20.2.1 General [memory.general]

1 Subclause 20.2 describes the contents of the header `<memory>` (20.2.2) and some of the contents of the header `<cstdlib>` (17.2.2).

20.2.2 Header `<memory>` synopsis [memory.syn]

1 The header `<memory>` defines several types and function templates that describe properties of pointers and pointer-like types, manage memory for containers and other template types, destroy objects, and construct objects in uninitialized memory buffers (20.2.3–20.2.11 and 26.11). The header also defines the templates `unique_ptr`, `shared_ptr`, `weak_ptr`, `out_ptr_t`, `inout_ptr_t`, and various function templates that operate on objects of these types (20.3).

2 Let *`POINTER_OF`*`(T)` denote a type that is

(2.1) — `T::pointer` if the *qualified-id* `T::pointer` is valid and denotes a type,

(2.2) — otherwise, `T::element_type*` if the *qualified-id* `T::element_type` is valid and denotes a type,

(2.3) — otherwise, `pointer_traits<T>::element_type*`.

3 Let *`POINTER_OF_OR`*`(T, U)` denote a type that is:

(3.1) — *`POINTER_OF`*`(T)` if *`POINTER_OF`*`(T)` is valid and denotes a type,

(3.2) — otherwise, `U`.

```
#include <compare>              // see 17.12.1

namespace std {
  // 20.2.3, pointer traits
  template<class Ptr> struct pointer_traits;                                  // freestanding
  template<class T> struct pointer_traits<T*>;                                // freestanding

  // 20.2.4, pointer conversion
  template<class T>
    constexpr T* to_address(T* p) noexcept;                                   // freestanding
  template<class Ptr>
    constexpr auto to_address(const Ptr& p) noexcept;                         // freestanding

  // 20.2.5, pointer alignment
  void* align(size_t alignment, size_t size, void*& ptr, size_t& space);      // freestanding
  template<size_t N, class T>
    constexpr T* assume_aligned(T* ptr);                                      // freestanding
```

```
template<size_t Alignment, class T>
  bool is_sufficiently_aligned(T* ptr);                                          // freestanding

// 20.2.6, explicit lifetime management
template<class T>
  constexpr void start_lifetime(T& r) noexcept;                                  // freestanding
template<class T>
  T* start_lifetime_as(void* p) noexcept;                                        // freestanding
template<class T>
  const T* start_lifetime_as(const void* p) noexcept;                            // freestanding
template<class T>

  }
}
```

20.2.3 Pointer traits [pointer.traits]

20.2.3.1 General [pointer.traits.general]

1 The class template `pointer_traits` supplies a uniform interface to certain attributes of pointer-like types.

```
namespace std {
  template<class Ptr> struct pointer_traits {
    see below;
  };

  template<class T> struct pointer_traits<T*> {
    using pointer         = T*;
    using element_type    = T;
    using difference_type = ptrdiff_t;

    template<class U> using rebind = U*;

    static constexpr pointer pointer_to(see below r) noexcept;
  };
}
```

20.2.3.2 Member types [pointer.traits.types]

1 The definitions in this subclause make use of the following exposition-only class template and concept:

```
template<class T>
struct ptr-traits-elem          // exposition only
{ };

template<class T> requires requires { typename T::element_type; }
struct ptr-traits-elem<T>
{ using type = T::element_type; };

template<template<class...> class SomePointer, class T, class... Args>
  requires (!requires { typename SomePointer<T, Args...>::element_type; })
struct ptr-traits-elem<SomePointer<T, Args...>>
{ using type = T; };

template<class Ptr>
  concept has-elem-type =       // exposition only
    requires { typename ptr-traits-elem<Ptr>::type; }
```

2 If `Ptr` satisfies *`has-elem-type`*, a specialization `pointer_traits<Ptr>` generated from the `pointer_traits` primary template has the following members as well as those described in 20.2.3.3; otherwise, such a specialization has no members by any of those names.

`using pointer = see below;`

3 *Type*: `Ptr`.

`using element_type = see below;`

4 *Type*: `typename ptr-traits-elem<Ptr>::type`.

`using difference_type = see below;`

5 *Type*: `Ptr::difference_type` if the *qualified-id* `Ptr::difference_type` is valid and denotes a type (13.10.3); otherwise, `ptrdiff_t`.

`template<class U> using rebind = see below;`

6 *Alias template*: `Ptr::rebind<U>` if the *qualified-id* `Ptr::rebind<U>` is valid and denotes a type (13.10.3); otherwise, `SomePointer<U, Args>` if `Ptr` is a class template specialization of the form `SomePointer<T, Args>`, where `Args` is zero or more type arguments; otherwise, the instantiation of `rebind` is ill-formed.

20.2.3.3 Member functions [pointer.traits.functions]

```
static constexpr pointer pointer_traits::pointer_to(see below r);
static constexpr pointer pointer_traits<T*>::pointer_to(see below r) noexcept;
```

1 *Mandates*: For the first member function, `Ptr::pointer_to(r)` is well-formed.

2 *Preconditions*: For the first member function, `Ptr::pointer_to(r)` returns a pointer to `r` through which indirection is valid.

3 *Returns*: The first member function returns `Ptr::pointer_to(r)`. The second member function returns `addressof(r)`.

4 *Remarks*: If `element_type` is *cv* `void`, the type of `r` is unspecified; otherwise, it is `element_type&`.

20.2.3.4 Optional members [pointer.traits.optmem]

1 Specializations of `pointer_traits` may define the member declared in this subclause to customize the behavior of the standard library. A specialization generated from the `pointer_traits` primary template has no member by this name.

`static element_type* to_address(pointer p) noexcept;`

2 *Returns*: A pointer of type `element_type*` that references the same location as the argument `p`.

3 [*Note 1*: This function is intended to be the inverse of `pointer_to`. If defined, it customizes the behavior of the non-member function `to_address` (20.2.4). — *end note*]

20.2.4 Pointer conversion [pointer.conversion]

`template<class T> constexpr T* to_address(T* p) noexcept;`

1 *Mandates*: `T` is not a function type.

2 *Returns*: `p`.

`template<class Ptr> constexpr auto to_address(const Ptr& p) noexcept;`

3 *Returns*: `pointer_traits<Ptr>::to_address(p)` if that expression is well-formed (see 20.2.3.4), otherwise `to_address(p.operator->())`.

20.2.5 Pointer alignment [ptr.align]

`void* align(size_t alignment, size_t size, void*& ptr, size_t& space);`

1 *Preconditions*:

(1.1) — `alignment` is a power of two

(1.2) — `ptr` represents the address of contiguous storage of at least `space` bytes

2 *Effects*: If it is possible to fit `size` bytes of storage aligned by `alignment` into the buffer pointed to by `ptr` with length `space`, the function updates `ptr` to represent the first possible address of such storage and decreases `space` by the number of bytes used for alignment. Otherwise, the function does nothing.

3 *Returns*: A null pointer if the requested aligned buffer would not fit into the available space, otherwise the adjusted value of `ptr`.

4 [*Note 1*: The function updates its `ptr` and `space` arguments so that it can be called repeatedly with possibly different `alignment` and `size` arguments for the same buffer. — *end note*]

```
template<size_t N, class T>
  constexpr T* assume_aligned(T* ptr);
```

5 *Mandates*: `N` is a power of two.

6 *Preconditions*: `ptr` points to an object X of a type similar (7.3.6) to `T`, where X has alignment `N` (6.8.3).

7 *Returns*: `ptr`.

8 *Throws*: Nothing.

9 [*Note 2*: The alignment assumption on an object X expressed by a call to `assume_aligned` might result in generation of more efficient code. It is up to the program to ensure that the assumption actually holds. The call does not cause the implementation to verify or enforce this. An implementation might only make the assumption for those operations on X that access X through the pointer returned by `assume_aligned`. — *end note*]

```
template<size_t Alignment, class T>
  bool is_sufficiently_aligned(T* ptr);
```

10 *Mandates*: `Alignment` is a power of two.

11 *Preconditions*: `p` points to an object `X` of a type similar (7.3.6) to `T`.

12 *Returns*: `true` if `X` has alignment at least `Alignment`, otherwise `false`.

13 *Throws*: Nothing.

20.2.6 Explicit lifetime management [obj.lifetime]

```
template<class T>
  constexpr void start_lifetime(T& r) noexcept;
```

1 *Mandates*: `T` is a complete type and an implicit-lifetime (6.9) aggregate (9.5.2) type.

2 *Effects*: If the object referenced by `r` is already within its lifetime (6.8.4), no effects. Otherwise, begins the lifetime of the object referenced by `r`.

[*Note 1*: No initialization is performed and no subobject has its lifetime started. If `r` denotes a member of a union U, it becomes the active member of U (11.5). — *end note*]

```
template<class T>
  T* start_lifetime_as(void* p) noexcept;
template<class T>
  const T* start_lifetime_as(const void* p) noexcept;
template<class T>
  volatile T* start_lifetime_as(volatile void* p) noexcept;
template<class T>
  const volatile T* start_lifetime_as(const volatile void* p) noexcept;
```

3 *Mandates*: `T` is an implicit-lifetime type (6.9.1) and not an incomplete type (6.9.1).

4 *Preconditions*: [`p`, `(char*)p + sizeof(T)`) denotes a region of allocated storage that is a subset of the region of storage reachable through (6.9.4) `p` and suitably aligned for the type `T`.

5 *Effects*: Implicitly creates objects (6.8.2) within the denoted region consisting of an object a of type `T` whose address is `p`, and objects nested within a, as follows: The object representation of a is the contents of the storage prior to the call to `start_lifetime_as`. The value of each created object o of trivially copyable type (6.9.1) `U` is determined in the same manner as for a call to `bit_cast<U>(E)` (22.11.3), where `E` is an lvalue of type `U` denoting o, except that the storage is not accessed. The value of any other created object is unspecified.

[*Note 2*: The unspecified value can be indeterminate. — *end note*]

6 *Returns*: A pointer to the a defined in the *Effects* paragraph.

```
template<class T>
  T* start_lifetime_as_array(void* p, size_t n) noexcept;
```

```
template<class T>
  const T* start_lifetime_as_array(const void* p, size_t n) noexcept;
template<class T>
  volatile T* start_lifetime_as_array(volatile void* p, size_t n) noexcept;
template<class T>
  const volatile T* start_lifetime_as_array(const volatile void* p, size_t n) noexcept;
```

7 *Mandates*: `T` is a complete type.

8 *Preconditions*: `p` is suitably aligned for an array of `T` or is null. `n <= size_t(-1) / sizeof(T)` is `true`. If `n > 0` is `true`, [`(char*)p`, `(char*)p + (n * sizeof(T))`) denotes a region of allocated storage that is a subset of the region of storage reachable through (6.9.4) `p`.

9 *Effects*: If `n > 0` is `true`, equivalent to `start_lifetime_as<U>(p)` where `U` is the type "array of `n` `T`". Otherwise, there are no effects.

10 *Returns*: A pointer to the first element of the created array, if any; otherwise, a pointer that compares equal to `p` (7.6.10).

20.2.7 Allocator argument tag [allocator.tag]

```
namespace std {
  struct allocator_arg_t { explicit allocator_arg_t() = default; };
  inline constexpr allocator_arg_t allocator_arg{};
}
```

1 The `allocator_arg_t` struct is an empty class type used as a unique type to disambiguate constructor and function overloading. Specifically, several types (see `tuple` 22.4) have constructors with `allocator_arg_t` as the first argument, immediately followed by an argument of a type that meets the *Cpp17Allocator* requirements (16.4.4.6.1).

20.2.8 `uses_allocator` [allocator.uses]

20.2.8.1 `uses_allocator` trait [allocator.uses.trait]

```
template<class T, class Alloc> struct uses_allocator;
```

1 *Remarks*: Automatically detects whether `T` has a nested `allocator_type` that is convertible from `Alloc`. Meets the *Cpp17BinaryTypeTrait* requirements (21.3.2). The implementation shall provide a definition that is derived from `true_type` if the *qualified-id* `T::allocator_type` is valid and denotes a type (13.10.3) and `is_convertible_v<Alloc, T::allocator_type> != false`, otherwise it shall be derived from `false_type`. A program may specialize this template to derive from `true_type` for a program-defined type `T` that does not have a nested `allocator_type` but nonetheless can be constructed with an allocator where either:

(1.1) — the first argument of a constructor has type `allocator_arg_t` and the second argument has type `Alloc` or

(1.2) — the last argument of a constructor has type `Alloc`.

20.2.8.2 Uses-allocator construction [allocator.uses.construction]

1 *Uses-allocator construction* with allocator `alloc` and constructor arguments `args...` refers to the construction of an object of type `T` such that `alloc` is passed to the constructor of `T` if `T` uses an allocator type compatible with `alloc`. When applied to the construction of an object of type `T`, it is equivalent to initializing it with the value of the expression `make_obj_using_allocator<T>(alloc, args...)`, described below.

2 The following utility functions support three conventions for passing `alloc` to a constructor:

(2.1) — If `T` does not use an allocator compatible with `alloc`, then `alloc` is ignored.

(2.2) — Otherwise, if `T` has a constructor invocable as `T(allocator_arg_t{}, alloc, args...)` (leading-allocator convention), then uses-allocator construction chooses this constructor form.

(2.3) — Otherwise, if `T` has a constructor invocable as `T(args..., alloc)` (trailing-allocator convention), then uses-allocator construction chooses this constructor form.

3 The `uses_allocator_construction_args` function template takes an allocator and argument list and produces (as a tuple) a new argument list matching one of the above conventions. Additionally, overloads are provided that treat specializations of `pair` such that uses-allocator construction is applied individually to

the `first` and `second` data members. The `make_obj_using_allocator` and `uninitialized_construct_using_allocator` function templates apply the modified constructor arguments to construct an object of type `T` as a return value or in-place, respectively.

[*Note 1*: For `uses_allocator_construction_args` and `make_obj_using_allocator`, type `T` is not deduced and must therefore be specified explicitly by the caller. — *end note*]

```
template<class T, class Alloc, class... Args>
  constexpr auto uses_allocator_construction_args(const Alloc& alloc,
                                                  Args&&... args) noexcept;
```

4 *Constraints*: `remove_cv_t<T>` is not a specialization of `pair`.

5 *Returns*: A `tuple` value determined as follows:

(5.1) — If `uses_allocator_v<remove_cv_t<T>, Alloc>` is `false` and `is_constructible_v<T, Args...>` is `true`, return `forward_as_tuple(std::forward<Args>(args)...)`.

(5.2) — Otherwise, if `uses_allocator_v<remove_cv_t<T>, Alloc>` is `true` and `is_constructible_v<T, allocator_arg_t, const Alloc&, Args...>` is `true`, return

```
tuple<allocator_arg_t, const Alloc&, Args&&...>(
  allocator_arg, alloc, std::forward<Args>(args)...)
```

(5.3) — Otherwise, if `uses_allocator_v<remove_cv_t<T>, Alloc>` is `true` and `is_constructible_v<T, Args..., const Alloc&>` is `true`, return `forward_as_tuple(std::forward<Args>(args)..., alloc)`.

(5.4) — Otherwise, the program is ill-formed.

[*Note 2*: This definition prevents a silent failure to pass the allocator to a constructor of a type for which `uses_allocator_v<T, Alloc>` is `true`. — *end note*]

```
template<class T, class Alloc, class Tuple1, class Tuple2>
  constexpr auto uses_allocator_construction_args(const Alloc& alloc, piecewise_construct_t,
                                                  Tuple1&& x, Tuple2&& y) noexcept;
```

6 Let `T1` be `T::first_type`. Let `T2` be `T::second_type`.

7 *Constraints*: `remove_cv_t<T>` is a specialization of `pair`.

8 *Effects*: Equivalent to:

```
return make_tuple(
  piecewise_construct,
  apply([&alloc](auto&&... args1) {
          return uses_allocator_construction_args<T1>(
            alloc, std::forward<decltype(args1)>(args1)...);
        }, std::forward<Tuple1>(x)),
  apply([&alloc](auto&&... args2) {
          return uses_allocator_construction_args<T2>(
            alloc, std::forward<decltype(args2)>(args2)...);
        }, std::forward<Tuple2>(y)));
```

```
template<class T, class Alloc>
  constexpr auto uses_allocator_construction_args(const Alloc& alloc) noexcept;
```

9 *Constraints*: `remove_cv_t<T>` is a specialization of `pair`.

10 *Effects*: Equivalent to:

```
return uses_allocator_construction_args<T>(alloc, piecewise_construct,
                                           tuple<>{}, tuple<>{});
```

```
template<class T, class Alloc, class U, class V>
  constexpr auto uses_allocator_construction_args(const Alloc& alloc,
                                                  U&& u, V&& v) noexcept;
```

11 *Constraints*: `remove_cv_t<T>` is a specialization of `pair`.

12 *Effects*: Equivalent to:

```
return uses_allocator_construction_args<T>(alloc, piecewise_construct,
                                           forward_as_tuple(std::forward<U>(u)),
```

```
                                                forward_as_tuple(std::forward<V>(v)));

template<class T, class Alloc, class U, class V>
  constexpr auto uses_allocator_construction_args(const Alloc& alloc,
                                                  pair<U, V>& pr) noexcept;
template<class T, class Alloc, class U, class V>
  constexpr auto uses_allocator_construction_args(const Alloc& alloc,
                                                  const pair<U, V>& pr) noexcept;
```

13 *Constraints*: `remove_cv_t<T>` is a specialization of `pair`.

14 *Effects*: Equivalent to:

```
return uses_allocator_construction_args<T>(alloc, piecewise_construct,
                                           forward_as_tuple(pr.first),
                                           forward_as_tuple(pr.second));
```

```
template<class T, class Alloc, class U, class V>
  constexpr auto uses_allocator_construction_args(const Alloc& alloc,
                                                  pair<U, V>&& pr) noexcept;
template<class T, class Alloc, class U, class V>
  constexpr auto uses_allocator_construction_args(const Alloc& alloc,
                                                  const pair<U, V>&& pr) noexcept;
```

15 *Constraints*: `remove_cv_t<T>` is a specialization of `pair`.

16 *Effects*: Equivalent to:

```
return uses_allocator_construction_args<T>(alloc, piecewise_construct,
                                           forward_as_tuple(get<0>(std::move(pr))),
                                           forward_as_tuple(get<1>(std::move(pr))));
```

```
template<class T, class Alloc, pair-like P>
  constexpr auto uses_allocator_construction_args(const Alloc& alloc, P&& p) noexcept;
```

17 *Constraints*: `remove_cv_t<T>` is a specialization of `pair` and `remove_cvref_t<P>` is not a specialization of `ranges::subrange`.

18 *Effects*: Equivalent to:

```
return uses_allocator_construction_args<T>(alloc, piecewise_construct,
                                           forward_as_tuple(get<0>(std::forward<P>(p))),
                                           forward_as_tuple(get<1>(std::forward<P>(p))));
```

```
template<class T, class Alloc, class U>
  constexpr auto uses_allocator_construction_args(const Alloc& alloc, U&& u) noexcept;
```

19 Let *FUN* be the function template:

```
template<class A, class B>
  void FUN(const pair<A, B>&);
```

20 *Constraints*: `remove_cv_t<T>` is a specialization of `pair`, and either:

(20.1) — `remove_cvref_t<U>` is a specialization of `ranges::subrange`, or

(20.2) — `U` does not satisfy *pair-like* and the expression *FUN*`(u)` is not well-formed when considered as an unevaluated operand.

21 Let *pair-constructor* be an exposition-only class defined as follows:

```
class pair-constructor {
  using pair-type = remove_cv_t<T>;                          // exposition only

  constexpr auto do-construct(const pair-type& p) const {    // exposition only
    return make_obj_using_allocator<pair-type>(alloc_, p);
  }
  constexpr auto do-construct(pair-type&& p) const {         // exposition only
    return make_obj_using_allocator<pair-type>(alloc_, std::move(p));
  }

  const Alloc& alloc_;  // exposition only
  U& u_;                // exposition only
```

```
  public:
    constexpr operator pair-type() const {
      return do-construct(std::forward<U>(u_));
    }
  };
```

22 *Returns*: `make_tuple(pc)`, where `pc` is a *`pair-constructor`* object whose *`alloc_`* member is initialized with `alloc` and whose *`u_`* member is initialized with `u`.

```
template<class T, class Alloc, class... Args>
  constexpr T make_obj_using_allocator(const Alloc& alloc, Args&&... args);
```

23 *Effects*: Equivalent to:

```
  return make_from_tuple<T>(uses_allocator_construction_args<T>(
                              alloc, std::forward<Args>(args)...));
```

```
template<class T, class Alloc, class... Args>
  constexpr T* uninitialized_construct_using_allocator(T* p, const Alloc& alloc, Args&&... args);
```

24 *Effects*: Equivalent to:

```
  return apply([&]<class... U>(U&&... xs) {
         return construct_at(p, std::forward<U>(xs)...);
       }, uses_allocator_construction_args<T>(alloc, std::forward<Args>(args)...));
```

20.2.9 Allocator traits [allocator.traits]

20.2.9.1 General [allocator.traits.general]

1 The class template `allocator_traits` supplies a uniform interface to all allocator types. An allocator cannot be a non-class type, however, even if `allocator_traits` supplies the entire required interface.

[*Note 1*: Thus, it is always possible to create a derived class from an allocator. — *end note*]

If a program declares an explicit or partial specialization of `allocator_traits`, the program is ill-formed, no diagnostic required.

```
namespace std {
  template<class Alloc> struct allocator_traits {
    using allocator_type     = Alloc;

    using value_type         = Alloc::value_type;

    using pointer            = see below;
    using const_pointer      = see below;
    using void_pointer       = see below;
    using const_void_pointer = see below;

    using difference_type    = see below;
    using size_type          = see below;

    using propagate_on_container_copy_assignment = see below;
    using propagate_on_container_move_assignment = see below;
    using propagate_on_container_swap            = see below;
    using is_always_equal                        = see below;

    template<class T> using rebind_alloc = see below;
    template<class T> using rebind_traits = allocator_traits<rebind_alloc<T>>;

    static constexpr pointer allocate(Alloc& a, size_type n);
    static constexpr pointer allocate(Alloc& a, size_type n, const_void_pointer hint);
    static constexpr allocation_result<pointer, size_type>
      allocate_at_least(Alloc& a, size_type n);

    static constexpr void deallocate(Alloc& a, pointer p, size_type n);

    template<class T, class... Args>
      static constexpr void construct(Alloc& a, T* p, Args&&... args);
```

```
    template<class T>
      static constexpr void destroy(Alloc& a, T* p);

    static constexpr size_type max_size(const Alloc& a) noexcept;

    static constexpr Alloc select_on_container_copy_construction(const Alloc& rhs);
  };
}
```

20.2.9.2 Member types [allocator.traits.types]

```
using pointer = see below;
```

1 *Type*: `Alloc::pointer` if the *qualified-id* `Alloc::pointer` is valid and denotes a type (13.10.3); otherwise, `value_type*`.

```
using const_pointer = see below;
```

2 *Type*: `Alloc::const_pointer` if the *qualified-id* `Alloc::const_pointer` is valid and denotes a type (13.10.3); otherwise, `pointer_traits<pointer>::rebind<const value_type>`.

```
using void_pointer = see below;
```

3 *Type*: `Alloc::void_pointer` if the *qualified-id* `Alloc::void_pointer` is valid and denotes a type (13.10.3); otherwise, `pointer_traits<pointer>::rebind<void>`.

```
using const_void_pointer = see below;
```

4 *Type*: `Alloc::const_void_pointer` if the *qualified-id* `Alloc::const_void_pointer` is valid and denotes a type (13.10.3); otherwise, `pointer_traits<pointer>::rebind<const void>`.

```
using difference_type = see below;
```

5 *Type*: `Alloc::difference_type` if the *qualified-id* `Alloc::difference_type` is valid and denotes a type (13.10.3); otherwise, `pointer_traits<pointer>::difference_type`.

```
using size_type = see below;
```

6 *Type*: `Alloc::size_type` if the *qualified-id* `Alloc::size_type` is valid and denotes a type (13.10.3); otherwise, `make_unsigned_t<difference_type>`.

```
using propagate_on_container_copy_assignment = see below;
```

7 *Type*: `Alloc::propagate_on_container_copy_assignment` if the *qualified-id* `Alloc::propagate_on_container_copy_assignment` is valid and denotes a type (13.10.3); otherwise `false_type`.

```
using propagate_on_container_move_assignment = see below;
```

8 *Type*: `Alloc::propagate_on_container_move_assignment` if the *qualified-id* `Alloc::propagate_on_container_move_assignment` is valid and denotes a type (13.10.3); otherwise `false_type`.

```
using propagate_on_container_swap = see below;
```

9 *Type*: `Alloc::propagate_on_container_swap` if the *qualified-id* `Alloc::propagate_on_container_swap` is valid and denotes a type (13.10.3); otherwise `false_type`.

```
using is_always_equal = see below;
```

10 *Type*: `Alloc::is_always_equal` if the *qualified-id* `Alloc::is_always_equal` is valid and denotes a type (13.10.3); otherwise `is_empty<Alloc>::type`.

```
template<class T> using rebind_alloc = see below;
```

11 *Alias template*: `Alloc::rebind<T>::other` if the *qualified-id* `Alloc::rebind<T>::other` is valid and denotes a type (13.10.3); otherwise, `Alloc<T, Args>` if `Alloc` is a class template specialization of the form `Alloc<U, Args>`, where `Args` is zero or more type arguments; otherwise, the instantiation of `rebind_alloc` is ill-formed.

20.2.9.3 Static member functions [allocator.traits.members]

```
static constexpr pointer allocate(Alloc& a, size_type n);
```

1 *Returns*: `a.allocate(n)`.

```
static constexpr pointer allocate(Alloc& a, size_type n, const_void_pointer hint);
```

2 *Returns*: `a.allocate(n, hint)` if that expression is well-formed; otherwise, `a.allocate(n)`.

```
static constexpr allocation_result<pointer, size_type> allocate_at_least(Alloc& a, size_type n);
```

3 *Returns*: `a.allocate_at_least(n)` if that expression is well-formed; otherwise, `{a.allocate(n), n}`.

```
static constexpr void deallocate(Alloc& a, pointer p, size_type n);
```

4 *Effects*: Calls `a.deallocate(p, n)`.

5 *Throws*: Nothing.

```
template<class T, class... Args>
  static constexpr void construct(Alloc& a, T* p, Args&&... args);
```

6 *Effects*: Calls `a.construct(p, std::forward<Args>(args)...)` if that call is well-formed; otherwise, invokes `construct_at(p, std::forward<Args>(args)...)`.

```
template<class T>
  static constexpr void destroy(Alloc& a, T* p);
```

7 *Effects*: Calls `a.destroy(p)` if that call is well-formed; otherwise, invokes `destroy_at(p)`.

```
static constexpr size_type max_size(const Alloc& a) noexcept;
```

8 *Returns*: `a.max_size()` if that expression is well-formed; otherwise, `numeric_limits<size_type>::max() / sizeof(value_type)`.

```
static constexpr Alloc select_on_container_copy_construction(const Alloc& rhs);
```

9 *Returns*: `rhs.select_on_container_copy_construction()` if that expression is well-formed; otherwise, `rhs`.

20.2.9.4 Other [allocator.traits.other]

1 The class template `allocation_result` has the template parameters, data members, and special members specified above. It has no base classes or members other than those specified.

20.2.10 The default allocator [default.allocator]

20.2.10.1 General [default.allocator.general]

1 All specializations of the default allocator meet the allocator completeness requirements (16.4.4.6.2).

```
namespace std {
  template<class T> class allocator {
  public:
    using value_type                             = T;
    using size_type                              = size_t;
    using difference_type                        = ptrdiff_t;
    using propagate_on_container_move_assignment = true_type;

    constexpr allocator() noexcept;
    constexpr allocator(const allocator&) noexcept;
    template<class U> constexpr allocator(const allocator<U>&) noexcept;
    constexpr ~allocator();
    constexpr allocator& operator=(const allocator&) = default;

    constexpr T* allocate(size_t n);
    constexpr allocation_result<T*> allocate_at_least(size_t n);
    constexpr void deallocate(T* p, size_t n);
  };
}
```

2 `allocator_traits<allocator<T>>::is_always_equal::value` is `true` for any `T`.

20.2.10.2 Members [allocator.members]

1 Except for the destructor, member functions of the default allocator shall not introduce data races (6.10.2) as a result of concurrent calls to those member functions from different threads. Calls to these functions that allocate or deallocate a particular unit of storage shall occur in a single total order, and each such deallocation call shall happen before the next allocation (if any) in this order.

```
constexpr T* allocate(size_t n);
```

2 *Mandates*: `T` is not an incomplete type (6.9.1).

3 *Returns*: A pointer to the initial element of an array of `n T`.

4 *Throws*: `bad_array_new_length` if `numeric_limits<size_t>::max() / sizeof(T) < n`, or `bad_alloc` if the storage cannot be obtained.

5 *Remarks*: The storage for the array is obtained by calling `::operator new` (17.6.3), but it is unspecified when or how often this function is called. This function starts the lifetime of the array object, but not that of any of the array elements.

```
constexpr allocation_result<T*> allocate_at_least(size_t n);
```

6 *Mandates*: `T` is not an incomplete type (6.9.1).

7 *Returns*: `allocation_result<T*>{ptr, count}`, where `ptr` is a pointer to the initial element of an array of `count T` and `count` $\geq$ `n`.

8 *Throws*: `bad_array_new_length` if `numeric_limits<size_t>::max() / sizeof(T)` $<$ `n`, or `bad_alloc` if the storage cannot be obtained.

9 *Remarks*: The storage for the array is obtained by calling `::operator new`, but it is unspecified when or how often this function is called. This function starts the lifetime of the array object, but not that of any of the array elements.

```
constexpr void deallocate(T* p, size_t n);
```

10 *Preconditions*:

(10.1) — If `p` is memory that was obtained by a call to `allocate_at_least`, let `ret` be the value returned and `req` be the value passed as the first argument to that call. `p` is equal to `ret.ptr` and `n` is a value such that `req` $\leq$ `n` $\leq$ `ret.count`.

(10.2) — Otherwise, `p` is a pointer value obtained from `allocate`. `n` equals the value passed as the first argument to the invocation of `allocate` which returned `p`.

11 *Effects*: Deallocates the storage referenced by `p`.

12 *Remarks*: Uses `::operator delete` (17.6.3), but it is unspecified when this function is called.

20.2.10.3 Operators [allocator.globals]

```
template<class T, class U>
  constexpr bool operator==(const allocator<T>&, const allocator<U>&) noexcept;
```

1 *Returns*: `true`.

20.2.11 `addressof` [specialized.addressof]

```
template<class T> constexpr T* addressof(T& r) noexcept;
```

1 *Returns*: The actual address of the object or function referenced by `r`, even in the presence of an overloaded `operator&`.

2 *Remarks*: An expression `addressof(E)` is a constant subexpression (3.15) if `E` is an lvalue constant subexpression.

20.2.12 C library memory allocation [c.malloc]

1 [*Note 1*: The header `<cstdlib>` (17.2.2) declares the functions described in this subclause. — *end note*]

```
void* aligned_alloc(size_t alignment, size_t size);
void* calloc(size_t nmemb, size_t size);
```

```
void* malloc(size_t size);
```

2 *Effects*: These functions have the semantics specified in the C standard library.

3 *Remarks*: These functions do not attempt to allocate storage by calling `::operator new()` (17.6.3).

4 These functions implicitly create objects (6.8.2) in the returned region of storage and return a pointer to a suitable created object. In the case of `calloc`, the objects are created before the storage is zeroed.

```
void* realloc(void* ptr, size_t size);
```

5 *Preconditions*: `free(ptr)` has well-defined behavior.

6 *Effects*: If `ptr` is not null and `size` is zero, the behavior is erroneous and the effects are implementation-defined. Otherwise, this function has the semantics specified in the C standard library.

7 *Remarks*: This function does not attempt to allocate storage by calling `::operator new()` (17.6.3). When a non-null pointer is returned, this function implicitly creates objects (6.8.2) in the returned region of storage and returns a pointer to a suitable created object. The objects are created before the storage is copied.

```
void free(void* ptr);
```

8 *Effects*: This function has the semantics specified in the C standard library.

9 *Remarks*: This function does not attempt to deallocate storage by calling `::operator delete()`.

20.3 Smart pointers [smartptr]

20.3.1 Unique-ownership pointers [unique.ptr]

20.3.1.1 General [unique.ptr.general]

1 A *unique pointer* is an object that owns another object and manages that other object through a pointer. More precisely, a unique pointer is an object u that stores a pointer to a second object p and will dispose of p when u is itself destroyed (e.g., when leaving block scope (8.10)). In this context, u is said to *own* `p`.

2 The mechanism by which u disposes of p is known as p's associated *deleter*, a function object whose correct invocation results in p's appropriate disposition (typically its deletion).

3 Let the notation $u.p$ denote the pointer stored by u, and let $u.d$ denote the associated deleter. Upon request, u can *reset* (replace) $u.p$ and $u.d$ with another pointer and deleter, but properly disposes of its owned object via the associated deleter before such replacement is considered completed.

4 Each object of a type `U` instantiated from the `unique_ptr` template specified in 20.3.1 has the strict ownership semantics, specified above, of a unique pointer. In partial satisfaction of these semantics, each such `U` is *Cpp17MoveConstructible* and *Cpp17MoveAssignable*, but is not *Cpp17CopyConstructible* nor *Cpp17CopyAssignable*. The template parameter `T` of `unique_ptr` may be an incomplete type.

5 [*Note 1*: The uses of `unique_ptr` include providing exception safety for dynamically allocated memory, passing ownership of dynamically allocated memory to a function, and returning dynamically allocated memory from a function. — *end note*]

20.3.1.2 Default deleters [unique.ptr.dltr]

20.3.1.2.1 General [unique.ptr.dltr.general]

1 The class template `default_delete` serves as the default deleter (destruction policy) for the class template `unique_ptr`.

2 The template parameter `T` of `default_delete` may be an incomplete type.

20.3.1.2.2 `default_delete` [unique.ptr.dltr.dflt]

```
namespace std {
  template<class T> struct default_delete {
    constexpr default_delete() noexcept = default;
    template<class U> constexpr default_delete(const default_delete<U>&) noexcept;
    constexpr void operator()(T*) const;
  };
}
```

```
template<class U> constexpr default_delete(const default_delete<U>& other) noexcept;
```

1 *Constraints*: `U*` is implicitly convertible to `T*`.

2 *Effects*: Constructs a `default_delete` object from another `default_delete<U>` object.

```
constexpr void operator()(T* ptr) const;
```

3 *Mandates*: `T` is a complete type.

4 *Effects*: Calls `delete` on `ptr`.

20.3.1.2.3 `default_delete<T[]>` [unique.ptr.dltr.dflt1]

```
namespace std {
  template<class T> struct default_delete<T[]> {
    constexpr default_delete() noexcept = default;
    template<class U> constexpr default_delete(const default_delete<U[]>&) noexcept;
    template<class U> constexpr void operator()(U* ptr) const;
  };
}
```

```
template<class U> constexpr default_delete(const default_delete<U[]>& other) noexcept;
```

1 *Constraints*: `U(*)[]` is convertible to `T(*)[]`.

2 *Effects*: Constructs a `default_delete` object from another `default_delete<U[]>` object.

```
template<class U> constexpr void operator()(U* ptr) const;
```

3 *Constraints*: `U(*)[]` is convertible to `T(*)[]`.

4 *Mandates*: `U` is a complete type.

5 *Effects*: Calls `delete[]` on `ptr`.

20.3.1.3 `unique_ptr` for single objects [unique.ptr.single]

20.3.1.3.1 General [unique.ptr.single.general]

```
namespace std {
  template<class T, class D = default_delete<T>> class unique_ptr {
  public:
    using pointer      = see below;
    using element_type = T;
    using deleter_type = D;

    // 20.3.1.3.2, constructors
    constexpr unique_ptr() noexcept;
    constexpr explicit unique_ptr(type_identity_t<pointer> p) noexcept;
    constexpr unique_ptr(type_identity_t<pointer> p, see below d1) noexcept;
    constexpr unique_ptr(type_identity_t<pointer> p, see below d2) noexcept;
    constexpr unique_ptr(unique_ptr&& u) noexcept;
    constexpr unique_ptr(nullptr_t) noexcept;
    template<class U, class E>
      constexpr unique_ptr(unique_ptr<U, E>&& u) noexcept;

    // 20.3.1.3.3, destructor
    constexpr ~unique_ptr();

    // 20.3.1.3.4, assignment
    constexpr unique_ptr& operator=(unique_ptr&& u) noexcept;
    template<class U, class E>
      constexpr unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
    constexpr unique_ptr& operator=(nullptr_t) noexcept;

    // 20.3.1.3.5, observers
    constexpr add_lvalue_reference_t<T> operator*() const noexcept(see below);
    constexpr pointer operator->() const noexcept;
    constexpr pointer get() const noexcept;
    constexpr deleter_type& get_deleter() noexcept;
```

```
    constexpr const deleter_type& get_deleter() const noexcept;
    constexpr explicit operator bool() const noexcept;

    // 20.3.1.3.6, modifiers
    constexpr pointer release() noexcept;
    constexpr void reset(pointer p = pointer()) noexcept;
    constexpr void swap(unique_ptr& u) noexcept;

    // disable copy from lvalue
    unique_ptr(const unique_ptr&) = delete;
    unique_ptr& operator=(const unique_ptr&) = delete;
  };
}
```

1 A program that instantiates the definition of `unique_ptr<T, D>` is ill-formed if `T*` is an invalid type.

[*Note 1*: This prevents the instantiation of specializations such as `unique_ptr<T&, D>` and `unique_ptr<int() const, D>`. — *end note*]

2 The default type for the template parameter `D` is `default_delete`. A client-supplied template argument `D` shall be a function object type (22.10), lvalue reference to function, or lvalue reference to function object type for which, given a value `d` of type `D` and a value `ptr` of type `unique_ptr<T, D>::pointer`, the expression `d(ptr)` is valid and has the effect of disposing of the pointer as appropriate for that deleter.

3 If the deleter's type `D` is not a reference type, `D` shall meet the *Cpp17Destructible* requirements (Table 35).

4 If the *qualified-id* `remove_reference_t<D>::pointer` is valid and denotes a type (13.10.3), then `unique_ptr<T, D>::pointer` shall be a synonym for `remove_reference_t<D>::pointer`. Otherwise `unique_ptr<T, D>::pointer` shall be a synonym for `element_type*`. The type `unique_ptr<T, D>::pointer` shall meet the *Cpp17NullablePointer* requirements (Table 36).

5 [*Example 1*: Given an allocator type `X` (16.4.4.6.1) and letting `A` be a synonym for `allocator_traits<X>`, the types `A::pointer`, `A::const_pointer`, `A::void_pointer`, and `A::const_void_pointer` may be used as `unique_ptr<T, D>::pointer`. — *end example*]

20.3.1.3.2 Constructors [unique.ptr.single.ctor]

```
constexpr unique_ptr() noexcept;
constexpr unique_ptr(nullptr_t) noexcept;
```

1 *Constraints*: `is_pointer_v<deleter_type>` is `false` and `is_default_constructible_v<deleter_type>` is `true`.

2 *Preconditions*: `D` meets the *Cpp17DefaultConstructible* requirements (Table 30), and that construction does not throw an exception.

3 *Effects*: Constructs a `unique_ptr` object that owns nothing, value-initializing the stored pointer and the stored deleter.

4 *Postconditions*: `get() == nullptr`. `get_deleter()` returns a reference to the stored deleter.

```
constexpr explicit unique_ptr(type_identity_t<pointer> p) noexcept;
```

5 *Constraints*: `is_pointer_v<deleter_type>` is `false` and `is_default_constructible_v<deleter_type>` is `true`.

6 *Preconditions*: `D` meets the *Cpp17DefaultConstructible* requirements (Table 30), and that construction does not throw an exception.

7 *Effects*: Constructs a `unique_ptr` which owns `p`, initializing the stored pointer with `p` and value-initializing the stored deleter.

8 *Postconditions*: `get() == p`. `get_deleter()` returns a reference to the stored deleter.

```
constexpr unique_ptr(type_identity_t<pointer> p, const D& d) noexcept;
constexpr unique_ptr(type_identity_t<pointer> p, remove_reference_t<D>&& d) noexcept;
```

9 *Constraints*: `is_constructible_v<D, decltype(d)>` is `true`.

10 *Preconditions*: For the first constructor, if `D` is not a reference type, `D` meets the *Cpp17CopyConstructible* requirements and such construction does not exit via an exception. For the second constructor, if `D` is

not a reference type, `D` meets the *Cpp17MoveConstructible* requirements and such construction does not exit via an exception.

11 *Effects*: Constructs a `unique_ptr` object which owns `p`, initializing the stored pointer with `p` and initializing the deleter from `std::forward<decltype(d)>(d)`.

12 *Postconditions*: `get() == p`. `get_deleter()` returns a reference to the stored deleter. If `D` is a reference type then `get_deleter()` returns a reference to the lvalue `d`.

13 *Remarks*: If `D` is a reference type, the second constructor is defined as deleted.

14 [*Example 1*:

```
D d;
unique_ptr<int, D> p1(new int, D());         // D must be Cpp17MoveConstructible
unique_ptr<int, D> p2(new int, d);           // D must be Cpp17CopyConstructible
unique_ptr<int, D&> p3(new int, d);          // p3 holds a reference to d
unique_ptr<int, const D&> p4(new int, D()); // error: rvalue deleter object combined
                                             // with reference deleter type
```

— *end example*]

```
constexpr unique_ptr(unique_ptr&& u) noexcept;
```

15 *Constraints*: `is_move_constructible_v<D>` is `true`.

16 *Preconditions*: If `D` is not a reference type, `D` meets the *Cpp17MoveConstructible* requirements (Table 31). Construction of the deleter from an rvalue of type `D` does not throw an exception.

17 *Effects*: Constructs a `unique_ptr` from `u`. If `D` is a reference type, this deleter is copy constructed from `u`'s deleter; otherwise, this deleter is move constructed from `u`'s deleter.

[*Note 1*: The construction of the deleter can be implemented with `std::forward<D>`. — *end note*]

18 *Postconditions*: `get()` yields the value `u.get()` yielded before the construction. `u.get() == nullptr`. `get_deleter()` returns a reference to the stored deleter that was constructed from `u.get_deleter()`. If `D` is a reference type then `get_deleter()` and `u.get_deleter()` both reference the same lvalue deleter.

```
template<class U, class E> constexpr unique_ptr(unique_ptr<U, E>&& u) noexcept;
```

19 *Constraints*:

(19.1) — `unique_ptr<U, E>::pointer` is implicitly convertible to `pointer`,

(19.2) — `U` is not an array type, and

(19.3) — either `D` is a reference type and `E` is the same type as `D`, or `D` is not a reference type and `E` is implicitly convertible to `D`.

20 *Preconditions*: If `E` is not a reference type, construction of the deleter from an rvalue of type `E` is well-formed and does not throw an exception. Otherwise, `E` is a reference type and construction of the deleter from an lvalue of type `E` is well-formed and does not throw an exception.

21 *Effects*: Constructs a `unique_ptr` from `u`. If `E` is a reference type, this deleter is copy constructed from `u`'s deleter; otherwise, this deleter is move constructed from `u`'s deleter.

[*Note 2*: The deleter constructor can be implemented with `std::forward<E>`. — *end note*]

22 *Postconditions*: `get()` yields the value `u.get()` yielded before the construction. `u.get() == nullptr`. `get_deleter()` returns a reference to the stored deleter that was constructed from `u.get_deleter()`.

20.3.1.3.3 Destructor [unique.ptr.single.dtor]

```
constexpr ~unique_ptr();
```

1 *Effects*: Equivalent to: `if (get()) get_deleter()(get());`

[*Note 1*: The use of `default_delete` requires `T` to be a complete type. — *end note*]

2 *Remarks*: The behavior is undefined if the evaluation of `get_deleter()(get())` throws an exception.

20.3.1.3.4 Assignment [unique.ptr.single.asgn]

```
constexpr unique_ptr& operator=(unique_ptr&& u) noexcept;
```

1 *Constraints*: `is_move_assignable_v<D>` is `true`.

2 *Preconditions*: If `D` is not a reference type, `D` meets the *Cpp17MoveAssignable* requirements (Table 33) and assignment of the deleter from an rvalue of type `D` does not throw an exception. Otherwise, `D` is a reference type; `remove_reference_t<D>` meets the *Cpp17CopyAssignable* requirements and assignment of the deleter from an lvalue of type `D` does not throw an exception.

3 *Effects*: Calls `reset(u.release())` followed by `get_deleter() = std::forward<D>(u.get_deleter())`.

4 *Postconditions*: If `this != addressof(u)`, `u.get() == nullptr`, otherwise `u.get()` is unchanged.

5 *Returns*: `*this`.

```
template<class U, class E> constexpr unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
```

6 *Constraints*:

(6.1) — `unique_ptr<U, E>::pointer` is implicitly convertible to `pointer`, and

(6.2) — `U` is not an array type, and

(6.3) — `is_assignable_v<D&, E&&>` is `true`.

7 *Preconditions*: If `E` is not a reference type, assignment of the deleter from an rvalue of type `E` is well-formed and does not throw an exception. Otherwise, `E` is a reference type and assignment of the deleter from an lvalue of type `E` is well-formed and does not throw an exception.

8 *Effects*: Calls `reset(u.release())` followed by `get_deleter() = std::forward<E>(u.get_deleter())`.

9 *Postconditions*: `u.get() == nullptr`.

10 *Returns*: `*this`.

```
constexpr unique_ptr& operator=(nullptr_t) noexcept;
```

11 *Effects*: As if by `reset()`.

12 *Postconditions*: `get() == nullptr`.

13 *Returns*: `*this`.

20.3.1.3.5 Observers [unique.ptr.single.observers]

```
constexpr add_lvalue_reference_t<T> operator*() const noexcept(noexcept(*declval<pointer>()));
```

1 *Constraints*: `*declval<pointer>()` is a well-formed expression.

2 *Mandates*: `reference_converts_from_temporary_v<add_lvalue_reference_t<T>, decltype(*declval<pointer>())>` is `false`.

3 *Preconditions*: `get() != nullptr` is `true`.

4 *Returns*: `*get()`.

```
constexpr pointer operator->() const noexcept;
```

5 *Preconditions*: `get() != nullptr`.

6 *Returns*: `get()`.

7 [*Note 1*: The use of this function typically requires that `T` be a complete type. — *end note*]

```
constexpr pointer get() const noexcept;
```

8 *Returns*: The stored pointer.

```
constexpr deleter_type& get_deleter() noexcept;
constexpr const deleter_type& get_deleter() const noexcept;
```

9 *Returns*: A reference to the stored deleter.

```
constexpr explicit operator bool() const noexcept;
```

10 *Returns*: `get() != nullptr`.

20.3.1.3.6 Modifiers [unique.ptr.single.modifiers]

```
constexpr pointer release() noexcept;
```

1 *Postconditions*: `get() == nullptr`.

2 *Returns*: The value `get()` had at the start of the call to `release`.

```
constexpr void reset(pointer p = pointer()) noexcept;
```

3 *Effects*: Assigns `p` to the stored pointer, and then, with the old value of the stored pointer, `old_p`, evaluates `if (old_p) get_deleter()(old_p);`

[*Note 1*: The order of these operations is significant because the call to `get_deleter()` might destroy `*this`. — *end note*]

4 *Postconditions*: `get() == p`.

[*Note 2*: The postcondition does not hold if the call to `get_deleter()` destroys `*this` since `this->get()` is no longer a valid expression. — *end note*]

5 *Remarks*: The behavior is undefined if the evaluation of `get_deleter()(old_p)` throws an exception.

```
constexpr void swap(unique_ptr& u) noexcept;
```

6 *Preconditions*: `get_deleter()` is swappable (16.4.4.3) and does not throw an exception under `swap`.

7 *Effects*: Invokes `swap` on the stored pointers and on the stored deleters of `*this` and `u`.

20.3.1.4 unique_ptr for array objects with a runtime length [unique.ptr.runtime]

20.3.1.4.1 General [unique.ptr.runtime.general]

```
namespace std {
  template<class T, class D> class unique_ptr<T[], D> {
  public:
    using pointer      = see below;
    using element_type = T;
    using deleter_type = D;

    // 20.3.1.4.2, constructors
    constexpr unique_ptr() noexcept;
    template<class U> constexpr explicit unique_ptr(U p) noexcept;
    template<class U> constexpr unique_ptr(U p, see below d) noexcept;
    template<class U> constexpr unique_ptr(U p, see below d) noexcept;
    constexpr unique_ptr(unique_ptr&& u) noexcept;
    template<class U, class E>
      constexpr unique_ptr(unique_ptr<U, E>&& u) noexcept;
    constexpr unique_ptr(nullptr_t) noexcept;

    // destructor
    constexpr ~unique_ptr();

    // assignment
    constexpr unique_ptr& operator=(unique_ptr&& u) noexcept;
    template<class U, class E>
      constexpr unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
    constexpr unique_ptr& operator=(nullptr_t) noexcept;

    // 20.3.1.4.4, observers
    constexpr T& operator[](size_t i) const;
    constexpr pointer get() const noexcept;
    constexpr deleter_type& get_deleter() noexcept;
    constexpr const deleter_type& get_deleter() const noexcept;
    constexpr explicit operator bool() const noexcept;
```

```
    // 20.3.1.4.5, modifiers
    constexpr pointer release() noexcept;
    template<class U> constexpr void reset(U p) noexcept;
    constexpr void reset(nullptr_t = nullptr) noexcept;
    constexpr void swap(unique_ptr& u) noexcept;

    // disable copy from lvalue
    unique_ptr(const unique_ptr&) = delete;
    unique_ptr& operator=(const unique_ptr&) = delete;
  };
}
```

1 A specialization for array types is provided with a slightly altered interface.

(1.1) — Conversions between different types of `unique_ptr<T[], D>` that would be disallowed for the corresponding pointer-to-array types, and conversions to or from the non-array forms of `unique_ptr`, produce an ill-formed program.

(1.2) — Pointers to types derived from `T` are rejected by the constructors, and by `reset`.

(1.3) — The observers `operator*` and `operator->` are not provided.

(1.4) — The indexing observer `operator[]` is provided.

(1.5) — The default deleter will call `delete[]`.

2 Descriptions are provided below only for members that differ from the primary template.

3 The template argument `T` shall be a complete type.

20.3.1.4.2 Constructors [unique.ptr.runtime.ctor]

```
template<class U> constexpr explicit unique_ptr(U p) noexcept;
```

1 This constructor behaves the same as the constructor in the primary template that takes a single parameter of type `pointer`.

2 *Constraints*:

(2.1) — `U` is the same type as `pointer`, or

(2.2) — `pointer` is the same type as `element_type*`, `U` is a pointer type `V*`, and `V(*)[]` is convertible to `element_type(*)[]`.

```
template<class U> constexpr unique_ptr(U p, see below d) noexcept;
template<class U> constexpr unique_ptr(U p, see below d) noexcept;
```

3 These constructors behave the same as the constructors in the primary template that take a parameter of type `pointer` and a second parameter.

4 *Constraints*:

(4.1) — `U` is the same type as `pointer`,

(4.2) — `U` is `nullptr_t`, or

(4.3) — `pointer` is the same type as `element_type*`, `U` is a pointer type `V*`, and `V(*)[]` is convertible to `element_type(*)[]`.

```
template<class U, class E> constexpr unique_ptr(unique_ptr<U, E>&& u) noexcept;
```

5 This constructor behaves the same as in the primary template.

6 *Constraints*: Where `UP` is `unique_ptr<U, E>`:

(6.1) — `U` is an array type, and

(6.2) — `pointer` is the same type as `element_type*`, and

(6.3) — `UP::pointer` is the same type as `UP::element_type*`, and

(6.4) — `UP::element_type(*)[]` is convertible to `element_type(*)[]`, and

(6.5) — either `D` is a reference type and `E` is the same type as `D`, or `D` is not a reference type and `E` is implicitly convertible to `D`.

[*Note 1*: This replaces the *Constraints*: specification of the primary template. — *end note*]

20.3.1.4.3 Assignment [unique.ptr.runtime.asgn]

```
template<class U, class E> constexpr unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
```

1 This operator behaves the same as in the primary template.

2 *Constraints*: Where `UP` is `unique_ptr<U, E>`:

(2.1) — `U` is an array type, and

(2.2) — `pointer` is the same type as `element_type*`, and

(2.3) — `UP::pointer` is the same type as `UP::element_type*`, and

(2.4) — `UP::element_type(*)[]` is convertible to `element_type(*)[]`, and

(2.5) — `is_assignable_v<D&, E&&>` is `true`.

[*Note 1*: This replaces the *Constraints*: specification of the primary template. — *end note*]

20.3.1.4.4 Observers [unique.ptr.runtime.observers]

```
constexpr T& operator[](size_t i) const;
```

1 *Preconditions*: `i` < the number of elements in the array to which the stored pointer points.

2 *Returns*: `get()[i]`.

20.3.1.4.5 Modifiers [unique.ptr.runtime.modifiers]

```
constexpr void reset(nullptr_t p = nullptr) noexcept;
```

1 *Effects*: Equivalent to `reset(pointer())`.

```
template<class U> constexpr void reset(U p) noexcept;
```

2 This function behaves the same as the `reset` member of the primary template.

3 *Constraints*:

(3.1) — `U` is the same type as `pointer`, or

(3.2) — `pointer` is the same type as `element_type*`, `U` is a pointer type `V*`, and `V(*)[]` is convertible to `element_type(*)[]`.

20.3.1.5 Creation [unique.ptr.create]

```
template<class T, class... Args> constexpr unique_ptr<T> make_unique(Args&&... args);
```

1 *Constraints*: `T` is not an array type.

2 *Returns*: `unique_ptr<T>(new T(std::forward<Args>(args)...))`.

```
template<class T> constexpr unique_ptr<T> make_unique(size_t n);
```

3 *Constraints*: `T` is an array of unknown bound.

4 *Returns*: `unique_ptr<T>(new remove_extent_t<T>[n]())`.

```
template<class T, class... Args> unspecified make_unique(Args&&...) = delete;
```

5 *Constraints*: `T` is an array of known bound.

```
template<class T> constexpr unique_ptr<T> make_unique_for_overwrite();
```

6 *Constraints*: `T` is not an array type.

7 *Returns*: `unique_ptr<T>(new T)`.

```
template<class T> constexpr unique_ptr<T> make_unique_for_overwrite(size_t n);
```

8 *Constraints*: `T` is an array of unknown bound.

9 *Returns*: `unique_ptr<T>(new remove_extent_t<T>[n])`.

```
template<class T, class... Args> unspecified make_unique_for_overwrite(Args&&...) = delete;
```

10 *Constraints*: `T` is an array of known bound.

20.3.1.6 Specialized algorithms [unique.ptr.special]

```
template<class T, class D> constexpr void swap(unique_ptr<T, D>& x, unique_ptr<T, D>& y) noexcept;
```

1 *Constraints*: `is_swappable_v<D>` is `true`.

2 *Effects*: Calls `x.swap(y)`.

```
template<class T1, class D1, class T2, class D2>
  constexpr bool operator==(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

3 *Returns*: `x.get() == y.get()`.

```
template<class T1, class D1, class T2, class D2>
  constexpr bool operator<(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

4 Let `CT` denote

```
common_type_t<typename unique_ptr<T1, D1>::pointer,
              typename unique_ptr<T2, D2>::pointer>
```

5 *Mandates*:

(5.1) — `unique_ptr<T1, D1>::pointer` is implicitly convertible to `CT` and

(5.2) — `unique_ptr<T2, D2>::pointer` is implicitly convertible to `CT`.

6 *Preconditions*: The specialization `less<CT>` is a function object type (22.10) that induces a strict weak ordering (26.8) on the pointer values.

7 *Returns*: `less<CT>()(x.get(), y.get())`.

```
template<class T1, class D1, class T2, class D2>
  constexpr bool operator>(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

8 *Returns*: `y < x`.

```
template<class T1, class D1, class T2, class D2>
  constexpr bool operator<=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

9 *Returns*: `!(y < x)`.

```
template<class T1, class D1, class T2, class D2>
  constexpr bool operator>=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

10 *Returns*: `!(x < y)`.

```
template<class T1, class D1, class T2, class D2>
  requires three_way_comparable_with<typename unique_ptr<T1, D1>::pointer,
                                     typename unique_ptr<T2, D2>::pointer>
  constexpr compare_three_way_result_t<typename unique_ptr<T1, D1>::pointer,
                                       typename unique_ptr<T2, D2>::pointer>
    operator<=>(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

11 *Returns*: `compare_three_way()(x.get(), y.get())`.

```
template<class T, class D>
  constexpr bool operator==(const unique_ptr<T, D>& x, nullptr_t) noexcept;
```

12 *Returns*: `!x`.

```
template<class T, class D>
  constexpr bool operator<(const unique_ptr<T, D>& x, nullptr_t);
template<class T, class D>
  constexpr bool operator<(nullptr_t, const unique_ptr<T, D>& x);
```

13 *Preconditions*: The specialization `less<unique_ptr<T, D>::pointer>` is a function object type (22.10) that induces a strict weak ordering (26.8) on the pointer values.

14 *Returns*: The first function template returns

```
less<unique_ptr<T, D>::pointer>()(x.get(), nullptr)
```

The second function template returns

```
less<unique_ptr<T, D>::pointer>()(nullptr, x.get())
```

```
template<class T, class D>
  constexpr bool operator>(const unique_ptr<T, D>& x, nullptr_t);
template<class T, class D>
  constexpr bool operator>(nullptr_t, const unique_ptr<T, D>& x);
```

15 *Returns*: The first function template returns `nullptr < x`. The second function template returns `x < nullptr`.

```
template<class T, class D>
  constexpr bool operator<=(const unique_ptr<T, D>& x, nullptr_t);
template<class T, class D>
  constexpr bool operator<=(nullptr_t, const unique_ptr<T, D>& x);
```

16 *Returns*: The first function template returns `!(nullptr < x)`. The second function template returns `!(x < nullptr)`.

```
template<class T, class D>
  constexpr bool operator>=(const unique_ptr<T, D>& x, nullptr_t);
template<class T, class D>
  constexpr bool operator>=(nullptr_t, const unique_ptr<T, D>& x);
```

17 *Returns*: The first function template returns `!(x < nullptr)`. The second function template returns `!(nullptr < x)`.

```
template<class T, class D>
  requires three_way_comparable<typename unique_ptr<T, D>::pointer>
  constexpr compare_three_way_result_t<typename unique_ptr<T, D>::pointer>
    operator<=>(const unique_ptr<T, D>& x, nullptr_t);
```

18 *Returns*:

```
compare_three_way()(x.get(), static_cast<typename unique_ptr<T, D>::pointer>(nullptr)).
```

20.3.1.7 I/O [unique.ptr.io]

```
template<class E, class T, class Y, class D>
  basic_ostream<E, T>& operator<<(basic_ostream<E, T>& os, const unique_ptr<Y, D>& p);
```

1 *Constraints*: `os << p.get()` is a valid expression.

2 *Effects*: Equivalent to: `os << p.get();`

3 *Returns*: `os`.

20.3.2 Shared-ownership pointers [util.sharedptr]

20.3.2.1 Class `bad_weak_ptr` [util.smartptr.weak.bad]

```
namespace std {
  class bad_weak_ptr : public exception {
  public:
    // see 17.9.3 for the specification of the special member functions
    constexpr const char* what() const noexcept override;
  };
}
```

1 An exception of type `bad_weak_ptr` is thrown by the `shared_ptr` constructor taking a `weak_ptr`.

```
constexpr const char* what() const noexcept override;
```

2 *Returns*: An implementation-defined NTBS.

20.3.2.2 Class template `shared_ptr` [util.smartptr.shared]

20.3.2.2.1 General [util.smartptr.shared.general]

1 The `shared_ptr` class template stores a pointer, usually obtained via `new`. `shared_ptr` implements semantics of shared ownership; the last remaining owner of the pointer is responsible for destroying the object, or otherwise releasing the resources associated with the stored pointer. A `shared_ptr` is said to be empty if it does not own a pointer.

```
namespace std {
  template<class T> class shared_ptr {
  public:
    using element_type = remove_extent_t<T>;
    using weak_type    = weak_ptr<T>;

    // 20.3.2.2.2, constructors
    constexpr shared_ptr() noexcept;
    constexpr shared_ptr(nullptr_t) noexcept : shared_ptr() { }
    template<class Y>
      constexpr explicit shared_ptr(Y* p);
    template<class Y, class D>
      constexpr shared_ptr(Y* p, D d);
    template<class Y, class D, class A>
      constexpr shared_ptr(Y* p, D d, A a);
    template<class D>
      constexpr shared_ptr(nullptr_t p, D d);
    template<class D, class A>
      constexpr shared_ptr(nullptr_t p, D d, A a);
    template<class Y>
      constexpr shared_ptr(const shared_ptr<Y>& r, element_type* p) noexcept;
    template<class Y>
      constexpr shared_ptr(shared_ptr<Y>&& r, element_type* p) noexcept;
    constexpr shared_ptr(const shared_ptr& r) noexcept;
    template<class Y>
      constexpr shared_ptr(const shared_ptr<Y>& r) noexcept;
    constexpr shared_ptr(shared_ptr&& r) noexcept;
    template<class Y>
      constexpr shared_ptr(shared_ptr<Y>&& r) noexcept;
    template<class Y>
      constexpr explicit shared_ptr(const weak_ptr<Y>& r);
    template<class Y, class D>
      constexpr shared_ptr(unique_ptr<Y, D>&& r);

    // 20.3.2.2.3, destructor
    constexpr ~shared_ptr();

    // 20.3.2.2.4, assignment
    constexpr shared_ptr& operator=(const shared_ptr& r) noexcept;
    template<class Y>
      constexpr shared_ptr& operator=(const shared_ptr<Y>& r) noexcept;
    constexpr shared_ptr& operator=(shared_ptr&& r) noexcept;
    template<class Y>
      constexpr shared_ptr& operator=(shared_ptr<Y>&& r) noexcept;
    template<class Y, class D>
      constexpr shared_ptr& operator=(unique_ptr<Y, D>&& r);

    // 20.3.2.2.5, modifiers
    constexpr void swap(shared_ptr& r) noexcept;
    constexpr void reset() noexcept;
    template<class Y>
      constexpr void reset(Y* p);
    template<class Y, class D>
      constexpr void reset(Y* p, D d);
    template<class Y, class D, class A>
      constexpr void reset(Y* p, D d, A a);

    // 20.3.2.2.6, observers
    constexpr element_type* get() const noexcept;
    constexpr T& operator*() const noexcept;
    constexpr T* operator->() const noexcept;
    constexpr element_type& operator[](ptrdiff_t i) const;
    constexpr long use_count() const noexcept;
    constexpr explicit operator bool() const noexcept;
```

```
    template<class U>
      bool owner_before(const shared_ptr<U>& b) const noexcept;
    template<class U>
      bool owner_before(const weak_ptr<U>& b) const noexcept;
    size_t owner_hash() const noexcept;
    template<class U>
      constexpr bool owner_equal(const shared_ptr<U>& b) const noexcept;
    template<class U>
      constexpr bool owner_equal(const weak_ptr<U>& b) const noexcept;
  };

  template<class T>
    shared_ptr(weak_ptr<T>) -> shared_ptr<T>;
  template<class T, class D>
    shared_ptr(unique_ptr<T, D>) -> shared_ptr<T>;
}
```

2 Specializations of `shared_ptr` shall be *Cpp17CopyConstructible*, *Cpp17CopyAssignable*, and *Cpp17LessThanComparable*, allowing their use in standard containers. Specializations of `shared_ptr` shall be contextually convertible to `bool`, allowing their use in boolean expressions and declarations in conditions.

3 The template parameter `T` of `shared_ptr` may be an incomplete type.

[*Note 1*: `T` can be a function type. — *end note*]

4 [*Example 1*:

```
if (shared_ptr<X> px = dynamic_pointer_cast<X>(py)) {
  // do something with px
}
```

— *end example*]

5 For purposes of determining the presence of a data race, member functions shall access and modify only the `shared_ptr` and `weak_ptr` objects themselves and not objects they refer to. Changes in `use_count()` do not reflect modifications that can introduce data races.

6 For the purposes of 20.3, a pointer type `Y*` is said to be *compatible with* a pointer type `T*` when either `Y*` is convertible to `T*` or `Y` is `U[N]` and `T` is *cv* `U[]`.

20.3.2.2.2 Constructors [util.smartptr.shared.const]

1 In the constructor definitions below, enables `shared_from_this` with `p`, for a pointer `p` of type `Y*`, means that if `Y` has an unambiguous and accessible base class that is a specialization of `enable_shared_from_this` (20.3.2.7), then `remove_cv_t<Y>*` shall be implicitly convertible to `T*` and the constructor evaluates the statement:

```
if (p != nullptr && p->weak-this.expired())
  p->weak-this = shared_ptr<remove_cv_t<Y>>(*this, const_cast<remove_cv_t<Y>*>(p));
```

The assignment to the *`weak-this`* member is not atomic and conflicts with any potentially concurrent access to the same object (6.10.2).

```
constexpr shared_ptr() noexcept;
```

2 *Postconditions*: `use_count() == 0 && get() == nullptr`.

```
template<class Y> constexpr explicit shared_ptr(Y* p);
```

3 *Constraints*: When `T` is an array type, the expression `delete[] p` is well-formed and either `T` is `U[N]` and `Y(*)[N]` is convertible to `T*`, or `T` is `U[]` and `Y(*)[]` is convertible to `T*`. When `T` is not an array type, the expression `delete p` is well-formed and `Y*` is convertible to `T*`.

4 *Mandates*: `Y` is a complete type.

5 *Preconditions*: The expression `delete[] p`, when `T` is an array type, or `delete p`, when `T` is not an array type, has well-defined behavior, and does not throw exceptions.

6 *Effects*: When `T` is not an array type, constructs a `shared_ptr` object that owns the pointer `p`. Otherwise, constructs a `shared_ptr` that owns `p` and a deleter of an unspecified type that calls `delete[] p`. When `T` is not an array type, enables `shared_from_this` with `p`. If an exception is thrown, `delete p` is called when `T` is not an array type, `delete[] p` otherwise.

7 *Postconditions*: `use_count() == 1 && get() == p`.

8 *Throws*: `bad_alloc`, or an implementation-defined exception when a resource other than memory cannot be obtained.

```
template<class Y, class D> constexpr shared_ptr(Y* p, D d);
template<class Y, class D, class A> constexpr shared_ptr(Y* p, D d, A a);
template<class D> constexpr shared_ptr(nullptr_t p, D d);
template<class D, class A> constexpr shared_ptr(nullptr_t p, D d, A a);
```

9 *Constraints*: `is_move_constructible_v<D>` is `true`, and `d(p)` is a well-formed expression. For the first two overloads:

(9.1) — If `T` is an array type, then either `T` is `U[N]` and `Y(*)[N]` is convertible to `T*`, or `T` is `U[]` and `Y(*)[]` is convertible to `T*`.

(9.2) — If `T` is not an array type, then `Y*` is convertible to `T*`.

10 *Preconditions*: Construction of `d` and a deleter of type `D` initialized with `std::move(d)` do not throw exceptions. The expression `d(p)` has well-defined behavior and does not throw exceptions. `A` meets the *Cpp17Allocator* requirements (16.4.4.6.1).

11 *Effects*: Constructs a `shared_ptr` object that owns the object `p` and the deleter `d`. When `T` is not an array type, the first and second constructors enable `shared_from_this` with `p`. The second and fourth constructors shall use a copy of `a` to allocate memory for internal use. If an exception is thrown, `d(p)` is called.

12 *Postconditions*: `use_count() == 1 && get() == p`.

13 *Throws*: `bad_alloc`, or an implementation-defined exception when a resource other than memory cannot be obtained.

```
template<class Y> constexpr shared_ptr(const shared_ptr<Y>& r, element_type* p) noexcept;
template<class Y> constexpr shared_ptr(shared_ptr<Y>&& r, element_type* p) noexcept;
```

14 *Effects*: Constructs a `shared_ptr` instance that stores `p` and shares ownership with the initial value of `r`.

15 *Postconditions*: `get() == p`. For the second overload, `r` is empty and `r.get() == nullptr`.

16 [*Note 1*: Use of this constructor leads to a dangling pointer unless `p` remains valid at least until the ownership group of `r` is destroyed. — *end note*]

17 [*Note 2*: This constructor allows creation of an empty `shared_ptr` instance with a non-null stored pointer. — *end note*]

```
constexpr shared_ptr(const shared_ptr& r) noexcept;
template<class Y> constexpr shared_ptr(const shared_ptr<Y>& r) noexcept;
```

18 *Constraints*: For the second constructor, `Y*` is compatible with `T*`.

19 *Effects*: If `r` is empty, constructs an empty `shared_ptr` object; otherwise, constructs a `shared_ptr` object that shares ownership with `r`.

20 *Postconditions*: `get() == r.get() && use_count() == r.use_count()`.

```
constexpr shared_ptr(shared_ptr&& r) noexcept;
template<class Y> constexpr shared_ptr(shared_ptr<Y>&& r) noexcept;
```

21 *Constraints*: For the second constructor, `Y*` is compatible with `T*`.

22 *Effects*: Move constructs a `shared_ptr` instance from `r`.

23 *Postconditions*: `*this` contains the old value of `r`. `r` is empty, and `r.get() == nullptr`.

```
template<class Y> constexpr explicit shared_ptr(const weak_ptr<Y>& r);
```

24 *Constraints*: `Y*` is compatible with `T*`.

25 *Effects*: Constructs a `shared_ptr` object that shares ownership with `r` and stores a copy of the pointer stored in `r`. If an exception is thrown, the constructor has no effect.

26 *Postconditions*: `use_count() == r.use_count()`.

27 *Throws*: `bad_weak_ptr` when `r.expired()`.

```
template<class Y, class D> constexpr shared_ptr(unique_ptr<Y, D>&& r);
```

28 *Constraints*: `Y*` is compatible with `T*` and `unique_ptr<Y, D>::pointer` is convertible to `element_type*`.

29 *Effects*: If `r.get() == nullptr`, equivalent to `shared_ptr()`. Otherwise, if `D` is not a reference type, equivalent to `shared_ptr(r.release(), std::move(r.get_deleter()))`. Otherwise, equivalent to `shared_ptr(r.release(), ref(r.get_deleter()))`. If an exception is thrown, the constructor has no effect.

20.3.2.2.3 Destructor [util.smartptr.shared.dest]

```
constexpr ~shared_ptr();
```

1 *Effects*:

(1.1) — If `*this` is empty or shares ownership with another `shared_ptr` instance (`use_count() > 1`), there are no side effects.

(1.2) — Otherwise, if `*this` owns an object `p` and a deleter `d`, `d(p)` is called.

(1.3) — Otherwise, `*this` owns a pointer `p`, and `delete p` is called.

2 [*Note 1*: Since the destruction of `*this` decreases the number of instances that share ownership with `*this` by one, after `*this` has been destroyed all `shared_ptr` instances that shared ownership with `*this` will report a `use_count()` that is one less than its previous value. — *end note*]

20.3.2.2.4 Assignment [util.smartptr.shared.assign]

```
constexpr shared_ptr& operator=(const shared_ptr& r) noexcept;
template<class Y> constexpr shared_ptr& operator=(const shared_ptr<Y>& r) noexcept;
```

1 *Effects*: Equivalent to `shared_ptr(r).swap(*this)`.

2 *Returns*: `*this`.

3 [*Note 1*: The use count updates caused by the temporary object construction and destruction are not observable side effects, so the implementation can meet the effects (and the implied guarantees) via different means, without creating a temporary. In particular, in the example:

```
shared_ptr<int> p(new int);
shared_ptr<void> q(p);
p = p;
q = p;
```

both assignments can be no-ops. — *end note*]

```
constexpr shared_ptr& operator=(shared_ptr&& r) noexcept;
template<class Y> constexpr shared_ptr& operator=(shared_ptr<Y>&& r) noexcept;
```

4 *Effects*: Equivalent to `shared_ptr(std::move(r)).swap(*this)`.

5 *Returns*: `*this`.

```
template<class Y, class D> constexpr shared_ptr& operator=(unique_ptr<Y, D>&& r);
```

6 *Effects*: Equivalent to `shared_ptr(std::move(r)).swap(*this)`.

7 *Returns*: `*this`.

20.3.2.2.5 Modifiers [util.smartptr.shared.mod]

```
constexpr void swap(shared_ptr& r) noexcept;
```

1 *Effects*: Exchanges the contents of `*this` and `r`.

```
constexpr void reset() noexcept;
```

2 *Effects*: Equivalent to `shared_ptr().swap(*this)`.

```
template<class Y> constexpr void reset(Y* p);
```

3 *Effects*: Equivalent to `shared_ptr(p).swap(*this)`.

```
template<class Y, class D> constexpr void reset(Y* p, D d);
```

4 *Effects*: Equivalent to `shared_ptr(p, d).swap(*this)`.

```
template<class Y, class D, class A> constexpr void reset(Y* p, D d, A a);
```

Effects: Equivalent to `shared_ptr(p, d, a).swap(*this)`.

20.3.2.2.6 Observers [util.smartptr.shared.obs]

```
constexpr element_type* get() const noexcept;
```

Returns: The stored pointer.

```
constexpr T& operator*() const noexcept;
```

Preconditions: `get() != nullptr`.

Returns: `*get()`.

Remarks: When `T` is an array type or *cv* `void`, it is unspecified whether this member function is declared. If it is declared, it is unspecified what its return type is, except that the declaration (although not necessarily the definition) of the function shall be well-formed.

```
constexpr T* operator->() const noexcept;
```

Preconditions: `get() != nullptr`.

Returns: `get()`.

Remarks: When `T` is an array type, it is unspecified whether this member function is declared. If it is declared, it is unspecified what its return type is, except that the declaration (although not necessarily the definition) of the function shall be well-formed.

```
constexpr element_type& operator[](ptrdiff_t i) const;
```

Preconditions: `get() != nullptr` is `true`.

Hardened preconditions: `i` ≥ 0. If `T` is `U[N]`, `i` $<$ `N`.

Returns: `get()[i]`.

Throws: Nothing.

Remarks: When `T` is not an array type, it is unspecified whether this member function is declared. If it is declared, it is unspecified what its return type is, except that the declaration (although not necessarily the definition) of the function shall be well-formed.

```
constexpr long use_count() const noexcept;
```

Synchronization: None.

Returns: The number of `shared_ptr` objects, `*this` included, that share ownership with `*this`, or `0` when `*this` is empty.

[*Note 1*: `get() == nullptr` does not imply a specific return value of `use_count()`. — *end note*]

[*Note 2*: `weak_ptr<T>::lock()` can affect the return value of `use_count()`. — *end note*]

[*Note 3*: When multiple threads might affect the return value of `use_count()`, the result is approximate. In particular, `use_count() == 1` does not imply that accesses through a previously destroyed `shared_ptr` have in any sense completed. — *end note*]

```
constexpr explicit operator bool() const noexcept;
```

Returns: `get() != nullptr`.

```
template<class U> bool owner_before(const shared_ptr<U>& b) const noexcept;
template<class U> bool owner_before(const weak_ptr<U>& b) const noexcept;
```

Returns: An unspecified value such that

(19.1) — `owner_before(b)` defines a strict weak ordering as defined in 26.8;

(19.2) — `!owner_before(b) && !b.owner_before(*this)` is `true` if and only if `owner_equal(b)` is `true`.

```
size_t owner_hash() const noexcept;
```

Returns: An unspecified value such that, for any object `x` where `owner_equal(x)` is `true`, `owner_hash() == x.owner_hash()` is `true`.

```
template<class U>
  constexpr bool owner_equal(const shared_ptr<U>& b) const noexcept;
template<class U>
  constexpr bool owner_equal(const weak_ptr<U>& b) const noexcept;
```

21 *Returns*: `true` if and only if `*this` and `b` share ownership or are both empty. Otherwise returns `false`.

22 *Remarks*: `owner_equal` is an equivalence relation.

20.3.2.2.7 Creation [util.smartptr.shared.create]

1 The common requirements that apply to all `make_shared`, `allocate_shared`, `make_shared_for_overwrite`, and `allocate_shared_for_overwrite` overloads, unless specified otherwise, are described below.

```
template<class T, ...>
  constexpr shared_ptr<T> make_shared(args);
template<class T, class A, ...>
  constexpr shared_ptr<T> allocate_shared(const A& a, args);
template<class T, ...>
  constexpr shared_ptr<T> make_shared_for_overwrite(args);
template<class T, class A, ...>
  constexpr shared_ptr<T> allocate_shared_for_overwrite(const A& a, args);
```

2 *Preconditions*: `A` meets the *Cpp17Allocator* requirements (16.4.4.6.1).

3 *Effects*: Allocates memory for an object of type `T` (or `U[N]` when `T` is `U[]`, where `N` is determined from *args* as specified by the concrete overload). The object is initialized from *args* as specified by the concrete overload. The `allocate_shared` and `allocate_shared_for_overwrite` templates use a copy of `a` (rebound for an unspecified `value_type`) to allocate memory. If an exception is thrown, the functions have no effect.

4 *Postconditions*: `r.get() != nullptr && r.use_count() == 1`, where `r` is the return value.

5 *Returns*: A `shared_ptr` instance that stores and owns the address of the newly constructed object.

6 *Throws*: `bad_alloc`, or an exception thrown from `allocate` or from the initialization of the object.

7 *Remarks*:

(7.1) — Implementations should perform no more than one memory allocation.

[*Note 1*: This provides efficiency equivalent to an intrusive smart pointer. — *end note*]

(7.2) — When an object of an array type `U` is specified to have an initial value of `u` (of the same type), this shall be interpreted to mean that each array element of the object has as its initial value the corresponding element from `u`.

(7.3) — When an object of an array type is specified to have a default initial value, this shall be interpreted to mean that each array element of the object has a default initial value.

(7.4) — When a (sub)object of a non-array type `U` is specified to have an initial value of `v`, or `U(l...)`, where `l...` is a list of constructor arguments, `make_shared` shall initialize this (sub)object via the expression `::new(pv) U(v)` or `::new(pv) U(l...)` respectively, where `pv` has type `void*` and points to storage suitable to hold an object of type `U`.

(7.5) — When a (sub)object of a non-array type `U` is specified to have an initial value of `v`, or `U(l...)`, where `l...` is a list of constructor arguments, `allocate_shared` shall initialize this (sub)object via the expression

(7.5.1) — `allocator_traits<A2>::construct(a2, pu, v)` or

(7.5.2) — `allocator_traits<A2>::construct(a2, pu, l...)`

respectively, where `pu` is a pointer of type `remove_cv_t<U>*` pointing to storage suitable to hold an object of type `remove_cv_t<U>` and `a2` of type `A2` is a potentially rebound copy of the allocator `a` passed to `allocate_shared`.

(7.6) — When a (sub)object of non-array type `U` is specified to have a default initial value, `make_shared` shall initialize this (sub)object via the expression `::new(pv) U()`, where `pv` has type `void*` and points to storage suitable to hold an object of type `U`.

(7.7) — When a (sub)object of non-array type `U` is specified to have a default initial value, `allocate_shared` initializes this (sub)object via the expression `allocator_traits<A2>::construct(a2,`

pu), where pu is a pointer of type remove_cv_t<U>* pointing to storage suitable to hold an object of type remove_cv_t<U> and a2 of type A2 is a potentially rebound copy of the allocator a passed to allocate_shared.

(7.8) — When a (sub)object of non-array type U is initialized by make_shared_for_overwrite or allocate_shared_for_overwrite, it is initialized via the expression ::new(pv) U, where pv has type void* and points to storage suitable to hold an object of type U.

(7.9) — Array elements are initialized in ascending order of their addresses.

(7.10) — When the lifetime of the object managed by the return value ends, or when the initialization of an array element throws an exception, the initialized elements are destroyed in the reverse order of their original construction.

(7.11) — When a (sub)object of non-array type U that was initialized by make_shared, make_shared_for_overwrite, or allocate_shared_for_overwrite is to be destroyed, it is destroyed via the expression pu->~U() where pu points to that object of type U.

(7.12) — When a (sub)object of non-array type U that was initialized by allocate_shared is to be destroyed, it is destroyed via the expression allocator_traits<A2>::destroy(a2, pu) where pu is a pointer of type remove_cv_t<U>* pointing to that object of type remove_cv_t<U> and a2 of type A2 is a potentially rebound copy of the allocator a passed to allocate_shared.

[*Note 2*: These functions will typically allocate more memory than sizeof(T) to allow for internal bookkeeping structures such as reference counts. — *end note*]

```
template<class T, class... Args>
  constexpr shared_ptr<T> make_shared(Args&&... args);                    // T is not array
template<class T, class A, class... Args>
  constexpr shared_ptr<T> allocate_shared(const A& a, Args&&... args);    // T is not array
```

8 *Constraints*: T is not an array type.

9 *Returns*: A shared_ptr to an object of type T with an initial value T(std::forward<Args>(args)...).

10 *Remarks*: The shared_ptr constructors called by these functions enable shared_from_this with the address of the newly constructed object of type T.

11 [*Example 1*:

```
shared_ptr<int> p = make_shared<int>(); // shared_ptr to int()
shared_ptr<vector<int>> q = make_shared<vector<int>>(16, 1);
  // shared_ptr to vector of 16 elements with value 1
```

— *end example*]

```
template<class T>
  constexpr shared_ptr<T> make_shared(size_t N);                          // T is U[]
template<class T, class A>
  constexpr shared_ptr<T> allocate_shared(const A& a, size_t N);          // T is U[]
```

12 *Constraints*: T is an array of unknown bound.

13 *Returns*: A shared_ptr to an array of N elements of type remove_extent_t<T> with a default initial value.

14 [*Example 2*:

```
shared_ptr<double[]> p = make_shared<double[]>(1024);
  // shared_ptr to a value-initialized double[1024]
shared_ptr<double[][2][2]> q = make_shared<double[][2][2]>(6);
  // shared_ptr to a value-initialized double[6][2][2]
```

— *end example*]

```
template<class T>
  constexpr shared_ptr<T> make_shared();                                  // T is U[N]
template<class T, class A>
  constexpr shared_ptr<T> allocate_shared(const A& a);                    // T is U[N]
```

15 *Constraints*: T is an array of known bound.

16 *Returns*: A shared_ptr to an object of type T with a default initial value.

17 [*Example 3*:

```
shared_ptr<double[1024]> p = make_shared<double[1024]>();
  // shared_ptr to a value-initialized double[1024]
shared_ptr<double[6][2][2]> q = make_shared<double[6][2][2]>();
  // shared_ptr to a value-initialized double[6][2][2]
```

— *end example*]

```
template<class T>
  constexpr shared_ptr<T> make_shared(size_t N,
                                      const remove_extent_t<T>& u);     // T is U[]
template<class T, class A>
  constexpr shared_ptr<T> allocate_shared(const A& a, size_t N,
                                          const remove_extent_t<T>& u); // T is U[]
```

18 *Constraints*: `T` is an array of unknown bound.

19 *Returns*: A `shared_ptr` to an array of `N` elements of type `remove_extent_t<T>` where each array element has an initial value of `u`.

20 [*Example 4*:

```
shared_ptr<double[]> p = make_shared<double[]>(1024, 1.0);
  // shared_ptr to a double[1024], where each element is 1.0
shared_ptr<double[][2]> q = make_shared<double[][2]>(6, {1.0, 0.0});
  // shared_ptr to a double[6][2], where each double[2] element is {1.0, 0.0}
shared_ptr<vector<int>[]> r = make_shared<vector<int>[]>(4, {1, 2});
  // shared_ptr to a vector<int>[4], where each vector has contents {1, 2}
```

— *end example*]

```
template<class T>
  constexpr shared_ptr<T> make_shared(const remove_extent_t<T>& u);       // T is U[N]
template<class T, class A>
  constexpr shared_ptr<T> allocate_shared(const A& a,
                                          const remove_extent_t<T>& u);   // T is U[N]
```

21 *Constraints*: `T` is an array of known bound.

22 *Returns*: A `shared_ptr` to an object of type `T`, where each array element of type `remove_extent_t<T>` has an initial value of `u`.

23 [*Example 5*:

```
shared_ptr<double[1024]> p = make_shared<double[1024]>(1.0);
  // shared_ptr to a double[1024], where each element is 1.0
shared_ptr<double[6][2]> q = make_shared<double[6][2]>({1.0, 0.0});
  // shared_ptr to a double[6][2], where each double[2] element is {1.0, 0.0}
shared_ptr<vector<int>[4]> r = make_shared<vector<int>[4]>({1, 2});
  // shared_ptr to a vector<int>[4], where each vector has contents {1, 2}
```

— *end example*]

```
template<class T>
  constexpr shared_ptr<T> make_shared_for_overwrite();
template<class T, class A>
  constexpr shared_ptr<T> allocate_shared_for_overwrite(const A& a);
```

24 *Constraints*: `T` is not an array of unknown bound.

25 *Returns*: A `shared_ptr` to an object of type `T`.

26 [*Example 6*:

```
struct X { double data[1024]; };
shared_ptr<X> p = make_shared_for_overwrite<X>();
  // shared_ptr to a default-initialized X, where each element in X::data has an indeterminate value

shared_ptr<double[1024]> q = make_shared_for_overwrite<double[1024]>();
  // shared_ptr to a default-initialized double[1024], where each element has an indeterminate value
```

— *end example*]

```
template<class T>
  constexpr shared_ptr<T> make_shared_for_overwrite(size_t N);
template<class T, class A>
  constexpr shared_ptr<T> allocate_shared_for_overwrite(const A& a, size_t N);
```

27 *Constraints*: `T` is an array of unknown bound.

28 *Returns*: A `shared_ptr` to an array of `N` elements of type `remove_extent_t<T>`.

29 [*Example 7*:

```
shared_ptr<double[]> p = make_shared_for_overwrite<double[]>(1024);
  // shared_ptr to a default-initialized double[1024], where each element has an indeterminate value
```

— end example]

20.3.2.2.8 Comparison [util.smartptr.shared.cmp]

```
template<class T, class U>
  constexpr bool operator==(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
```

1 *Returns*: `a.get() == b.get()`.

```
template<class T>
  constexpr bool operator==(const shared_ptr<T>& a, nullptr_t) noexcept;
```

2 *Returns*: `!a`.

```
template<class T, class U>
  constexpr strong_ordering operator<=>(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
```

3 *Returns*: `compare_three_way()(a.get(), b.get())`.

4 [*Note 1*: Defining a comparison operator function allows `shared_ptr` objects to be used as keys in associative containers. *— end note*]

```
template<class T>
  constexpr strong_ordering operator<=>(const shared_ptr<T>& a, nullptr_t) noexcept;
```

5 *Returns*:

```
compare_three_way()(a.get(), static_cast<typename shared_ptr<T>::element_type*>(nullptr))
```

20.3.2.2.9 Specialized algorithms [util.smartptr.shared.spec]

```
template<class T>
  constexpr void swap(shared_ptr<T>& a, shared_ptr<T>& b) noexcept;
```

1 *Effects*: Equivalent to `a.swap(b)`.

20.3.2.2.10 Casts [util.smartptr.shared.cast]

```
template<class T, class U>
  constexpr shared_ptr<T> static_pointer_cast(const shared_ptr<U>& r) noexcept;
template<class T, class U>
  constexpr shared_ptr<T> static_pointer_cast(shared_ptr<U>&& r) noexcept;
```

1 *Mandates*: The expression `static_cast<T*>((U*)nullptr)` is well-formed.

2 *Returns*:

```
shared_ptr<T>(R, static_cast<typename shared_ptr<T>::element_type*>(r.get()))
```

where *R* is `r` for the first overload, and `std::move(r)` for the second.

3 [*Note 1*: The seemingly equivalent expression `shared_ptr<T>(static_cast<T*>(r.get()))` can result in undefined behavior, attempting to delete the same object twice. *— end note*]

```
template<class T, class U>
  constexpr shared_ptr<T> dynamic_pointer_cast(const shared_ptr<U>& r) noexcept;
template<class T, class U>
  constexpr shared_ptr<T> dynamic_pointer_cast(shared_ptr<U>&& r) noexcept;
```

4 *Mandates*: The expression `dynamic_cast<T*>((U*)nullptr)` is well-formed. The expression `dynamic_cast<typename shared_ptr<T>::element_type*>(r.get())` is well-formed.

5 *Preconditions*: The expression `dynamic_cast<typename shared_ptr<T>::element_type*>(r.get())` has well-defined behavior.

6 *Returns*:

(6.1) — When `dynamic_cast<typename shared_ptr<T>::element_type*>(r.get())` returns a non-null value `p`, `shared_ptr<T>(`*`R`*`, p)`, where *`R`* is `r` for the first overload, and `std::move(r)` for the second.

(6.2) — Otherwise, `shared_ptr<T>()`.

7 [*Note 2*: The seemingly equivalent expression `shared_ptr<T>(dynamic_cast<T*>(r.get()))` can result in undefined behavior, attempting to delete the same object twice. — *end note*]

```
template<class T, class U>
  constexpr shared_ptr<T> const_pointer_cast(const shared_ptr<U>& r) noexcept;
template<class T, class U>
  constexpr shared_ptr<T> const_pointer_cast(shared_ptr<U>&& r) noexcept;
```

8 *Mandates*: The expression `const_cast<T*>((U*)nullptr)` is well-formed.

9 *Returns*:

```
shared_ptr<T>(R, const_cast<typename shared_ptr<T>::element_type*>(r.get()))
```

where *`R`* is `r` for the first overload, and `std::move(r)` for the second.

10 [*Note 3*: The seemingly equivalent expression `shared_ptr<T>(const_cast<T*>(r.get()))` can result in undefined behavior, attempting to delete the same object twice. — *end note*]

```
template<class T, class U>
  shared_ptr<T> reinterpret_pointer_cast(const shared_ptr<U>& r) noexcept;
template<class T, class U>
  shared_ptr<T> reinterpret_pointer_cast(shared_ptr<U>&& r) noexcept;
```

11 *Mandates*: The expression `reinterpret_cast<T*>((U*)nullptr)` is well-formed.

12 *Returns*:

```
shared_ptr<T>(R, reinterpret_cast<typename shared_ptr<T>::element_type*>(r.get()))
```

where *`R`* is `r` for the first overload, and `std::move(r)` for the second.

13 [*Note 4*: The seemingly equivalent expression `shared_ptr<T>(reinterpret_cast<T*>(r.get()))` can result in undefined behavior, attempting to delete the same object twice. — *end note*]

20.3.2.2.11 `get_deleter` [util.smartptr.getdeleter]

```
template<class D, class T>
  constexpr D* get_deleter(const shared_ptr<T>& p) noexcept;
```

1 *Returns*: If `p` owns a deleter `d` of type cv-unqualified `D`, returns `addressof(d)`; otherwise returns `nullptr`. The returned pointer remains valid as long as there exists a `shared_ptr` instance that owns `d`.

[*Note 1*: It is unspecified whether the pointer remains valid longer than that. This can happen if the implementation doesn't destroy the deleter until all `weak_ptr` instances that share ownership with `p` have been destroyed. — *end note*]

20.3.2.2.12 I/O [util.smartptr.shared.io]

```
template<class E, class T, class Y>
  basic_ostream<E, T>& operator<<(basic_ostream<E, T>& os, const shared_ptr<Y>& p);
```

1 *Effects*: As if by: `os << p.get();`

2 *Returns*: `os`.

20.3.2.3 Class template `weak_ptr` [util.smartptr.weak]

20.3.2.3.1 General [util.smartptr.weak.general]

1 The `weak_ptr` class template stores a weak reference to an object that is already managed by a `shared_ptr`. To access the object, a `weak_ptr` can be converted to a `shared_ptr` using the member function `lock`.

```
namespace std {
  template<class T> class weak_ptr {
  public:
    using element_type = remove_extent_t<T>;

    // 20.3.2.3.2, constructors
    constexpr weak_ptr() noexcept;
    template<class Y>
      constexpr weak_ptr(const shared_ptr<Y>& r) noexcept;
    constexpr weak_ptr(const weak_ptr& r) noexcept;
    template<class Y>
      constexpr weak_ptr(const weak_ptr<Y>& r) noexcept;
    constexpr weak_ptr(weak_ptr&& r) noexcept;
    template<class Y>
      constexpr weak_ptr(weak_ptr<Y>&& r) noexcept;

    // 20.3.2.3.3, destructor
    constexpr ~weak_ptr();

    // 20.3.2.3.4, assignment
    constexpr weak_ptr& operator=(const weak_ptr& r) noexcept;
    template<class Y>
      constexpr weak_ptr& operator=(const weak_ptr<Y>& r) noexcept;
    template<class Y>
      constexpr weak_ptr& operator=(const shared_ptr<Y>& r) noexcept;
    constexpr weak_ptr& operator=(weak_ptr&& r) noexcept;
    template<class Y>
      constexpr weak_ptr& operator=(weak_ptr<Y>&& r) noexcept;

    // 20.3.2.3.5, modifiers
    constexpr void swap(weak_ptr& r) noexcept;
    constexpr void reset() noexcept;

    // 20.3.2.3.6, observers
    constexpr long use_count() const noexcept;
    constexpr bool expired() const noexcept;
    constexpr shared_ptr<T> lock() const noexcept;
    template<class U>
      bool owner_before(const shared_ptr<U>& b) const noexcept;
    template<class U>
      bool owner_before(const weak_ptr<U>& b) const noexcept;
    size_t owner_hash() const noexcept;
    template<class U>
      constexpr bool owner_equal(const shared_ptr<U>& b) const noexcept;
    template<class U>
      constexpr bool owner_equal(const weak_ptr<U>& b) const noexcept;
  };

  template<class T>
    weak_ptr(shared_ptr<T>) -> weak_ptr<T>;
}
```

2 Specializations of `weak_ptr` shall be *Cpp17CopyConstructible* and *Cpp17CopyAssignable*, allowing their use in standard containers. The template parameter `T` of `weak_ptr` may be an incomplete type.

20.3.2.3.2 Constructors [util.smartptr.weak.const]

```
constexpr weak_ptr() noexcept;
```

1 *Effects*: Constructs an empty `weak_ptr` object that stores a null pointer value.

2 *Postconditions*: `use_count() == 0`.

```
constexpr weak_ptr(const weak_ptr& r) noexcept;
template<class Y> constexpr weak_ptr(const weak_ptr<Y>& r) noexcept;
```

```
template<class Y> constexpr weak_ptr(const shared_ptr<Y>& r) noexcept;
```

3 *Constraints*: For the second and third constructors, `Y*` is compatible with `T*`.

4 *Effects*: If `r` is empty, constructs an empty `weak_ptr` object that stores a null pointer value; otherwise, constructs a `weak_ptr` object that shares ownership with `r` and stores a copy of the pointer stored in `r`.

5 *Postconditions*: `use_count() == r.use_count()`.

```
constexpr weak_ptr(weak_ptr&& r) noexcept;
template<class Y> constexpr weak_ptr(weak_ptr<Y>&& r) noexcept;
```

6 *Constraints*: For the second constructor, `Y*` is compatible with `T*`.

7 *Effects*: Move constructs a `weak_ptr` instance from `r`.

8 *Postconditions*: `*this` contains the old value of `r`. `r` is empty, stores a null pointer value, and `r.use_count() == 0`.

20.3.2.3.3 Destructor [util.smartptr.weak.dest]

```
constexpr ~weak_ptr();
```

1 *Effects*: Destroys this `weak_ptr` object but has no effect on the object its stored pointer points to.

20.3.2.3.4 Assignment [util.smartptr.weak.assign]

```
constexpr weak_ptr& operator=(const weak_ptr& r) noexcept;
template<class Y> constexpr weak_ptr& operator=(const weak_ptr<Y>& r) noexcept;
template<class Y> constexpr weak_ptr& operator=(const shared_ptr<Y>& r) noexcept;
```

1 *Effects*: Equivalent to `weak_ptr(r).swap(*this)`.

2 *Returns*: `*this`.

3 *Remarks*: The implementation may meet the effects (and the implied guarantees) via different means, without creating a temporary object.

```
constexpr weak_ptr& operator=(weak_ptr&& r) noexcept;
template<class Y> constexpr weak_ptr& operator=(weak_ptr<Y>&& r) noexcept;
```

4 *Effects*: Equivalent to `weak_ptr(std::move(r)).swap(*this)`.

5 *Returns*: `*this`.

20.3.2.3.5 Modifiers [util.smartptr.weak.mod]

```
constexpr void swap(weak_ptr& r) noexcept;
```

1 *Effects*: Exchanges the contents of `*this` and `r`.

```
constexpr void reset() noexcept;
```

2 *Effects*: Equivalent to `weak_ptr().swap(*this)`.

20.3.2.3.6 Observers [util.smartptr.weak.obs]

```
constexpr long use_count() const noexcept;
```

1 *Returns*: `0` if `*this` is empty; otherwise, the number of `shared_ptr` instances that share ownership with `*this`.

```
constexpr bool expired() const noexcept;
```

2 *Returns*: `use_count() == 0`.

```
constexpr shared_ptr<T> lock() const noexcept;
```

3 *Returns*: `expired() ? shared_ptr<T>() : shared_ptr<T>(*this)`, executed atomically.

```
template<class U> bool owner_before(const shared_ptr<U>& b) const noexcept;
template<class U> bool owner_before(const weak_ptr<U>& b) const noexcept;
```

4 *Returns*: An unspecified value such that

(4.1) — `owner_before(b)` defines a strict weak ordering as defined in 26.8;

(4.2) — `!owner_before(b) && !b.owner_before(*this)` is `true` if and only if `owner_equal(b)` is `true`.

```
size_t owner_hash() const noexcept;
```

5 *Returns*: An unspecified value such that, for any object `x` where `owner_equal(x)` is `true`, `owner_hash() == x.owner_hash()` is `true`.

```
template<class U>
  constexpr bool owner_equal(const shared_ptr<U>& b) const noexcept;
template<class U>
  constexpr bool owner_equal(const weak_ptr<U>& b) const noexcept;
```

6 *Returns*: `true` if and only if `*this` and `b` share ownership or are both empty. Otherwise returns `false`.

7 *Remarks*: `owner_equal` is an equivalence relation.

20.3.2.3.7 Specialized algorithms [util.smartptr.weak.spec]

```
template<class T>
  constexpr void swap(weak_ptr<T>& a, weak_ptr<T>& b) noexcept;
```

1 *Effects*: Equivalent to `a.swap(b)`.

20.3.2.4 Class template `owner_less` [util.smartptr.ownerless]

1 The class template `owner_less` allows ownership-based mixed comparisons of shared and weak pointers.

```
namespace std {
  template<class T = void> struct owner_less;

  template<class T> struct owner_less<shared_ptr<T>> {
    bool operator()(const shared_ptr<T>&, const shared_ptr<T>&) const noexcept;
    bool operator()(const shared_ptr<T>&, const weak_ptr<T>&) const noexcept;
    bool operator()(const weak_ptr<T>&, const shared_ptr<T>&) const noexcept;
  };

  template<class T> struct owner_less<weak_ptr<T>> {
    bool operator()(const weak_ptr<T>&, const weak_ptr<T>&) const noexcept;
    bool operator()(const shared_ptr<T>&, const weak_ptr<T>&) const noexcept;
    bool operator()(const weak_ptr<T>&, const shared_ptr<T>&) const noexcept;
  };

  template<> struct owner_less<void> {
    template<class T, class U>
      bool operator()(const shared_ptr<T>&, const shared_ptr<U>&) const noexcept;
    template<class T, class U>
      bool operator()(const shared_ptr<T>&, const weak_ptr<U>&) const noexcept;
    template<class T, class U>
      bool operator()(const weak_ptr<T>&, const shared_ptr<U>&) const noexcept;
    template<class T, class U>
      bool operator()(const weak_ptr<T>&, const weak_ptr<U>&) const noexcept;

    using is_transparent = unspecified;
  };
}
```

2 `operator()(x, y)` returns `x.owner_before(y)`.

[*Note 1*: Note that

(2.1) — `operator()` defines a strict weak ordering as defined in 26.8;

(2.2) — `!operator()(a, b) && !operator()(b, a)` is `true` if and only if `a.owner_equal(b)` is `true`.

— *end note*]

20.3.2.5 Struct `owner_hash` [util.smartptr.owner.hash]

1 The class `owner_hash` provides ownership-based hashing.

```
namespace std {
  struct owner_hash {
    template<class T>
      size_t operator()(const shared_ptr<T>&) const noexcept;

    template<class T>
      size_t operator()(const weak_ptr<T>&) const noexcept;

    using is_transparent = unspecified;
  };
}

template<class T>
  size_t operator()(const shared_ptr<T>& x) const noexcept;
template<class T>
  size_t operator()(const weak_ptr<T>& x) const noexcept;
```

2 *Returns*: `x.owner_hash()`.

3 [*Note 1*: For any object `y` where `x.owner_equal(y)` is `true`, `x.owner_hash() == y.owner_hash()` is `true`. — *end note*]

20.3.2.6 Struct `owner_equal` [util.smartptr.owner.equal]

1 The class `owner_equal` provides ownership-based mixed equality comparisons of shared and weak pointers.

```
namespace std {
  struct owner_equal {
    template<class T, class U>
      constexpr bool operator()(const shared_ptr<T>&, const shared_ptr<U>&) const noexcept;
    template<class T, class U>
      constexpr bool operator()(const shared_ptr<T>&, const weak_ptr<U>&) const noexcept;
    template<class T, class U>
      constexpr bool operator()(const weak_ptr<T>&, const shared_ptr<U>&) const noexcept;
    template<class T, class U>
      constexpr bool operator()(const weak_ptr<T>&, const weak_ptr<U>&) const noexcept;

    using is_transparent = unspecified;
  };
}

template<class T, class U>
  constexpr bool operator()(const shared_ptr<T>& x, const shared_ptr<U>& y) const noexcept;
template<class T, class U>
  constexpr bool operator()(const shared_ptr<T>& x, const weak_ptr<U>& y) const noexcept;
template<class T, class U>
  constexpr bool operator()(const weak_ptr<T>& x, const shared_ptr<U>& y) const noexcept;
template<class T, class U>
  constexpr bool operator()(const weak_ptr<T>& x, const weak_ptr<U>& y) const noexcept;
```

2 *Returns*: `x.owner_equal(y)`.

3 [*Note 1*: `x.owner_equal(y)` is `true` if and only if `x` and `y` share ownership or are both empty. — *end note*]

20.3.2.7 Class template `enable_shared_from_this` [util.smartptr.enab]

1 A class `T` can inherit from `enable_shared_from_this<T>` to inherit the `shared_from_this` member functions that obtain a `shared_ptr` instance pointing to `*this`.

2 [*Example 1*:

```
struct X: public enable_shared_from_this<X> { };

int main() {
  shared_ptr<X> p(new X);
  shared_ptr<X> q = p->shared_from_this();
  assert(p == q);
  assert(p.owner_equal(q));                    // p and q share ownership
}
```

— *end example*]

```
namespace std {
  template<class T> class enable_shared_from_this {
  protected:
    constexpr enable_shared_from_this() noexcept;
    constexpr enable_shared_from_this(const enable_shared_from_this&) noexcept;
    constexpr enable_shared_from_this& operator=(const enable_shared_from_this&) noexcept;
    constexpr ~enable_shared_from_this();

  public:
    constexpr shared_ptr<T> shared_from_this();
    constexpr shared_ptr<T const> shared_from_this() const;
    constexpr weak_ptr<T> weak_from_this() noexcept;
    constexpr weak_ptr<T const> weak_from_this() const noexcept;

  private:
    mutable weak_ptr<T> weak-this;  // exposition only
  };
}
```

3 The template parameter `T` of `enable_shared_from_this` may be an incomplete type.

```
constexpr enable_shared_from_this() noexcept;
constexpr enable_shared_from_this(const enable_shared_from_this<T>&) noexcept;
```

4 *Effects*: Value-initializes *weak-this*.

```
constexpr enable_shared_from_this<T>& operator=(const enable_shared_from_this<T>&) noexcept;
```

5 *Returns*: `*this`.

6 [*Note 1*: *weak-this* is not changed. — *end note*]

```
constexpr shared_ptr<T>       shared_from_this();
constexpr shared_ptr<T const> shared_from_this() const;
```

7 *Returns*: `shared_ptr<T>(`*weak-this*`)`.

```
constexpr weak_ptr<T>       weak_from_this() noexcept;
constexpr weak_ptr<T const> weak_from_this() const noexcept;
```

8 *Returns*: *weak-this*.

20.3.3 Smart pointer hash support [util.smartptr.hash]

```
template<class T, class D> struct hash<unique_ptr<T, D>>;
```

1 Letting `UP` be `unique_ptr<T, D>`, the specialization `hash<UP>` is enabled (22.10.19) if and only if `hash<typename UP::pointer>` is enabled. When enabled, for an object `p` of type `UP`, `hash<UP>()(p)` evaluates to the same value as `hash<typename UP::pointer>()(p.get())`. The member functions are not guaranteed to be `noexcept`.

```
template<class T> struct hash<shared_ptr<T>>;
```

2 For an object `p` of type `shared_ptr<T>`, `hash<shared_ptr<T>>()(p)` evaluates to the same value as `hash<typename shared_ptr<T>::element_type*>()(p.get())`.

20.3.4 Smart pointer adaptors [smartptr.adapt]

20.3.4.1 Class template `out_ptr_t` [out.ptr.t]

1 `out_ptr_t` is a class template used to adapt types such as smart pointers (20.3) for functions that use output pointer parameters.

2 [*Example 1*:

```
#include <memory>
#include <cstdio>

int fopen_s(std::FILE** f, const char* name, const char* mode);
```

```
struct fclose_deleter {
  void operator()(std::FILE* f) const noexcept {
    std::fclose(f);
  }
};

int main(int, char*[]) {
  constexpr const char* file_name = "ow.o";
  std::unique_ptr<std::FILE, fclose_deleter> file_ptr;
  int err = fopen_s(std::out_ptr<std::FILE*>(file_ptr), file_name, "r+b");
  if (err != 0)
    return 1;
  // *file_ptr is valid
  return 0;
}
```

`unique_ptr` can be used with `out_ptr` to be passed into an output pointer-style function, without needing to hold onto an intermediate pointer value and manually delete it on error or failure. — *end example*]

```
namespace std {
  template<class Smart, class Pointer, class... Args>
  class out_ptr_t {
  public:
    constexpr explicit out_ptr_t(Smart&, Args...);
    out_ptr_t(const out_ptr_t&) = delete;

    constexpr ~out_ptr_t();

    constexpr operator Pointer*() const noexcept;
    operator void**() const noexcept;

  private:
    Smart& s;                    // exposition only
    tuple<Args...> a;            // exposition only
    Pointer p;                   // exposition only
  };
}
```

3 `Pointer` shall meet the *Cpp17NullablePointer* requirements. If `Smart` is a specialization of `shared_ptr` and `sizeof...(Args) == 0`, the program is ill-formed.

[*Note 1*: It is typically a user error to reset a `shared_ptr` without specifying a deleter, as `shared_ptr` will replace a custom deleter upon usage of `reset`, as specified in 20.3.2.2.5. — *end note*]

4 Program-defined specializations of `out_ptr_t` that depend on at least one program-defined type need not meet the requirements for the primary template.

5 Evaluations of the conversion functions on the same object may conflict (6.10.2.2).

```
constexpr explicit out_ptr_t(Smart& smart, Args... args);
```

6 *Effects*: Initializes `s` with `smart`, `a` with `std::forward<Args>(args)...`, and value-initializes `p`. Then, equivalent to:

(6.1) — `s.reset();`

if the expression `s.reset()` is well-formed;

(6.2) — otherwise,

```
s = Smart();
```

if `is_constructible_v<Smart>` is `true`;

(6.3) — otherwise, the program is ill-formed.

7 [*Note 2*: The constructor is not `noexcept` to allow for a variety of non-terminating and safe implementation strategies. For example, an implementation can allocate a `shared_ptr`'s internal node in the constructor and let implementation-defined exceptions escape safely. The destructor can then move the allocated control block in directly and avoid any other exceptions. — *end note*]

```
constexpr ~out_ptr_t();
```

8 Let `SP` be *`POINTER_OF_OR`*`(Smart, Pointer)` (20.2.1).

9 *Effects*: Equivalent to:

(9.1) —
```
if (p) {
  apply([&](auto&&... args) {
    s.reset(static_cast<SP>(p), std::forward<Args>(args)...); }, std::move(a));
}
```
if the expression `s.reset(static_cast<SP>(p), std::forward<Args>(args)...)` is well-formed;

(9.2) — otherwise,
```
if (p) {
  apply([&](auto&&... args) {
    s = Smart(static_cast<SP>(p), std::forward<Args>(args)...); }, std::move(a));
}
```
if `is_constructible_v<Smart, SP, Args...>` is `true`;

(9.3) — otherwise, the program is ill-formed.

```
constexpr operator Pointer*() const noexcept;
```

10 *Preconditions*: `operator void**()` has not been called on `*this`.

11 *Returns*: `addressof(const_cast<Pointer&>(p))`.

```
operator void**() const noexcept;
```

12 *Constraints*: `is_same_v<Pointer, void*>` is `false`.

13 *Mandates*: `is_pointer_v<Pointer>` is `true`.

14 *Preconditions*: `operator Pointer*()` has not been called on `*this`.

15 *Returns*: A pointer value `v` such that:

(15.1) — the initial value `*v` is equivalent to `static_cast<void*>(p)` and

(15.2) — any modification of `*v` that is not followed by a subsequent modification of `*this` affects the value of `p` during the destruction of `*this`, such that `static_cast<void*>(p) == *v`.

16 *Remarks*: Accessing `*v` outside the lifetime of `*this` has undefined behavior.

17 [*Note 3*: `reinterpret_cast<void**>(static_cast<Pointer*>(*this))` can be a viable implementation strategy for some implementations. — *end note*]

20.3.4.2 Function template `out_ptr` [out.ptr]

```
template<class Pointer = void, class Smart, class... Args>
  constexpr auto out_ptr(Smart& s, Args&&... args);
```

1 Let `P` be `Pointer` if `is_void_v<Pointer>` is `false`, otherwise *`POINTER_OF`*`(Smart)`.

2 *Returns*: `out_ptr_t<Smart, P, Args&&...>(s, std::forward<Args>(args)...)`.

20.3.4.3 Class template `inout_ptr_t` [inout.ptr.t]

1 `inout_ptr_t` is a class template used to adapt types such as smart pointers (20.3) for functions that use output pointer parameters whose dereferenced values may first be deleted before being set to another allocated value.

2 [*Example 1*:

```
#include <memory>

struct star_fish* star_fish_alloc();
int star_fish_populate(struct star_fish** ps, const char* description);

struct star_fish_deleter {
  void operator() (struct star_fish* c) const noexcept;
};
```

```
using star_fish_ptr = std::unique_ptr<star_fish, star_fish_deleter>;

int main(int, char*[]) {
  star_fish_ptr peach(star_fish_alloc());
  // ...
  // used, need to re-make
  int err = star_fish_populate(std::inout_ptr(peach), "caring clown-fish liker");
  return err;
}
```

A `unique_ptr` can be used with `inout_ptr` to be passed into an output pointer-style function. The original value will be properly deleted according to the function it is used with and a new value reset in its place. — *end example*]

```
namespace std {
  template<class Smart, class Pointer, class... Args>
  class inout_ptr_t {
  public:
    constexpr explicit inout_ptr_t(Smart&, Args...);
    inout_ptr_t(const inout_ptr_t&) = delete;

    constexpr ~inout_ptr_t();

    constexpr operator Pointer*() const noexcept;
    operator void**() const noexcept;

  private:
    Smart& s;                   // exposition only
    tuple<Args...> a;           // exposition only
    Pointer p;                  // exposition only
  };
}
```

3 `Pointer` shall meet the *Cpp17NullablePointer* requirements. If `Smart` is a specialization of `shared_ptr`, the program is ill-formed.

[*Note 1*: It is impossible to properly acquire unique ownership of the managed resource from a `shared_ptr` given its shared ownership model. — *end note*]

4 Program-defined specializations of `inout_ptr_t` that depend on at least one program-defined type need not meet the requirements for the primary template.

5 Evaluations of the conversion functions on the same object may conflict (6.10.2.2).

```
constexpr explicit inout_ptr_t(Smart& smart, Args... args);
```

6 *Effects*: Initializes `s` with `smart`, `a` with `std::forward<Args>(args)...`, and `p` to either

(6.1) — `smart` if `is_pointer_v<Smart>` is `true`,

(6.2) — otherwise, `smart.get()`.

7 *Remarks*: An implementation can call `s.release()`.

8 [*Note 2*: The constructor is not `noexcept` to allow for a variety of non-terminating and safe implementation strategies. For example, an intrusive pointer implementation with a control block can allocate in the constructor and safely fail with an exception. — *end note*]

```
constexpr ~inout_ptr_t();
```

9 Let `SP` be *`POINTER_OF_OR`*`(Smart, Pointer)` (20.2.1).

10 Let *`release-statement`* be `s.release();` if an implementation does not call `s.release()` in the constructor. Otherwise, it is empty.

11 *Effects*: Equivalent to:

(11.1) —
```
apply([&](auto&&... args) {
  s = Smart(static_cast<SP>(p), std::forward<Args>(args)...); }, std::move(a));
```
if `is_pointer_v<Smart>` is `true`;

(11.2) — otherwise,

`release-statement``;`

```
if (p) {
  apply([&](auto&&... args) {
    s.reset(static_cast<SP>(p), std::forward<Args>(args)...); }, std::move(a));
}
```

if the expression `s.reset(static_cast<SP>(p), std::forward<Args>(args)...)` is well-formed;

(11.3) — otherwise,

```
release-statement;
if (p) {
  apply([&](auto&&... args) {
    s = Smart(static_cast<SP>(p), std::forward<Args>(args)...); }, std::move(a));
}
```

if `is_constructible_v<Smart, SP, Args...>` is `true`;

(11.4) — otherwise, the program is ill-formed.

```
constexpr operator Pointer*() const noexcept;
```

12 *Preconditions*: `operator void**()` has not been called on `*this`.

13 *Returns*: `addressof(const_cast<Pointer&>(p))`.

```
operator void**() const noexcept;
```

14 *Constraints*: `is_same_v<Pointer, void*>` is `false`.

15 *Mandates*: `is_pointer_v<Pointer>` is `true`.

16 *Preconditions*: `operator Pointer*()` has not been called on `*this`.

17 *Returns*: A pointer value `v` such that:

(17.1) — the initial value `*v` is equivalent to `static_cast<void*>(p)` and

(17.2) — any modification of `*v` that is not followed by subsequent modification of `*this` affects the value of `p` during the destruction of `*this`, such that `static_cast<void*>(p) == *v`.

18 *Remarks*: Accessing `*v` outside the lifetime of `*this` has undefined behavior.

19 [*Note 3*: `reinterpret_cast<void**>(static_cast<Pointer*>(*this))` can be a viable implementation strategy for some implementations. — *end note*]

20.3.4.4 Function template `inout_ptr` [inout.ptr]

```
template<class Pointer = void, class Smart, class... Args>
  constexpr auto inout_ptr(Smart& s, Args&&... args);
```

1 Let `P` be `Pointer` if `is_void_v<Pointer>` is `false`, otherwise *`POINTER_OF`*`(Smart)`.

2 *Returns*: `inout_ptr_t<Smart, P, Args&&...>(s, std::forward<Args>(args)...)`.

20.4 Types for composite class design [mem.composite.types]

20.4.1 Class template `indirect` [indirect]

20.4.1.1 General [indirect.general]

1 An indirect object manages the lifetime of an owned object. An indirect object is *valueless* if it has no owned object. An indirect object may become valueless only after it has been moved from.

2 In every specialization `indirect<T, Allocator>`, if the type `allocator_traits<Allocator>::value_type` is not the same type as `T`, the program is ill-formed. Every object of type `indirect<T, Allocator>` uses an object of type `Allocator` to allocate and free storage for the owned object as needed.

3 Constructing an owned object with `args...` using the allocator `a` means calling `allocator_traits<Allocator>::construct(a, `*`p`*`, args...)` where `args` is an expression pack, `a` is an allocator, and *`p`* is a pointer obtained by calling `allocator_traits<Allocator>::allocate`.

4 The member *`alloc`* is used for any memory allocation and element construction performed by member functions during the lifetime of each indirect object. The allocator *`alloc`* may be replaced only via assignment or `swap()`. `Allocator` replacement is performed by copy assignment, move assignment, or swapping of the allocator only if (23.2.2.2):

(4.1) — `allocator_traits<Allocator>::propagate_on_container_copy_assignment::value`, or

(4.2) — `allocator_traits<Allocator>::propagate_on_container_move_assignment::value`, or

(4.3) — `allocator_traits<Allocator>::propagate_on_container_swap::value`

is `true` within the implementation of the corresponding `indirect` operation.

5 A program that instantiates the definition of the template `indirect<T, Allocator>` with a type for the `T` parameter that is a non-object type, an array type, `in_place_t`, a specialization of `in_place_type_t`, or a cv-qualified type is ill-formed.

6 The template parameter `T` of `indirect` may be an incomplete type.

7 The template parameter `Allocator` of `indirect` shall meet the *Cpp17Allocator* requirements.

8 If a program declares an explicit or partial specialization of `indirect`, the behavior is undefined.

20.4.1.2 Synopsis [indirect.syn]

```
namespace std {
  template<class T, class Allocator = allocator<T>>
  class indirect {
  public:
    using value_type = T;
    using allocator_type = Allocator;
    using pointer = allocator_traits<Allocator>::pointer;
    using const_pointer = allocator_traits<Allocator>::const_pointer;

    // 20.4.1.3, constructors
    constexpr explicit indirect();
    constexpr explicit indirect(allocator_arg_t, const Allocator& a);
    constexpr indirect(const indirect& other);
    constexpr indirect(allocator_arg_t, const Allocator& a, const indirect& other);
    constexpr indirect(indirect&& other) noexcept;
    constexpr indirect(allocator_arg_t, const Allocator& a, indirect&& other)
      noexcept(see below);
    template<class U = T>
      constexpr explicit indirect(U&& u);
    template<class U = T>
      constexpr explicit indirect(allocator_arg_t, const Allocator& a, U&& u);
    template<class... Us>
      constexpr explicit indirect(in_place_t, Us&&... us);
    template<class... Us>
      constexpr explicit indirect(allocator_arg_t, const Allocator& a,
                                  in_place_t, Us&&... us);
    template<class I, class... Us>
      constexpr explicit indirect(in_place_t, initializer_list<I> ilist, Us&&... us);
    template<class I, class... Us>
      constexpr explicit indirect(allocator_arg_t, const Allocator& a,
                                  in_place_t, initializer_list<I> ilist, Us&&... us);

    // 20.4.1.4, destructor
    constexpr ~indirect();

    // 20.4.1.5, assignment
    constexpr indirect& operator=(const indirect& other);
    constexpr indirect& operator=(indirect&& other) noexcept(see below);
    template<class U = T>
      constexpr indirect& operator=(U&& u);

    // 20.4.1.6, observers
    constexpr const T& operator*() const & noexcept;
    constexpr T& operator*() & noexcept;
    constexpr const T&& operator*() const && noexcept;
    constexpr T&& operator*() && noexcept;
    constexpr const_pointer operator->() const noexcept;
    constexpr pointer operator->() noexcept;
```

```
    constexpr bool valueless_after_move() const noexcept;
    constexpr allocator_type get_allocator() const noexcept;

    // 20.4.1.7, swap
    constexpr void swap(indirect& other) noexcept(see below);
    friend constexpr void swap(indirect& lhs, indirect& rhs) noexcept(see below);

    // 20.4.1.8, relational operators
    template<class U, class AA>
      friend constexpr bool operator==(const indirect& lhs, const indirect<U, AA>& rhs)
        noexcept(see below);
    template<class U, class AA>
      friend constexpr auto operator<=>(const indirect& lhs, const indirect<U, AA>& rhs)
        -> synth-three-way-result<T, U>;

    // 20.4.1.9, comparison with T
    template<class U>
      friend constexpr bool operator==(const indirect& lhs, const U& rhs) noexcept(see below);
    template<class U>
      friend constexpr auto operator<=>(const indirect& lhs, const U& rhs)
        -> synth-three-way-result<T, U>;

  private:
    pointer p;                          // exposition only
    Allocator alloc = Allocator();      // exposition only
  };
  template<class Value>
    indirect(Value) -> indirect<Value>;
  template<class Allocator, class Value>
    indirect(allocator_arg_t, Allocator, Value)
      -> indirect<Value, typename allocator_traits<Allocator>::template rebind_alloc<Value>>;
}
```

20.4.1.3 Constructors [indirect.ctor]

1 The following element applies to all functions in 20.4.1.3:

2 *Throws*: Nothing unless `allocator_traits<Allocator>::allocate` or `allocator_traits<Allocator>::construct` throws.

```
constexpr explicit indirect();
```

3 *Constraints*: `is_default_constructible_v<Allocator>` is `true`.

4 *Mandates*: `is_default_constructible_v<T>` is `true`.

5 *Effects*: Constructs an owned object of type `T` with an empty argument list, using the allocator *alloc*.

```
constexpr explicit indirect(allocator_arg_t, const Allocator& a);
```

6 *Mandates*: `is_default_constructible_v<T>` is `true`.

7 *Effects*: *alloc* is direct-non-list-initialized with `a`. Constructs an owned object of type `T` with an empty argument list, using the allocator *alloc*.

```
constexpr indirect(const indirect& other);
```

8 *Mandates*: `is_copy_constructible_v<T>` is `true`.

9 *Effects*: *alloc* is direct-non-list-initialized with `allocator_traits<Allocator>::select_on_container_copy_construction(other.`*alloc*`)`. If `other` is valueless, `*this` is valueless. Otherwise, constructs an owned object of type `T` with `*other`, using the allocator *alloc*.

```
constexpr indirect(allocator_arg_t, const Allocator& a, const indirect& other);
```

10 *Mandates*: `is_copy_constructible_v<T>` is `true`.

11 *Effects*: *alloc* is direct-non-list-initialized with `a`. If `other` is valueless, `*this` is valueless. Otherwise, constructs an owned object of type `T` with `*other`, using the allocator *alloc*.

```
constexpr indirect(indirect&& other) noexcept;
```

12 *Effects*: *alloc* is direct-non-list-initialized from `std::move(other.`*alloc*`)`. If `other` is valueless, `*this` is valueless. Otherwise `*this` takes ownership of the owned object of `other`.

13 *Postconditions*: `other` is valueless.

```
constexpr indirect(allocator_arg_t, const Allocator& a, indirect&& other)
  noexcept(allocator_traits<Allocator>::is_always_equal::value);
```

14 *Mandates*: If `allocator_traits<Allocator>::is_always_equal::value` is `false` then `T` is a complete type.

15 *Effects*: *alloc* is direct-non-list-initialized with `a`. If `other` is valueless, `*this` is valueless. Otherwise, if *alloc* `== other.`*alloc* is `true`, constructs an object of type `indirect` that takes ownership of the owned object of `other`. Otherwise, constructs an owned object of type `T` with `*std::move(other)`, using the allocator *alloc*.

16 *Postconditions*: `other` is valueless.

```
template<class U = T>
  constexpr explicit indirect(U&& u);
```

17 *Constraints*:

(17.1) — `is_same_v<remove_cvref_t<U>, indirect>` is `false`,

(17.2) — `is_same_v<remove_cvref_t<U>, in_place_t>` is `false`,

(17.3) — `is_constructible_v<T, U>` is `true`, and

(17.4) — `is_default_constructible_v<Allocator>` is `true`.

18 *Effects*: Constructs an owned object of type `T` with `std::forward<U>(u)`, using the allocator *alloc*.

```
template<class U = T>
  constexpr explicit indirect(allocator_arg_t, const Allocator& a, U&& u);
```

19 *Constraints*:

(19.1) — `is_same_v<remove_cvref_t<U>, indirect>` is `false`,

(19.2) — `is_same_v<remove_cvref_t<U>, in_place_t>` is `false`, and

(19.3) — `is_constructible_v<T, U>` is `true`.

20 *Effects*: *alloc* is direct-non-list-initialized with `a`. Constructs an owned object of type `T` with `std::forward<U>(u)`, using the allocator *alloc*.

```
template<class... Us>
  constexpr explicit indirect(in_place_t, Us&&... us);
```

21 *Constraints*:

(21.1) — `is_constructible_v<T, Us...>` is `true`, and

(21.2) — `is_default_constructible_v<Allocator>` is `true`.

22 *Effects*: Constructs an owned object of type `T` with `std::forward<Us>(us)...`, using the allocator *alloc*.

```
template<class... Us>
  constexpr explicit indirect(allocator_arg_t, const Allocator& a,
                              in_place_t, Us&& ...us);
```

23 *Constraints*: `is_constructible_v<T, Us...>` is `true`.

24 *Effects*: *alloc* is direct-non-list-initialized with `a`. Constructs an owned object of type `T` with `std::forward<Us>(us)...`, using the allocator *alloc*.

```
template<class I, class... Us>
  constexpr explicit indirect(in_place_t, initializer_list<I> ilist, Us&&... us);
```

25 *Constraints*:

(25.1) — `is_constructible_v<T, initializer_list<I>&, Us...>` is `true`, and

(25.2) — `is_default_constructible_v<Allocator>` is `true`.

26 *Effects*: Constructs an owned object of type `T` with the arguments `ilist, std::forward<Us>(us)...`, using the allocator *`alloc`*.

```
template<class I, class... Us>
  constexpr explicit indirect(allocator_arg_t, const Allocator& a,
                              in_place_t, initializer_list<I> ilist, Us&&... us);
```

27 *Constraints*: `is_constructible_v<T, initializer_list<I>&, Us...>` is `true`.

28 *Effects*: *`alloc`* is direct-non-list-initialized with `a`. Constructs an owned object of type `T` with the arguments `ilist, std::forward<Us>(us)...`, using the allocator *`alloc`*.

20.4.1.4 Destructor [indirect.dtor]

```
constexpr ~indirect();
```

1 *Mandates*: `T` is a complete type.

2 *Effects*: If `*this` is not valueless, destroys the owned object using `allocator_traits<Allocator>::destroy` and then the storage is deallocated.

20.4.1.5 Assignment [indirect.assign]

```
constexpr indirect& operator=(const indirect& other);
```

1 *Mandates*:

(1.1) — `is_copy_assignable_v<T>` is `true`, and

(1.2) — `is_copy_constructible_v<T>` is `true`.

2 *Effects*: If `addressof(other) == this` is `true`, there are no effects. Otherwise:

(2.1) — The allocator needs updating if `allocator_traits<Allocator>::propagate_on_container_copy_assignment::value` is `true`.

(2.2) — If `other` is valueless, `*this` becomes valueless and the owned object in `*this`, if any, is destroyed using `allocator_traits<Allocator>::destroy` and then the storage is deallocated.

(2.3) — Otherwise, if *`alloc`* `== other.`*`alloc`* is `true` and `*this` is not valueless, equivalent to `**this = *other`.

(2.4) — Otherwise a new owned object is constructed in `*this` using `allocator_traits<Allocator>::construct` with the owned object from `other` as the argument, using either the allocator in `*this` or the allocator in `other` if the allocator needs updating.

(2.5) — The previously owned object in `*this`, if any, is destroyed using `allocator_traits<Allocator>::destroy` and then the storage is deallocated.

(2.6) — If the allocator needs updating, the allocator in `*this` is replaced with a copy of the allocator in `other`.

3 *Returns*: A reference to `*this`.

4 *Remarks*: If any exception is thrown, the result of the expression `this->valueless_after_move()` remains unchanged. If an exception is thrown during the call to `T`'s selected copy constructor, no effect. If an exception is thrown during the call to `T`'s copy assignment, the state of its owned object is as defined by the exception safety guarantee of `T`'s copy assignment.

```
constexpr indirect& operator=(indirect&& other)
  noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
           allocator_traits<Allocator>::is_always_equal::value);
```

5 *Mandates*: If `allocator_traits<Allocator>::propagate_on_container_move_assignment::value` is `false` and `allocator_traits<Allocator>::is_always_equal::value` is `false`, `is_move_constructible_v<T>` is `true`.

6 *Effects*: If `addressof(other) == this` is `true`, there are no effects. Otherwise:

(6.1) — The allocator needs updating if `allocator_traits<Allocator>::propagate_on_container_move_assignment::value` is `true`.

(6.2) — If `other` is valueless, `*this` becomes valueless.

(6.3) — Otherwise, if the allocator needs updating or if *alloc* == other.*alloc* is true, *this takes ownership of the owned object of other.

(6.4) — Otherwise, constructs a new owned object with the owned object of other as the argument as an rvalue, using the allocator in *this.

(6.5) — The previously owned object in *this, if any, is destroyed using allocator_traits<Allocator>::destroy and then the storage is deallocated.

(6.6) — If the allocator needs updating, the allocator in *this is replaced with a copy of the allocator in other.

7 *Postconditions*: other is valueless.

8 *Returns*: A reference to *this.

9 *Remarks*: If any exception is thrown, there are no effects on *this or other.

```
template<class U = T>
  constexpr indirect& operator=(U&& u);
```

10 *Constraints*:

(10.1) — is_same_v<remove_cvref_t<U>, indirect> is false,

(10.2) — is_constructible_v<T, U> is true, and

(10.3) — is_assignable_v<T&, U> is true.

11 *Effects*: If *this is valueless then constructs an owned object of type T with std::forward<U>(u) using the allocator *alloc*. Otherwise, equivalent to **this = std::forward<U>(u).

12 *Returns*: A reference to *this.

20.4.1.6 Observers [indirect.obs]

```
constexpr const T& operator*() const & noexcept;
constexpr T& operator*() & noexcept;
```

1 *Preconditions*: *this is not valueless.

2 *Returns*: **p*.

```
constexpr const T&& operator*() const && noexcept;
constexpr T&& operator*() && noexcept;
```

3 *Preconditions*: *this is not valueless.

4 *Returns*: std::move(**p*).

```
constexpr const_pointer operator->() const noexcept;
constexpr pointer operator->() noexcept;
```

5 *Preconditions*: *this is not valueless.

6 *Returns*: *p*.

```
constexpr bool valueless_after_move() const noexcept;
```

7 *Returns*: true if *this is valueless, otherwise false.

```
constexpr allocator_type get_allocator() const noexcept;
```

8 *Returns*: *alloc*.

20.4.1.7 Swap [indirect.swap]

```
constexpr void swap(indirect& other)
  noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
           allocator_traits<Allocator>::is_always_equal::value);
```

1 *Preconditions*: If allocator_traits<Allocator>::propagate_on_container_swap::value is true, then Allocator meets the *Cpp17Swappable* requirements. Otherwise get_allocator() == other.get_allocator() is true.

2 *Effects*: Swaps the states of `*this` and `other`, exchanging owned objects or valueless states. If `allocator_traits<Allocator>::propagate_on_container_swap::value` is `true`, then the allocators of `*this` and `other` are exchanged by calling `swap` as described in 16.4.4.3. Otherwise, the allocators are not swapped.

[*Note 1*: Does not call `swap` on the owned objects directly. — *end note*]

```
constexpr void swap(indirect& lhs, indirect& rhs) noexcept(noexcept(lhs.swap(rhs)));
```

3 *Effects*: Equivalent to `lhs.swap(rhs)`.

20.4.1.8 Relational operators [indirect.relops]

```
template<class U, class AA>
  constexpr bool operator==(const indirect& lhs, const indirect<U, AA>& rhs)
    noexcept(noexcept(bool(*lhs == *rhs)));
```

1 *Mandates*: The expression `*lhs == *rhs` is well-formed and its result is convertible to `bool`.

2 *Returns*: If `lhs` is valueless or `rhs` is valueless, `lhs.valueless_after_move() == rhs.valueless_after_move()`; otherwise `*lhs == *rhs`.

```
template<class U, class AA>
  constexpr synth-three-way-result<T, U>
    operator<=>(const indirect& lhs, const indirect<U, AA>& rhs);
```

3 *Returns*: If `lhs` is valueless or `rhs` is valueless, `!lhs.valueless_after_move() <=> !rhs.valueless_after_move()`; otherwise *synth-three-way*`(*lhs, *rhs)`.

20.4.1.9 Comparison with `T` [indirect.comp.with.t]

```
template<class U>
  constexpr bool operator==(const indirect& lhs, const U& rhs)
    noexcept(noexcept(bool(*lhs == rhs)));
```

1 *Mandates*: The expression `*lhs == rhs` is well-formed and its result is convertible to `bool`.

2 *Returns*: If `lhs` is valueless, `false`; otherwise `*lhs == rhs`.

```
template<class U>
  constexpr synth-three-way-result<T, U>
    operator<=>(const indirect& lhs, const U& rhs);
```

3 *Returns*: If `lhs` is valueless, `strong_ordering::less`; otherwise *synth-three-way*`(*lhs, rhs)`.

20.4.1.10 Hash support [indirect.hash]

```
template<class T, class Allocator>
struct hash<indirect<T, Allocator>>;
```

1 The specialization `hash<indirect<T, Allocator>>` is enabled (22.10.19) if and only if `hash<T>` is enabled. When enabled for an object `i` of type `indirect<T, Allocator>`, `hash<indirect<T, Allocator>>()(i)` evaluates to either the same value as `hash<T>()(*i)`, if `i` is not valueless; otherwise to an implementation-defined value. The member functions are not guaranteed to be `noexcept`.

20.4.2 Class template `polymorphic` [polymorphic]

20.4.2.1 General [polymorphic.general]

1 A polymorphic object manages the lifetime of an owned object. A polymorphic object may own objects of different types at different points in its lifetime. A polymorphic object is *valueless* if it has no owned object. A polymorphic object may become valueless only after it has been moved from.

2 In every specialization `polymorphic<T, Allocator>`, if the type `allocator_traits<Allocator>::value_type` is not the same type as `T`, the program is ill-formed. Every object of type `polymorphic<T, Allocator>` uses an object of type `Allocator` to allocate and free storage for the owned object as needed.

3 Constructing an owned object of type `U` with `args...` using the allocator `a` means calling `allocator_traits<Allocator>::construct(a, p, args...)` where `args` is an expression pack, `a` is an allocator, and *p* points to storage suitable for an owned object of type `U`.

4 The member *alloc* is used for any memory allocation and element construction performed by member functions during the lifetime of each polymorphic value object, or until the allocator is replaced. The allocator may be replaced only via assignment or `swap()`. `Allocator` replacement is performed by copy assignment, move assignment, or swapping of the allocator only if (23.2.2.2):

(4.1) — `allocator_traits<Allocator>::propagate_on_container_copy_assignment::value`, or

(4.2) — `allocator_traits<Allocator>::propagate_on_container_move_assignment::value`, or

(4.3) — `allocator_traits<Allocator>::propagate_on_container_swap::value`

is `true` within the implementation of the corresponding `polymorphic` operation.

5 A program that instantiates the definition of `polymorphic` for a non-object type, an array type, `in_place_t`, a specialization of `in_place_type_t`, or a cv-qualified type is ill-formed.

6 The template parameter `T` of `polymorphic` may be an incomplete type.

7 The template parameter `Allocator` of `polymorphic` shall meet the requirements of *Cpp17Allocator*.

8 If a program declares an explicit or partial specialization of `polymorphic`, the behavior is undefined.

20.4.2.2 Synopsis [polymorphic.syn]

```
namespace std {
  template<class T, class Allocator = allocator<T>>
  class polymorphic {
  public:
    using value_type = T;
    using allocator_type = Allocator;
    using pointer = allocator_traits<Allocator>::pointer;
    using const_pointer = allocator_traits<Allocator>::const_pointer;

    // 20.4.2.3, constructors
    constexpr explicit polymorphic();
    constexpr explicit polymorphic(allocator_arg_t, const Allocator& a);
    constexpr polymorphic(const polymorphic& other);
    constexpr polymorphic(allocator_arg_t, const Allocator& a, const polymorphic& other);
    constexpr polymorphic(polymorphic&& other) noexcept;
    constexpr polymorphic(allocator_arg_t, const Allocator& a, polymorphic&& other)
      noexcept(see below);
    template<class U = T>
      constexpr explicit polymorphic(U&& u);
    template<class U = T>
      constexpr explicit polymorphic(allocator_arg_t, const Allocator& a, U&& u);
    template<class U, class... Ts>
      constexpr explicit polymorphic(in_place_type_t<U>, Ts&&... ts);
    template<class U, class... Ts>
      constexpr explicit polymorphic(allocator_arg_t, const Allocator& a,
                                     in_place_type_t<U>, Ts&&... ts);
    template<class U, class I, class... Us>
      constexpr explicit polymorphic(in_place_type_t<U>, initializer_list<I> ilist, Us&&... us);
    template<class U, class I, class... Us>
      constexpr explicit polymorphic(allocator_arg_t, const Allocator& a,
                                     in_place_type_t<U>, initializer_list<I> ilist, Us&&... us);

    // 20.4.2.4, destructor
    constexpr ~polymorphic();

    // 20.4.2.5, assignment
    constexpr polymorphic& operator=(const polymorphic& other);
    constexpr polymorphic& operator=(polymorphic&& other) noexcept(see below);

    // 20.4.2.6, observers
    constexpr const T& operator*() const noexcept;
    constexpr T& operator*() noexcept;
    constexpr const_pointer operator->() const noexcept;
    constexpr pointer operator->() noexcept;
```

```
    constexpr bool valueless_after_move() const noexcept;
    constexpr allocator_type get_allocator() const noexcept;

    // 20.4.2.7, swap
    constexpr void swap(polymorphic& other) noexcept(see below);
    friend constexpr void swap(polymorphic& lhs, polymorphic& rhs) noexcept(see below);

  private:
    Allocator alloc = Allocator();      // exposition only
  };
}
```

20.4.2.3 Constructors [polymorphic.ctor]

1 The following element applies to all functions in 20.4.2.3:

2 *Throws*: Nothing unless `allocator_traits<Allocator>::allocate` or `allocator_traits<Allocator>::construct` throws.

```
constexpr explicit polymorphic();
```

3 *Constraints*: `is_default_constructible_v<Allocator>` is `true`.

4 *Mandates*:

(4.1) — `is_default_constructible_v<T>` is `true`, and

(4.2) — `is_copy_constructible_v<T>` is `true`.

5 *Effects*: Constructs an owned object of type `T` with an empty argument list using the allocator *alloc*.

```
constexpr explicit polymorphic(allocator_arg_t, const Allocator& a);
```

6 *Mandates*:

(6.1) — `is_default_constructible_v<T>` is `true`, and

(6.2) — `is_copy_constructible_v<T>` is `true`.

7 *Effects*: *alloc* is direct-non-list-initialized with `a`. Constructs an owned object of type `T` with an empty argument list using the allocator *alloc*.

```
constexpr polymorphic(const polymorphic& other);
```

8 *Effects*: *alloc* is direct-non-list-initialized with `allocator_traits<Allocator>::select_on_container_copy_construction(other.`*alloc*`)`. If `other` is valueless, `*this` is valueless. Otherwise, constructs an owned object of type `U`, where `U` is the type of the owned object in `other`, with the owned object in `other` using the allocator *alloc*.

```
constexpr polymorphic(allocator_arg_t, const Allocator& a, const polymorphic& other);
```

9 *Effects*: *alloc* is direct-non-list-initialized with `a`. If `other` is valueless, `*this` is valueless. Otherwise, constructs an owned object of type `U`, where `U` is the type of the owned object in `other`, with the owned object in `other` using the allocator *alloc*.

```
constexpr polymorphic(polymorphic&& other) noexcept;
```

10 *Effects*: *alloc* is direct-non-list-initialized with `std::move(other.`*alloc*`)`. If `other` is valueless, `*this` is valueless. Otherwise, either `*this` takes ownership of the owned object of `other` or, owns an object of the same type constructed from the owned object of `other` considering that owned object as an rvalue, using the allocator *alloc*.

```
constexpr polymorphic(allocator_arg_t, const Allocator& a, polymorphic&& other)
  noexcept(allocator_traits<Allocator>::is_always_equal::value);
```

11 *Effects*: *alloc* is direct-non-list-initialized with `a`. If `other` is valueless, `*this` is valueless. Otherwise, if *alloc* `== other.`*alloc* is `true`, either constructs an object of type `polymorphic` that owns the owned object of `other`, making `other` valueless; or, owns an object of the same type constructed from the owned object of `other` considering that owned object as an rvalue. Otherwise, if *alloc* `!= other.`*alloc* is `true`, constructs an owned object of type `U`, where `U` is the type of the owned object in `other`, with the owned object in `other` as an rvalue, using the allocator *alloc*.

```
template<class U = T>
  constexpr explicit polymorphic(U&& u);
```

12 *Constraints*: Where `UU` is `remove_cvref_t<U>`,

(12.1) — `is_same_v<UU, polymorphic>` is `false`,

(12.2) — `derived_from<UU, T>` is `true`,

(12.3) — `is_constructible_v<UU, U>` is `true`,

(12.4) — `is_copy_constructible_v<UU>` is `true`,

(12.5) — `UU` is not a specialization of `in_place_type_t`, and

(12.6) — `is_default_constructible_v<Allocator>` is `true`.

13 *Effects*: Constructs an owned object of type `UU` with `std::forward<U>(u)` using the allocator *`alloc`*.

```
template<class U = T>
  constexpr explicit polymorphic(allocator_arg_t, const Allocator& a, U&& u);
```

14 *Constraints*: Where `UU` is `remove_cvref_t<U>`,

(14.1) — `is_same_v<UU, polymorphic>` is `false`,

(14.2) — `derived_from<UU, T>` is `true`,

(14.3) — `is_constructible_v<UU, U>` is `true`,

(14.4) — `is_copy_constructible_v<UU>` is `true`, and

(14.5) — `UU` is not a specialization of `in_place_type_t`.

15 *Effects*: *`alloc`* is direct-non-list-initialized with `a`. Constructs an owned object of type `UU` with `std::forward<U>(u)` using the allocator *`alloc`*.

```
template<class U, class... Ts>
  constexpr explicit polymorphic(in_place_type_t<U>, Ts&&... ts);
```

16 *Constraints*:

(16.1) — `is_same_v<remove_cvref_t<U>, U>` is `true`,

(16.2) — `derived_from<U, T>` is `true`,

(16.3) — `is_constructible_v<U, Ts...>` is `true`,

(16.4) — `is_copy_constructible_v<U>` is `true`, and

(16.5) — `is_default_constructible_v<Allocator>` is `true`.

17 *Effects*: Constructs an owned object of type `U` with `std::forward<Ts>(ts)...` using the allocator *`alloc`*.

```
template<class U, class... Ts>
  constexpr explicit polymorphic(allocator_arg_t, const Allocator& a,
                                 in_place_type_t<U>, Ts&&... ts);
```

18 *Constraints*:

(18.1) — `is_same_v<remove_cvref_t<U>, U>` is `true`,

(18.2) — `derived_from<U, T>` is `true`,

(18.3) — `is_constructible_v<U, Ts...>` is `true`, and

(18.4) — `is_copy_constructible_v<U>` is `true`.

19 *Effects*: *`alloc`* is direct-non-list-initialized with `a`. Constructs an owned object of type `U` with `std::forward<Ts>(ts)...` using the allocator *`alloc`*.

```
template<class U, class I, class... Us>
  constexpr explicit polymorphic(in_place_type_t<U>, initializer_list<I> ilist, Us&&... us);
```

20 *Constraints*:

(20.1) — `is_same_v<remove_cvref_t<U>, U>` is `true`,

(20.2) — `derived_from<U, T>` is `true`,

(20.3) — `is_constructible_v<U, initializer_list<I>&, Us...>` is `true`,

(20.4) — `is_copy_constructible_v<U>` is `true`, and

(20.5) — `is_default_constructible_v<Allocator>` is `true`.

21 *Effects*: Constructs an owned object of type `U` with the arguments `ilist, std::forward<Us>(us)...` using the allocator *`alloc`*.

```
template<class U, class I, class... Us>
  constexpr explicit polymorphic(allocator_arg_t, const Allocator& a,
                                 in_place_type_t<U>, initializer_list<I> ilist, Us&&... us);
```

22 *Constraints*:

(22.1) — `is_same_v<remove_cvref_t<U>, U>` is `true`,

(22.2) — `derived_from<U, T>` is `true`,

(22.3) — `is_constructible_v<U, initializer_list<I>&, Us...>` is `true`, and

(22.4) — `is_copy_constructible_v<U>` is `true`.

23 *Effects*: *`alloc`* is direct-non-list-initialized with `a`. Constructs an owned object of type `U` with the arguments `ilist, std::forward<Us>(us)...` using the allocator *`alloc`*.

20.4.2.4 Destructor [polymorphic.dtor]

```
constexpr ~polymorphic();
```

1 *Mandates*: `T` is a complete type.

2 *Effects*: If `*this` is not valueless, calls `allocator_traits<Allocator>::destroy(p)`, where `p` is a pointer of type `U*` to the owned object and `U` is the type of the owned object; then the storage is deallocated.

20.4.2.5 Assignment [polymorphic.assign]

```
constexpr polymorphic& operator=(const polymorphic& other);
```

1 *Mandates*: `T` is a complete type.

2 *Effects*: If `addressof(other) == this` is `true`, there are no effects. Otherwise:

(2.1) — The allocator needs updating if `allocator_traits<Allocator>::propagate_on_container_copy_assignment::value` is `true`.

(2.2) — If `other` is not valueless, a new owned object of type `U`, where `U` is the type of the owned object in `other`, is constructed in `*this` using `allocator_traits<Allocator>::construct` with the owned object from `other` as the argument, using either the allocator in `*this` or the allocator in `other` if the allocator needs updating.

(2.3) — The previously owned object in `*this`, if any, is destroyed using `allocator_traits<Allocator>::destroy` and then the storage is deallocated.

(2.4) — If the allocator needs updating, the allocator in `*this` is replaced with a copy of the allocator in `other`.

3 *Returns*: A reference to `*this`.

4 *Remarks*: If any exception is thrown, there are no effects on `*this`.

```
constexpr polymorphic& operator=(polymorphic&& other)
  noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
           allocator_traits<Allocator>::is_always_equal::value);
```

5 *Mandates*: If `allocator_traits<Allocator>::propagate_on_container_move_assignment::value` is `false` and `allocator_traits<Allocator>::is_always_equal::value` is `false`, `T` is a complete type.

6 *Effects*: If `addressof(other) == this` is `true`, there are no effects. Otherwise:

(6.1) — The allocator needs updating if `allocator_traits<Allocator>::propagate_on_container_move_assignment::value` is `true`.

(6.2) — If `other` is valueless, `*this` becomes valueless.

(6.3) — Otherwise, if the allocator needs updating or *alloc* == other.*alloc* is true, *this takes ownership of the owned object of other.

(6.4) — Otherwise, constructs a new owned object of type U, where U is the type of the owned object in other, with the owned object of other as the argument as an rvalue, using the allocator in *this.

(6.5) — The previously owned object in *this, if any, is destroyed using allocator_traits<Allocator>::destroy and then the storage is deallocated.

(6.6) — If the allocator needs updating, the allocator in *this is replaced with a copy of the allocator in other.

7 *Returns*: A reference to *this.

8 *Remarks*: If any exception is thrown, there are no effects on *this or other.

20.4.2.6 Observers [polymorphic.obs]

```
constexpr const T& operator*() const noexcept;
constexpr T& operator*() noexcept;
```

1 *Preconditions*: *this is not valueless.

2 *Returns*: A reference to the owned object.

```
constexpr const_pointer operator->() const noexcept;
constexpr pointer operator->() noexcept;
```

3 *Preconditions*: *this is not valueless.

4 *Returns*: A pointer to the owned object.

```
constexpr bool valueless_after_move() const noexcept;
```

5 *Returns*: true if *this is valueless, otherwise false.

```
constexpr allocator_type get_allocator() const noexcept;
```

6 *Returns*: *alloc*.

20.4.2.7 Swap [polymorphic.swap]

```
constexpr void swap(polymorphic& other)
  noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
           allocator_traits<Allocator>::is_always_equal::value);
```

1 *Preconditions*: If allocator_traits<Allocator>::propagate_on_container_swap::value is true, then Allocator meets the *Cpp17Swappable* requirements. Otherwise get_allocator() == other.get_allocator() is true.

2 *Effects*: Swaps the states of *this and other, exchanging owned objects or valueless states. If allocator_traits<Allocator>::propagate_on_container_swap::value is true, then the allocators of *this and other are exchanged by calling swap as described in 16.4.4.3. Otherwise, the allocators are not swapped.

[*Note 1*: Does not call swap on the owned objects directly. — *end note*]

```
constexpr void swap(polymorphic& lhs, polymorphic& rhs) noexcept(noexcept(lhs.swap(rhs)));
```

3 *Effects*: Equivalent to lhs.swap(rhs).

20.5 Memory resources [mem.res]

20.5.1 Header <memory_resource> synopsis [mem.res.syn]

```
namespace std::pmr {
  // 20.5.2, class memory_resource
  class memory_resource;

  bool operator==(const memory_resource& a, const memory_resource& b) noexcept;

  // 20.5.3, class template polymorphic_allocator
  template<class Tp = byte> class polymorphic_allocator;
```

```
  template<class T1, class T2>
    bool operator==(const polymorphic_allocator<T1>& a,
                    const polymorphic_allocator<T2>& b) noexcept;

  // 20.5.4, global memory resources
  memory_resource* new_delete_resource() noexcept;
  memory_resource* null_memory_resource() noexcept;
  memory_resource* set_default_resource(memory_resource* r) noexcept;
  memory_resource* get_default_resource() noexcept;

  // 20.5.5, pool resource classes
  struct pool_options;
  class synchronized_pool_resource;
  class unsynchronized_pool_resource;
  class monotonic_buffer_resource;
}
```

20.5.2 Class `memory_resource` [mem.res.class]

20.5.2.1 General [mem.res.class.general]

1 The `memory_resource` class is an abstract interface to an unbounded set of classes encapsulating memory resources.

```
namespace std::pmr {
  class memory_resource {
    static constexpr size_t max_align = alignof(max_align_t);    // exposition only

  public:
    memory_resource() = default;
    memory_resource(const memory_resource&) = default;
    virtual ~memory_resource();

    memory_resource& operator=(const memory_resource&) = default;

    void* allocate(size_t bytes, size_t alignment = max_align);
    void deallocate(void* p, size_t bytes, size_t alignment = max_align);

    bool is_equal(const memory_resource& other) const noexcept;

  private:
    virtual void* do_allocate(size_t bytes, size_t alignment) = 0;
    virtual void do_deallocate(void* p, size_t bytes, size_t alignment) = 0;

    virtual bool do_is_equal(const memory_resource& other) const noexcept = 0;
  };
}
```

20.5.2.2 Public member functions [mem.res.public]

`~memory_resource();`

1 *Effects*: Destroys this `memory_resource`.

`void* allocate(size_t bytes, size_t alignment = max_align);`

2 *Effects*: Allocates storage by calling `do_allocate(bytes, alignment)` and implicitly creates objects within the allocated region of storage.

3 *Returns*: A pointer to a suitable created object (6.8.2) in the allocated region of storage.

4 *Throws*: What and when the call to `do_allocate` throws.

`void deallocate(void* p, size_t bytes, size_t alignment = max_align);`

5 *Effects*: Equivalent to `do_deallocate(p, bytes, alignment)`.

`bool is_equal(const memory_resource& other) const noexcept;`

6 *Effects*: Equivalent to: `return do_is_equal(other);`

20.5.2.3 Private virtual member functions [mem.res.private]

```
virtual void* do_allocate(size_t bytes, size_t alignment) = 0;
```

1 *Preconditions*: `alignment` is a power of two.

2 *Returns*: A derived class shall implement this function to return a pointer to allocated storage (6.8.6.5.2) with a size of at least `bytes`, aligned to the specified `alignment`.

3 *Throws*: A derived class implementation shall throw an appropriate exception if it is unable to allocate memory with the requested size and alignment.

```
virtual void do_deallocate(void* p, size_t bytes, size_t alignment) = 0;
```

4 *Preconditions*: `p` was returned from a prior call to `allocate(bytes, alignment)` on a memory resource equal to `*this`, and the storage at `p` has not yet been deallocated.

5 *Effects*: A derived class shall implement this function to dispose of allocated storage.

6 *Throws*: Nothing.

```
virtual bool do_is_equal(const memory_resource& other) const noexcept = 0;
```

7 *Returns*: A derived class shall implement this function to return `true` if memory allocated from `*this` can be deallocated from `other` and vice-versa, otherwise `false`.

[*Note 1*: It is possible that the most-derived type of `other` does not match the type of `*this`. For a derived class `D`, an implementation of this function can immediately return `false` if `dynamic_cast<const D*>(&other) == nullptr`. — *end note*]

20.5.2.4 Equality [mem.res.eq]

```
bool operator==(const memory_resource& a, const memory_resource& b) noexcept;
```

1 *Returns*: `&a == &b || a.is_equal(b)`.

20.5.3 Class template `polymorphic_allocator` [mem.poly.allocator.class]

20.5.3.1 General [mem.poly.allocator.class.general]

1 A specialization of class template `pmr::polymorphic_allocator` meets the *Cpp17Allocator* requirements (16.4.4.6.1) if its template argument is a *cv*-unqualified object type. Constructed with different memory resources, different instances of the same specialization of `pmr::polymorphic_allocator` can exhibit entirely different allocation behavior. This runtime polymorphism allows objects that use `polymorphic_allocator` to behave as if they used different allocator types at run time even though they use the same static allocator type.

2 A specialization of class template `pmr::polymorphic_allocator` meets the allocator completeness requirements (16.4.4.6.2) if its template argument is a *cv*-unqualified object type.

```
namespace std::pmr {
  template<class Tp = byte> class polymorphic_allocator {
    memory_resource* memory_rsrc;       // exposition only

  public:
    using value_type = Tp;

    // 20.5.3.2, constructors
    polymorphic_allocator() noexcept;
    polymorphic_allocator(memory_resource* r);

    polymorphic_allocator(const polymorphic_allocator& other) = default;

    template<class U>
      polymorphic_allocator(const polymorphic_allocator<U>& other) noexcept;

    polymorphic_allocator& operator=(const polymorphic_allocator&) = delete;

    // 20.5.3.3, member functions
    Tp* allocate(size_t n);
    void deallocate(Tp* p, size_t n);
```

```
    void* allocate_bytes(size_t nbytes, size_t alignment = alignof(max_align_t));
    void deallocate_bytes(void* p, size_t nbytes, size_t alignment = alignof(max_align_t));
    template<class T> T* allocate_object(size_t n = 1);
    template<class T> void deallocate_object(T* p, size_t n = 1);
    template<class T, class... CtorArgs> T* new_object(CtorArgs&&... ctor_args);
    template<class T> void delete_object(T* p);

    template<class T, class... Args>
      void construct(T* p, Args&&... args);

    template<class T>
      void destroy(T* p);

    polymorphic_allocator select_on_container_copy_construction() const;

    memory_resource* resource() const;

    // friends
    friend bool operator==(const polymorphic_allocator& a,
                           const polymorphic_allocator& b) noexcept {
      return *a.resource() == *b.resource();
    }
  };
}
```

20.5.3.2 Constructors [mem.poly.allocator.ctor]

`polymorphic_allocator() noexcept;`

1 *Effects*: Sets `memory_rsrc` to `get_default_resource()`.

`polymorphic_allocator(memory_resource* r);`

2 *Preconditions*: `r` is non-null.

3 *Effects*: Sets `memory_rsrc` to `r`.

4 *Throws*: Nothing.

5 [*Note 1*: This constructor provides an implicit conversion from `memory_resource*`. — *end note*]

`template<class U> polymorphic_allocator(const polymorphic_allocator<U>& other) noexcept;`

6 *Effects*: Sets `memory_rsrc` to `other.resource()`.

20.5.3.3 Member functions [mem.poly.allocator.mem]

`Tp* allocate(size_t n);`

1 *Effects*: If `numeric_limits<size_t>::max() / sizeof(Tp) < n`, throws `bad_array_new_length`. Otherwise equivalent to:

```
return static_cast<Tp*>(memory_rsrc->allocate(n * sizeof(Tp), alignof(Tp)));
```

`void deallocate(Tp* p, size_t n);`

2 *Preconditions*: `p` was allocated from a memory resource `x`, equal to `*memory_rsrc`, using `x.allocate(n * sizeof(Tp), alignof(Tp))`.

3 *Effects*: Equivalent to `memory_rsrc->deallocate(p, n * sizeof(Tp), alignof(Tp))`.

4 *Throws*: Nothing.

`void* allocate_bytes(size_t nbytes, size_t alignment = alignof(max_align_t));`

5 *Effects*: Equivalent to: `return memory_rsrc->allocate(nbytes, alignment);`

6 [*Note 1*: The return type is `void*` (rather than, e.g., `byte*`) to support conversion to an arbitrary pointer type `U*` by `static_cast<U*>`, thus facilitating construction of a `U` object in the allocated memory. — *end note*]

`void deallocate_bytes(void* p, size_t nbytes, size_t alignment = alignof(max_align_t));`

7 *Effects*: Equivalent to `memory_rsrc->deallocate(p, nbytes, alignment)`.

```
template<class T>
  T* allocate_object(size_t n = 1);
```

8 *Effects*: Allocates memory suitable for holding an array of `n` objects of type `T`, as follows:

(8.1) — if `numeric_limits<size_t>::max() / sizeof(T) < n`, throws `bad_array_new_length`,

(8.2) — otherwise equivalent to:

```
return static_cast<T*>(allocate_bytes(n*sizeof(T), alignof(T)));
```

9 [*Note 2*: `T` is not deduced and must therefore be provided as a template argument. — *end note*]

```
template<class T>
  void deallocate_object(T* p, size_t n = 1);
```

10 *Effects*: Equivalent to `deallocate_bytes(p, n*sizeof(T), alignof(T))`.

```
template<class T, class... CtorArgs>
  T* new_object(CtorArgs&&... ctor_args);
```

11 *Effects*: Allocates and constructs an object of type `T`, as follows.
Equivalent to:

```
T* p = allocate_object<T>();
try {
  construct(p, std::forward<CtorArgs>(ctor_args)...);
} catch (...) {
  deallocate_object(p);
  throw;
}
return p;
```

12 [*Note 3*: `T` is not deduced and must therefore be provided as a template argument. — *end note*]

```
template<class T>
  void delete_object(T* p);
```

13 *Effects*: Equivalent to:

```
destroy(p);
deallocate_object(p);
```

```
template<class T, class... Args>
  void construct(T* p, Args&&... args);
```

14 *Mandates*: Uses-allocator construction of `T` with allocator `*this` (see 20.2.8.2) and constructor arguments `std::forward<Args>(args)...` is well-formed.

15 *Effects*: Constructs a `T` object in the storage whose address is represented by `p` by uses-allocator construction with allocator `*this` and constructor arguments `std::forward<Args>(args)...`.

16 *Throws*: Nothing unless the constructor for `T` throws.

```
template<class T>
  void destroy(T* p);
```

17 *Effects*: Equivalent to `p->~T()`.

```
polymorphic_allocator select_on_container_copy_construction() const;
```

18 *Returns*: `polymorphic_allocator()`.

19 [*Note 4*: The memory resource is not propagated. — *end note*]

```
memory_resource* resource() const;
```

20 *Returns*: `memory_rsrc`.

20.5.3.4 Equality [mem.poly.allocator.eq]

```
template<class T1, class T2>
  bool operator==(const polymorphic_allocator<T1>& a,
                  const polymorphic_allocator<T2>& b) noexcept;
```

1 *Returns*: `*a.resource() == *b.resource()`.

20.5.4 Access to program-wide `memory_resource` objects [mem.res.global]

```
memory_resource* new_delete_resource() noexcept;
```

1 *Returns*: A pointer to a static-duration object of a type derived from `memory_resource` that can serve as a resource for allocating memory using `::operator new` and `::operator delete`. The same value is returned every time this function is called. For a return value `p` and a memory resource `r`, `p->is_equal(r)` returns `&r == p`.

```
memory_resource* null_memory_resource() noexcept;
```

2 *Returns*: A pointer to a static-duration object of a type derived from `memory_resource` for which `allocate()` always throws `bad_alloc` and for which `deallocate()` has no effect. The same value is returned every time this function is called. For a return value `p` and a memory resource `r`, `p->is_equal(r)` returns `&r == p`.

3 The *default memory resource pointer* is a pointer to a memory resource that is used by certain facilities when an explicit memory resource is not supplied through the interface. Its initial value is the return value of `new_delete_resource()`.

```
memory_resource* set_default_resource(memory_resource* r) noexcept;
```

4 *Effects*: If `r` is non-null, sets the value of the default memory resource pointer to `r`, otherwise sets the default memory resource pointer to `new_delete_resource()`.

5 *Returns*: The previous value of the default memory resource pointer.

6 *Remarks*: Calling the `set_default_resource` and `get_default_resource` functions shall not incur a data race (6.10.2.2). A call to the `set_default_resource` function synchronizes with subsequent calls to the `set_default_resource` and `get_default_resource` functions.

```
memory_resource* get_default_resource() noexcept;
```

7 *Returns*: The current value of the default memory resource pointer.

20.5.5 Pool resource classes [mem.res.pool]

20.5.5.1 Classes `synchronized_pool_resource` and `unsynchronized_pool_resource` [mem.res.pool.overview]

1 The `synchronized_pool_resource` and `unsynchronized_pool_resource` classes (collectively called *pool resource classes*) are general-purpose memory resources having the following qualities:

(1.1) — Each resource frees its allocated memory on destruction, even if `deallocate` has not been called for some of the allocated blocks.

(1.2) — A pool resource consists of a collection of *pools*, serving requests for different block sizes. Each individual pool manages a collection of *chunks* that are in turn divided into blocks of uniform size, returned via calls to `do_allocate`. Each call to `do_allocate(size, alignment)` is dispatched to the pool serving the smallest blocks accommodating at least `size` bytes.

(1.3) — When a particular pool is exhausted, allocating a block from that pool results in the allocation of an additional chunk of memory from the *upstream allocator* (supplied at construction), thus replenishing the pool. With each successive replenishment, the chunk size obtained increases geometrically.

[*Note 1*: By allocating memory in chunks, the pooling strategy increases the chance that consecutive allocations will be close together in memory. — *end note*]

(1.4) — Allocation requests that exceed the largest block size of any pool are fulfilled directly from the upstream allocator.

(1.5) — A `pool_options` struct may be passed to the pool resource constructors to tune the largest block size and the maximum chunk size.

2 A `synchronized_pool_resource` may be accessed from multiple threads without external synchronization and may have thread-specific pools to reduce synchronization costs. An `unsynchronized_pool_resource` class may not be accessed from multiple threads simultaneously and thus avoids the cost of synchronization entirely in single-threaded applications.

```
namespace std::pmr {
  struct pool_options {
    size_t max_blocks_per_chunk = 0;
```

```
    size_t largest_required_pool_block = 0;
  };

  class synchronized_pool_resource : public memory_resource {
  public:
    synchronized_pool_resource(const pool_options& opts, memory_resource* upstream);

    synchronized_pool_resource()
      : synchronized_pool_resource(pool_options(), get_default_resource()) {}
    explicit synchronized_pool_resource(memory_resource* upstream)
      : synchronized_pool_resource(pool_options(), upstream) {}
    explicit synchronized_pool_resource(const pool_options& opts)
      : synchronized_pool_resource(opts, get_default_resource()) {}

    synchronized_pool_resource(const synchronized_pool_resource&) = delete;
    virtual ~synchronized_pool_resource();

    synchronized_pool_resource& operator=(const synchronized_pool_resource&) = delete;

    void release();
    memory_resource* upstream_resource() const;
    pool_options options() const;

  protected:
    void* do_allocate(size_t bytes, size_t alignment) override;
    void do_deallocate(void* p, size_t bytes, size_t alignment) override;

    bool do_is_equal(const memory_resource& other) const noexcept override;
  };

  class unsynchronized_pool_resource : public memory_resource {
  public:
    unsynchronized_pool_resource(const pool_options& opts, memory_resource* upstream);

    unsynchronized_pool_resource()
      : unsynchronized_pool_resource(pool_options(), get_default_resource()) {}
    explicit unsynchronized_pool_resource(memory_resource* upstream)
      : unsynchronized_pool_resource(pool_options(), upstream) {}
    explicit unsynchronized_pool_resource(const pool_options& opts)
      : unsynchronized_pool_resource(opts, get_default_resource()) {}

    unsynchronized_pool_resource(const unsynchronized_pool_resource&) = delete;
    virtual ~unsynchronized_pool_resource();

    unsynchronized_pool_resource& operator=(const unsynchronized_pool_resource&) = delete;

    void release();
    memory_resource* upstream_resource() const;
    pool_options options() const;

  protected:
    void* do_allocate(size_t bytes, size_t alignment) override;
    void do_deallocate(void* p, size_t bytes, size_t alignment) override;

    bool do_is_equal(const memory_resource& other) const noexcept override;
  };
}
```

20.5.5.2 `pool_options` data members [mem.res.pool.options]

1 The members of `pool_options` comprise a set of constructor options for pool resources. The effect of each option on the pool resource behavior is described below:

```
size_t max_blocks_per_chunk;
```

2 The maximum number of blocks that will be allocated at once from the upstream memory resource (20.5.6) to replenish a pool. If the value of `max_blocks_per_chunk` is zero or is greater than an implementation-defined limit, that limit is used instead. The implementation may choose to use a smaller value than is specified in this member and may use different values for different pools.

```
size_t largest_required_pool_block;
```

3 The largest allocation size that is required to be fulfilled using the pooling mechanism. Attempts to allocate a single block larger than this threshold will be allocated directly from the upstream memory resource. If `largest_required_pool_block` is zero or is greater than an implementation-defined limit, that limit is used instead. The implementation may choose a pass-through threshold larger than specified in this member.

20.5.5.3 Constructors and destructors [mem.res.pool.ctor]

```
synchronized_pool_resource(const pool_options& opts, memory_resource* upstream);
unsynchronized_pool_resource(const pool_options& opts, memory_resource* upstream);
```

1 *Preconditions*: `upstream` is the address of a valid memory resource.

2 *Effects*: Constructs a pool resource object that will obtain memory from `upstream` whenever the pool resource is unable to satisfy a memory request from its own internal data structures. The resulting object will hold a copy of `upstream`, but will not own the resource to which `upstream` points.

[*Note 1*: The intention is that in most cases there will be substantially fewer calls to `upstream->allocate()` than to `this->allocate()`. — *end note*]

The behavior of the pooling mechanism is tuned according to the value of the `opts` argument.

3 *Throws*: Nothing unless `upstream->allocate()` throws. It is unspecified if, or under what conditions, this constructor calls `upstream->allocate()`.

```
virtual ~synchronized_pool_resource();
virtual ~unsynchronized_pool_resource();
```

4 *Effects*: Calls `release()`.

20.5.5.4 Members [mem.res.pool.mem]

```
void release();
```

1 *Effects*: Calls `upstream_resource()->deallocate()` as necessary to release all allocated memory.

[*Note 1*: The memory is released back to `upstream_resource()` even if `deallocate` has not been called for some of the allocated blocks. — *end note*]

```
memory_resource* upstream_resource() const;
```

2 *Returns*: The value of the `upstream` argument provided to the constructor of this object.

```
pool_options options() const;
```

3 *Returns*: The options that control the pooling behavior of this resource. The values in the returned struct may differ from those supplied to the pool resource constructor in that values of zero will be replaced with implementation-defined defaults, and sizes may be rounded to unspecified granularity.

```
void* do_allocate(size_t bytes, size_t alignment) override;
```

4 *Effects*: If the pool selected for a block of size `bytes` is unable to satisfy the memory request from its own internal data structures, it will call `upstream_resource()->allocate()` to obtain more memory. If `bytes` is larger than that which the largest pool can handle, then memory will be allocated using `upstream_resource()->allocate()`.

5 *Returns*: A pointer to allocated storage (6.8.6.5.2) with a size of at least `bytes`. The size and alignment of the allocated memory shall meet the requirements for a class derived from `memory_resource` (20.5.2).

6 *Throws*: Nothing unless `upstream_resource()->allocate()` throws.

```
void do_deallocate(void* p, size_t bytes, size_t alignment) override;
```

7 *Effects*: Returns the memory at `p` to the pool. It is unspecified if, or under what circumstances, this operation will result in a call to `upstream_resource()->deallocate()`.

8 *Throws*: Nothing.

```
bool do_is_equal(const memory_resource& other) const noexcept override;
```

9 *Returns*: `this == &other`.

20.5.6 Class `monotonic_buffer_resource` [mem.res.monotonic.buffer]

20.5.6.1 General [mem.res.monotonic.buffer.general]

1 A `monotonic_buffer_resource` is a special-purpose memory resource intended for very fast memory allocations in situations where memory is used to build up a few objects and then is released all at once when the memory resource object is destroyed.

```
namespace std::pmr {
  class monotonic_buffer_resource : public memory_resource {
    memory_resource* upstream_rsrc;     // exposition only
    void* current_buffer;               // exposition only
    size_t next_buffer_size;            // exposition only

  public:
    explicit monotonic_buffer_resource(memory_resource* upstream);
    monotonic_buffer_resource(size_t initial_size, memory_resource* upstream);
    monotonic_buffer_resource(void* buffer, size_t buffer_size, memory_resource* upstream);

    monotonic_buffer_resource()
      : monotonic_buffer_resource(get_default_resource()) {}
    explicit monotonic_buffer_resource(size_t initial_size)
      : monotonic_buffer_resource(initial_size, get_default_resource()) {}
    monotonic_buffer_resource(void* buffer, size_t buffer_size)
      : monotonic_buffer_resource(buffer, buffer_size, get_default_resource()) {}

    monotonic_buffer_resource(const monotonic_buffer_resource&) = delete;

    virtual ~monotonic_buffer_resource();

    monotonic_buffer_resource& operator=(const monotonic_buffer_resource&) = delete;

    void release();
    memory_resource* upstream_resource() const;

  protected:
    void* do_allocate(size_t bytes, size_t alignment) override;
    void do_deallocate(void* p, size_t bytes, size_t alignment) override;

    bool do_is_equal(const memory_resource& other) const noexcept override;
  };
}
```

20.5.6.2 Constructors and destructor [mem.res.monotonic.buffer.ctor]

```
explicit monotonic_buffer_resource(memory_resource* upstream);
monotonic_buffer_resource(size_t initial_size, memory_resource* upstream);
```

1 *Preconditions*: `upstream` is the address of a valid memory resource. `initial_size`, if specified, is greater than zero.

2 *Effects*: Sets `upstream_rsrc` to `upstream` and `current_buffer` to `nullptr`. If `initial_size` is specified, sets `next_buffer_size` to at least `initial_size`; otherwise sets `next_buffer_size` to an implementation-defined size.

```
monotonic_buffer_resource(void* buffer, size_t buffer_size, memory_resource* upstream);
```

3 *Preconditions*: `upstream` is the address of a valid memory resource. `buffer_size` is no larger than the number of bytes in `buffer`.

4 *Effects*: Sets `upstream_rsrc` to `upstream`, `current_buffer` to `buffer`, and `next_buffer_size` to `buffer_size` (but not less than 1), then increases `next_buffer_size` by an implementation-defined growth factor (which need not be integral).

```
~monotonic_buffer_resource();
```

5 *Effects*: Calls `release()`.

20.5.6.3 Members [mem.res.monotonic.buffer.mem]

```
void release();
```

1 *Effects*: Calls `upstream_rsrc->deallocate()` as necessary to release all allocated memory. Resets `current_buffer` and `next_buffer_size` to their initial values at construction.

2 [*Note 1*: The memory is released back to `upstream_rsrc` even if some blocks that were allocated from `*this` have not been deallocated from `*this`. — *end note*]

```
memory_resource* upstream_resource() const;
```

3 *Returns*: The value of `upstream_rsrc`.

```
void* do_allocate(size_t bytes, size_t alignment) override;
```

4 *Effects*: If the unused space in `current_buffer` can fit a block with the specified `bytes` and `alignment`, then allocate the return block from `current_buffer`; otherwise set `current_buffer` to `upstream_rsrc->allocate(n, m)`, where `n` is not less than `max(bytes, next_buffer_size)` and `m` is not less than `alignment`, and increase `next_buffer_size` by an implementation-defined growth factor (which need not be integral), then allocate the return block from the newly-allocated `current_buffer`.

5 *Returns*: A pointer to allocated storage (6.8.6.5.2) with a size of at least `bytes`. The size and alignment of the allocated memory shall meet the requirements for a class derived from `memory_resource` (20.5.2).

6 *Throws*: Nothing unless `upstream_rsrc->allocate()` throws.

```
void do_deallocate(void* p, size_t bytes, size_t alignment) override;
```

7 *Effects*: None.

8 *Throws*: Nothing.

9 *Remarks*: Memory used by this resource increases monotonically until its destruction.

```
bool do_is_equal(const memory_resource& other) const noexcept override;
```

10 *Returns*: `this == &other`.

20.6 Class template `scoped_allocator_adaptor` [allocator.adaptor]

20.6.1 Header `<scoped_allocator>` synopsis [allocator.adaptor.syn]

```
namespace std {
  // class template scoped_allocator_adaptor
  template<class OuterAlloc, class... InnerAlloc>
    class scoped_allocator_adaptor;

  // 20.6.5, scoped allocator operators
  template<class OuterA1, class OuterA2, class... InnerAllocs>
    bool operator==(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
                    const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;
}
```

1 The class template `scoped_allocator_adaptor` is an allocator template that specifies an allocator resource (the outer allocator) to be used by a container (as any other allocator does) and also specifies an inner allocator resource to be passed to the constructor of every element within the container. This adaptor is instantiated with one outer and zero or more inner allocator types. If instantiated with only one allocator type, the inner allocator becomes the `scoped_allocator_adaptor` itself, thus using the same allocator resource for the container and every element within the container and, if the elements themselves are containers, each of their

elements recursively. If instantiated with more than one allocator, the first allocator is the outer allocator for use by the container, the second allocator is passed to the constructors of the container's elements, and, if the elements themselves are containers, the third allocator is passed to the elements' elements, and so on. If containers are nested to a depth greater than the number of allocators, the last allocator is used repeatedly, as in the single-allocator case, for any remaining recursions.

[*Note 1*: The `scoped_allocator_adaptor` is derived from the outer allocator type so it can be substituted for the outer allocator type in most expressions. — *end note*]

```
namespace std {
  template<class OuterAlloc, class... InnerAllocs>
  class scoped_allocator_adaptor : public OuterAlloc {
  private:
    using OuterTraits = allocator_traits<OuterAlloc>;   // exposition only
    scoped_allocator_adaptor<InnerAllocs...> inner;     // exposition only

  public:
    using outer_allocator_type = OuterAlloc;
    using inner_allocator_type = see below;

    using value_type           = OuterTraits::value_type;
    using size_type            = OuterTraits::size_type;
    using difference_type      = OuterTraits::difference_type;
    using pointer              = OuterTraits::pointer;
    using const_pointer        = OuterTraits::const_pointer;
    using void_pointer         = OuterTraits::void_pointer;
    using const_void_pointer   = OuterTraits::const_void_pointer;

    using propagate_on_container_copy_assignment = see below;
    using propagate_on_container_move_assignment = see below;
    using propagate_on_container_swap            = see below;
    using is_always_equal                        = see below;

    template<class Tp> struct rebind {
      using other = scoped_allocator_adaptor<
        OuterTraits::template rebind_alloc<Tp>, InnerAllocs...>;
    };

    scoped_allocator_adaptor();
    template<class OuterA2>
      scoped_allocator_adaptor(OuterA2&& outerAlloc,
                               const InnerAllocs&... innerAllocs) noexcept;

    scoped_allocator_adaptor(const scoped_allocator_adaptor& other) noexcept;
    scoped_allocator_adaptor(scoped_allocator_adaptor&& other) noexcept;

    template<class OuterA2>
      scoped_allocator_adaptor(
        const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& other) noexcept;
    template<class OuterA2>
      scoped_allocator_adaptor(
        scoped_allocator_adaptor<OuterA2, InnerAllocs...>&& other) noexcept;

    scoped_allocator_adaptor& operator=(const scoped_allocator_adaptor&) = default;
    scoped_allocator_adaptor& operator=(scoped_allocator_adaptor&&) = default;

    ~scoped_allocator_adaptor();

    inner_allocator_type& inner_allocator() noexcept;
    const inner_allocator_type& inner_allocator() const noexcept;
    outer_allocator_type& outer_allocator() noexcept;
    const outer_allocator_type& outer_allocator() const noexcept;

    pointer allocate(size_type n);
    pointer allocate(size_type n, const_void_pointer hint);
```

```
    void deallocate(pointer p, size_type n);
    size_type max_size() const;

    template<class T, class... Args>
      void construct(T* p, Args&&... args);

    template<class T>
      void destroy(T* p);

    scoped_allocator_adaptor select_on_container_copy_construction() const;
  };

  template<class OuterAlloc, class... InnerAllocs>
    scoped_allocator_adaptor(OuterAlloc, InnerAllocs...)
      -> scoped_allocator_adaptor<OuterAlloc, InnerAllocs...>;
}
```

20.6.2 Member types [allocator.adaptor.types]

```
using inner_allocator_type = see below;
```

1 *Type*: `scoped_allocator_adaptor<OuterAlloc>` if `sizeof...(InnerAllocs)` is zero; otherwise, `scoped_allocator_adaptor<InnerAllocs...>`.

```
using propagate_on_container_copy_assignment = see below;
```

2 *Type*: `true_type` if `allocator_traits<A>::propagate_on_container_copy_assignment::value` is `true` for any `A` in the set of `OuterAlloc` and `InnerAllocs...`; otherwise, `false_type`.

```
using propagate_on_container_move_assignment = see below;
```

3 *Type*: `true_type` if `allocator_traits<A>::propagate_on_container_move_assignment::value` is `true` for any `A` in the set of `OuterAlloc` and `InnerAllocs...`; otherwise, `false_type`.

```
using propagate_on_container_swap = see below;
```

4 *Type*: `true_type` if `allocator_traits<A>::propagate_on_container_swap::value` is `true` for any `A` in the set of `OuterAlloc` and `InnerAllocs...`; otherwise, `false_type`.

```
using is_always_equal = see below;
```

5 *Type*: `true_type` if `allocator_traits<A>::is_always_equal::value` is `true` for every `A` in the set of `OuterAlloc` and `InnerAllocs...`; otherwise, `false_type`.

20.6.3 Constructors [allocator.adaptor.cnstr]

```
scoped_allocator_adaptor();
```

1 *Effects*: Value-initializes the `OuterAlloc` base class and the `inner` allocator object.

```
template<class OuterA2>
  scoped_allocator_adaptor(OuterA2&& outerAlloc, const InnerAllocs&... innerAllocs) noexcept;
```

2 *Constraints*: `is_constructible_v<OuterAlloc, OuterA2>` is `true`.

3 *Effects*: Initializes the `OuterAlloc` base class with `std::forward<OuterA2>(outerAlloc)` and `inner` with `innerAllocs...` (hence recursively initializing each allocator within the adaptor with the corresponding allocator from the argument list).

```
scoped_allocator_adaptor(const scoped_allocator_adaptor& other) noexcept;
```

4 *Effects*: Initializes each allocator within the adaptor with the corresponding allocator from `other`.

```
scoped_allocator_adaptor(scoped_allocator_adaptor&& other) noexcept;
```

5 *Effects*: Move constructs each allocator within the adaptor with the corresponding allocator from `other`.

```
template<class OuterA2>
  scoped_allocator_adaptor(
    const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& other) noexcept;
```

6 *Constraints*: `is_constructible_v<OuterAlloc, const OuterA2&>` is `true`.

7 *Effects*: Initializes each allocator within the adaptor with the corresponding allocator from `other`.

```
template<class OuterA2>
  scoped_allocator_adaptor(scoped_allocator_adaptor<OuterA2, InnerAllocs...>&& other) noexcept;
```

8 *Constraints*: `is_constructible_v<OuterAlloc, OuterA2>` is `true`.

9 *Effects*: Initializes each allocator within the adaptor with the corresponding allocator rvalue from `other`.

20.6.4 Members [allocator.adaptor.members]

1 In the `construct` member functions, *OUTERMOST*`(x)` is *OUTERMOST*`(x.outer_allocator())` if the expression `x.outer_allocator()` is valid (13.10.3) and `x` otherwise; *OUTERMOST_ALLOC_TRAITS*`(x)` is `allocator_traits<remove_reference_t<decltype(`*OUTERMOST*`(x))>>`.

[*Note 1*: *OUTERMOST*`(x)` and *OUTERMOST_ALLOC_TRAITS*`(x)` are recursive operations. It is incumbent upon the definition of `outer_allocator()` to ensure that the recursion terminates. It will terminate for all instantiations of `scoped_allocator_adaptor`. — *end note*]

```
inner_allocator_type& inner_allocator() noexcept;
const inner_allocator_type& inner_allocator() const noexcept;
```

2 *Returns*: `*this` if `sizeof...(InnerAllocs)` is zero; otherwise, `inner`.

```
outer_allocator_type& outer_allocator() noexcept;
```

3 *Returns*: `static_cast<OuterAlloc&>(*this)`.

```
const outer_allocator_type& outer_allocator() const noexcept;
```

4 *Returns*: `static_cast<const OuterAlloc&>(*this)`.

```
pointer allocate(size_type n);
```

5 *Returns*: `allocator_traits<OuterAlloc>::allocate(outer_allocator(), n)`.

```
pointer allocate(size_type n, const_void_pointer hint);
```

6 *Returns*: `allocator_traits<OuterAlloc>::allocate(outer_allocator(), n, hint)`.

```
void deallocate(pointer p, size_type n) noexcept;
```

7 *Effects*: As if by: `allocator_traits<OuterAlloc>::deallocate(outer_allocator(), p, n);`

```
size_type max_size() const;
```

8 *Returns*: `allocator_traits<OuterAlloc>::max_size(outer_allocator())`.

```
template<class T, class... Args>
  void construct(T* p, Args&&... args);
```

9 *Effects*: Equivalent to:

```
apply([p, this](auto&&... newargs) {
        OUTERMOST_ALLOC_TRAITS(*this)::construct(
          OUTERMOST(*this), p,
          std::forward<decltype(newargs)>(newargs)...);
      },
      uses_allocator_construction_args<T>(inner_allocator(),
                                          std::forward<Args>(args)...));
```

```
template<class T>
  void destroy(T* p);
```

10 *Effects*: Calls *OUTERMOST_ALLOC_TRAITS*`(*this)::destroy(`*OUTERMOST*`(*this), p)`.

```
scoped_allocator_adaptor select_on_container_copy_construction() const;
```

11 *Returns*: A new `scoped_allocator_adaptor` object where each allocator `a1` within the adaptor is initialized with `allocator_traits<A1>::select_on_container_copy_construction(a2)`, where `A1` is the type of `a1` and `a2` is the corresponding allocator in `*this`.

20.6.5 Operators [scoped.adaptor.operators]

```
template<class OuterA1, class OuterA2, class... InnerAllocs>
  bool operator==(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
                  const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;
```

1 *Returns*: If `sizeof...(InnerAllocs)` is zero,

```
a.outer_allocator() == b.outer_allocator()
```

otherwise

```
a.outer_allocator() == b.outer_allocator() && a.inner_allocator() == b.inner_allocator()
```

21 Metaprogramming library [meta]

21.1 General [meta.general]

1 This Clause describes metaprogramming facilities. These facilities are summarized in Table 51.

Table 51 — Metaprogramming library summary [tab:meta.summary]

	Subclause	Header
21.2	Integer sequences	`<utility>`
21.3	Type traits	`<type_traits>`
21.4	Reflection	`<meta>`
21.5	Rational arithmetic	`<ratio>`

21.2 Compile-time integer sequences [intseq]

21.2.1 General [intseq.general]

1 The library provides a class template that can represent an integer sequence. When used as an argument to a function template the template parameter pack defining the sequence can be deduced and used in a pack expansion.

[*Note 1*: The `index_sequence` alias template is provided for the common case of an integer sequence of type `size_t`; see also 22.4.6. — *end note*]

21.2.2 Class template `integer_sequence` [intseq.intseq]

```
namespace std {
  template<class T, T... I> struct integer_sequence {
    using value_type = T;
    static constexpr size_t size() noexcept { return sizeof...(I); }
  };
}
```

1 *Mandates*: `T` is an integer type.

21.2.3 Alias template `make_integer_sequence` [intseq.make]

```
template<class T, T N>
  using make_integer_sequence = integer_sequence<T, see below>;
```

1 *Mandates*: `N` ≥ 0.

2 The alias template `make_integer_sequence` denotes a specialization of `integer_sequence` with `N` constant template arguments. The type `make_integer_sequence<T, N>` is an alias for the type `integer_sequence<T, 0, 1, ..., N - 1>`.

[*Note 1*: `make_integer_sequence<int, 0>` is an alias for the type `integer_sequence<int>`. — *end note*]

21.2.4 Structured binding support [intseq.binding]

```
template<class T, T... Values>
  struct tuple_size<integer_sequence<T, Values...>>
    : integral_constant<size_t, sizeof...(Values)> { };

template<size_t I, class T, T... Values>
  struct tuple_element<I, integer_sequence<T, Values...>> {
    using type = T;
  };
template<size_t I, class T, T... Values>
  struct tuple_element<I, const integer_sequence<T, Values...>> {
    using type = T;
```

©ISO/IEC

```
};
```

1 *Mandates*: `I < sizeof...(Values)`.

```
template<size_t I, class T, T... Values>
  constexpr T get(integer_sequence<T, Values...>) noexcept;
```

2 *Mandates*: `I < sizeof...(Values)`.

3 *Returns*: `Values...[I]`.

21.3 Metaprogramming and type traits [type.traits]

21.3.1 General [type.traits.general]

1 Subclause 21.3 describes components used by C++ programs, particularly in templates, to support the widest possible range of types, optimize template code usage, detect type related user errors, and perform type inference and transformation at compile time. It includes type classification traits, type property inspection traits, and type transformations. The type classification traits describe a complete taxonomy of all possible C++ types, and state where in that taxonomy a given type belongs. The type property inspection traits allow important characteristics of types or of combinations of types to be inspected. The type transformations allow certain properties of types to be manipulated.

2 All functions specified in 21.3 are signal-safe (17.14.5).

21.3.2 Requirements [meta.rqmts]

1 A *Cpp17UnaryTypeTrait* describes a property of a type. It shall be a class template that takes one template type argument and, optionally, additional arguments that help define the property being described. It shall be *Cpp17DefaultConstructible*, *Cpp17CopyConstructible*, and publicly and unambiguously derived, directly or indirectly, from its *base characteristic*, which is a specialization of the template `integral_constant` (21.3.4), with the arguments to the template `integral_constant` determined by the requirements for the particular property being described. The member names of the base characteristic shall not be hidden and shall be unambiguously available in the *Cpp17UnaryTypeTrait*.

2 A *Cpp17BinaryTypeTrait* describes a relationship between two types. It shall be a class template that takes two template type arguments and, optionally, additional arguments that help define the relationship being described. It shall be *Cpp17DefaultConstructible*, *Cpp17CopyConstructible*, and publicly and unambiguously derived, directly or indirectly, from its *base characteristic*, which is a specialization of the template `integral_constant` (21.3.4), with the arguments to the template `integral_constant` determined by the requirements for the particular relationship being described. The member names of the base characteristic shall not be hidden and shall be unambiguously available in the *Cpp17BinaryTypeTrait*.

3 A *Cpp17TransformationTrait* modifies a property of a type. It shall be a class template that takes one template type argument and, optionally, additional arguments that help define the modification. It shall declare a publicly accessible nested type named `type`, which shall be a synonym for the modified type.

4 Unless otherwise specified, the behavior of a program that adds specializations for any of the templates specified in 21.3 is undefined.

5 Unless otherwise specified, an incomplete type may be used to instantiate a template specified in 21.3. The behavior of a program is undefined if

(5.1) — an instantiation of a template specified in 21.3 directly or indirectly depends on an incompletely-defined object type `T`, and

(5.2) — that instantiation could yield a different result were `T` hypothetically completed.

21.3.3 Header `<type_traits>` synopsis [meta.type.synop]

```
// all freestanding
namespace std {
  // 21.3.4, helper class
  template<class T, T v> struct integral_constant;

  template<bool B>
    using bool_constant = integral_constant<bool, B>;
  using true_type  = bool_constant<true>;
  using false_type = bool_constant<false>;
```

}
```

21.3.4 Helper classes [meta.help]

```
namespace std {
  template<class T, T v> struct integral_constant {
    static constexpr T value = v;

    using value_type = T;
    using type = integral_constant<T, v>;

    constexpr operator value_type() const noexcept { return value; }
    constexpr value_type operator()() const noexcept { return value; }
  };
}
```

1 The class template `integral_constant`, alias template `bool_constant`, and its associated *typedef-name*s `true_type` and `false_type` are used as base classes to define the interface for various type traits.

21.3.5 Unary type traits [meta.unary]

21.3.5.1 General [meta.unary.general]

1 Subclause 21.3.5 contains templates that may be used to query the properties of a type at compile time.

2 Each of these templates shall be a *Cpp17UnaryTypeTrait* (21.3.2) with a base characteristic of `true_type` if the corresponding condition is `true`, otherwise `false_type`.

21.3.5.2 Primary type categories [meta.unary.cat]

1 The primary type categories specified in Table 52 correspond to the descriptions given in subclause 6.9 of the C++ standard.

2 For any given type `T`, the result of applying one of these templates to `T` and to *cv* `T` shall yield the same result.

3 [*Note 1*: For any given type `T`, exactly one of the primary type categories has a `value` member that evaluates to `true`. — *end note*]

Table 52 — Primary type category predicates [tab:meta.unary.cat]

Template	Condition	Comments
`template<class T> struct is_void;`	`T` is `void`	
`template<class T> struct is_null_pointer;`	`T` is `nullptr_t` (6.9.2)	
`template<class T> struct is_integral;`	`T` is an integral type (6.9.2)	
`template<class T> struct is_floating_point;`	`T` is a floating-point type (6.9.2)	
`template<class T> struct is_array;`	`T` is an array type (6.9.4) of known or unknown extent	Class template `array` (23.3.3) is not an array type.
`template<class T> struct is_pointer;`	`T` is a pointer type (6.9.4)	Includes pointers to functions but not pointers to non-static members.
`template<class T> struct is_lvalue_reference;`	`T` is an lvalue reference type (9.3.4.3)	
`template<class T> struct is_rvalue_reference;`	`T` is an rvalue reference type (9.3.4.3)	
`template<class T> struct is_member_object_pointer;`	`T` is a pointer to data member	
`template<class T> struct is_member_function_pointer;`	`T` is a pointer to member function	
`template<class T> struct is_enum;`	`T` is an enumeration type (6.9.4)	
`template<class T> struct is_union;`	`T` is a union type (6.9.4)	
`template<class T> struct is_class;`	`T` is a non-union class type (6.9.4)	
`template<class T> struct is_function;`	`T` is a function type (6.9.4)	

Table 52 — Primary type category predicates (continued)

Template	Condition	Comments
`template<class T>` `struct is_reflection;`	`T` is `std::meta::info` (6.9.2)	

21.3.5.3 Composite type traits [meta.unary.comp]

1 The templates specified in Table 53 provide convenient compositions of the primary type categories, corresponding to the descriptions given in subclause 6.9.

2 For any given type `T`, the result of applying one of these templates to `T` and to *cv* `T` shall yield the same result.

Table 53 — Composite type category predicates [tab:meta.unary.comp]

Template	Condition	Comments
`template<class T>` `struct is_reference;`	`T` is an lvalue reference or an rvalue reference	
`template<class T>` `struct is_arithmetic;`	`T` is an arithmetic type (6.9.2)	
`template<class T>` `struct is_fundamental;`	`T` is a fundamental type (6.9.2)	
`template<class T>` `struct is_object;`	`T` is an object type (6.9.1)	
`template<class T>` `struct is_scalar;`	`T` is a scalar type (6.9.1)	
`template<class T>` `struct is_compound;`	`T` is a compound type (6.9.4)	
`template<class T>` `struct is_member_pointer;`	`T` is a pointer-to-member type (6.9.4)	

21.3.5.4 Type properties [meta.unary.prop]

1 The templates specified in Table 54 provide access to some of the more important properties of types.

2 It is unspecified whether the library defines any full or partial specializations of any of these templates.

3 For all of the class templates `X` declared in this subclause, instantiating that template with a template-argument that is a class template specialization may result in the implicit instantiation of the template argument if and only if the semantics of `X` require that the argument is a complete type.

4 For the purpose of defining the templates in this subclause, a function call expression `declval<T>()` for any type `T` is considered to be a trivial (D.13, 11.4.4) function call that is not an odr-use (6.3) of `declval` in the context of the corresponding definition notwithstanding the restrictions of 22.2.6.

5 For the purpose of defining the templates in this subclause, let *`VAL`*`<T>` for some type `T` be an expression defined as follows:

(5.1) — If `T` is a reference or function type, *`VAL`*`<T>` is an expression with the same type and value category as `declval<T>()`.

(5.2) — Otherwise, *`VAL`*`<T>` is a prvalue that initially has type `T`.

[*Note 1*: If `T` is cv-qualified, the cv-qualification is subject to adjustment (7.2.2). — *end note*]

Table 54 — Type property predicates [tab:meta.unary.prop]

Template	Condition	Preconditions
`template<class T> struct is_const;`	`T` is const-qualified (6.9.5)	
`template<class T> struct is_volatile;`	`T` is volatile-qualified (6.9.5)	
`template<class T> struct is_trivially_copyable;`	`T` is a trivially copyable type (6.9.1)	`remove_all_extents_t<T>` shall be a complete type or *cv* `void`.
`template<class T> struct is_standard_layout;`	`T` is a standard-layout type (6.9.1)	`remove_all_extents_t<T>` shall be a complete type or *cv* `void`.
`template<class T> struct is_empty;`	`T` is a class type, but not a union type, with no non-static data members other than subobjects of zero size, no virtual member functions, no virtual base classes, and no base class `B` for which `is_empty_v<B>` is `false`.	If `T` is a non-union class type, `T` shall be a complete type.
`template<class T> struct is_polymorphic;`	`T` is a polymorphic class (11.7.3)	If `T` is a non-union class type, `T` shall be a complete type.
`template<class T> struct is_abstract;`	`T` is an abstract class (11.7.4)	If `T` is a non-union class type, `T` shall be a complete type.
`template<class T> struct is_final;`	`T` is a class type marked with the *class-property-specifier* `final` (11.1). [*Note 2*: A union is a class type that can be marked with `final`. — *end note*]	If `T` is a class type, `T` shall be a complete type.
`template<class T> struct is_aggregate;`	`T` is an aggregate type (9.5.2)	`T` shall be an array type, a complete type, or *cv* `void`.
`template<class T> struct is_structural;`	`T` is a structural type (13.2)	`remove_all_extents_t<T>` shall be a complete type or *cv* `void`.
`template<class T> struct is_signed;`	If `is_arithmetic_v<T>` is `true`, the same result as `T(-1) < T(0)`; otherwise, `false`	
`template<class T> struct is_unsigned;`	If `is_arithmetic_v<T>` is `true`, the same result as `T(0) < T(-1)`; otherwise, `false`	
`template<class T> struct is_bounded_array;`	`T` is an array type of known bound (9.3.4.5)	
`template<class T> struct is_unbounded_array;`	`T` is an array type of unknown bound (9.3.4.5)	
`template<class T> struct is_scoped_enum;`	`T` is a scoped enumeration (9.8.1)	

Table 54 — Type property predicates (continued)

Template	Condition	Preconditions
`template<class T, class... Args>` `struct is_constructible;`	For a function type `T` or for a *cv* `void` type `T`, `is_constructible_v<T, Args...>` is `false`, otherwise *see below*	`T` and all types in the template parameter pack `Args` shall be complete types, *cv* `void`, or arrays of unknown bound.
`template<class T>` `struct is_default_constructible;`	`is_constructible_v<T>` is `true`.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.
`template<class T>` `struct is_copy_constructible;`	For a referenceable type `T` (3.46), the same result as `is_constructible_v<T, const T&>`, otherwise `false`.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.
`template<class T>` `struct is_move_constructible;`	For a referenceable type `T`, the same result as `is_constructible_v<T, T&&>`, otherwise `false`.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.
`template<class T, class U>` `struct is_assignable;`	The expression `declval<T>() = declval<U>()` is well-formed when treated as an unevaluated operand (7.2.3). Access checking is performed as if in a context unrelated to `T` and `U`. Only the validity of the immediate context of the assignment expression is considered. [*Note 3*: The compilation of the expression can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the "immediate context" and can result in the program being ill-formed. — *end note*]	`T` and `U` shall be complete types, *cv* `void`, or arrays of unknown bound.
`template<class T>` `struct is_copy_assignable;`	For a referenceable type `T`, the same result as `is_assignable_v<T&, const T&>`, otherwise `false`.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.
`template<class T>` `struct is_move_assignable;`	For a referenceable type `T`, the same result as `is_assignable_v<T&, T&&>`, otherwise `false`.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.

©ISO/IEC

Table 54 — Type property predicates (continued)

Template	Condition	Preconditions
`template<class T, class U>` `struct is_swappable_with;`	The expressions `swap(declval<T>(), declval<U>())` and `swap(declval<U>(), declval<T>())` are each well-formed when treated as an unevaluated operand (7.2.3) in an overload-resolution context for swappable values (16.4.4.3). Access checking is performed as if in a context unrelated to `T` and `U`. Only the validity of the immediate context of the `swap` expressions is considered. [*Note 4*: The compilation of the expressions can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the "immediate context" and can result in the program being ill-formed. — *end note*]	`T` and `U` shall be complete types, *cv* `void`, or arrays of unknown bound.
`template<class T>` `struct is_swappable;`	For a referenceable type `T`, the same result as `is_swappable_with_v<T&, T&>`, otherwise `false`.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.
`template<class T>` `struct is_destructible;`	Either `T` is a reference type, or `T` is a complete object type for which the expression `declval<U&>().~U()` is well-formed when treated as an unevaluated operand (7.2.3), where `U` is `remove_all_extents_t<T>`.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.
`template<class T, class... Args>` `struct is_trivially_constructible;`	`is_constructible_v<T, Args...>` is `true` and the variable definition for `is_constructible`, as defined below, is known to call no operation that is not trivial (D.13, 11.4.4).	`T` and all types in the template parameter pack `Args` shall be complete types, *cv* `void`, or arrays of unknown bound.
`template<class T>` `struct is_trivially_default_constructible;`	`is_trivially_constructible_v<T>` is `true`.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.

©ISO/IEC

Table 54 — Type property predicates (continued)

Template	Condition	Preconditions
`template<class T> struct is_trivially_copy_constructible;`	For a referenceable type `T`, the same result as `is_trivially_constructible_v<T, const T&>`, otherwise `false`.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.
`template<class T> struct is_trivially_move_constructible;`	For a referenceable type `T`, the same result as `is_trivially_constructible_v<T, T&&>`, otherwise `false`.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.
`template<class T, class U> struct is_trivially_assignable;`	`is_assignable_v<T, U>` is `true` and the assignment, as defined by `is_assignable`, is known to call no operation that is not trivial (D.13, 11.4.4).	`T` and `U` shall be complete types, *cv* `void`, or arrays of unknown bound.
`template<class T> struct is_trivially_copy_assignable;`	For a referenceable type `T`, the same result as `is_trivially_assignable_v<T&, const T&>`, otherwise `false`.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.
`template<class T> struct is_trivially_move_assignable;`	For a referenceable type `T`, the same result as `is_trivially_assignable_v<T&, T&&>`, otherwise `false`.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.
`template<class T> struct is_trivially_destructible;`	`is_destructible_v<T>` is `true` and `remove_all_extents_t<T>` is either a non-class type or a class type with a trivial destructor.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.
`template<class T, class... Args> struct is_nothrow_constructible;`	`is_constructible_v<T, Args...>` is `true` and the variable definition for `is_constructible`, as defined below, is known not to throw any exceptions (7.6.2.7).	`T` and all types in the template parameter pack `Args` shall be complete types, *cv* `void`, or arrays of unknown bound.
`template<class T> struct is_nothrow_default_constructible;`	`is_nothrow_constructible_v<T>` is `true`.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.
`template<class T> struct is_nothrow_copy_constructible;`	For a referenceable type `T`, the same result as `is_nothrow_constructible_v<T, const T&>`, otherwise `false`.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.
`template<class T> struct is_nothrow_move_constructible;`	For a referenceable type `T`, the same result as `is_nothrow_constructible_v<T, T&&>`, otherwise `false`.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.

Table 54 — Type property predicates (continued)

Template	Condition	Preconditions
`template<class T, class U> struct is_nothrow_assignable;`	`is_assignable_v<T, U>` is `true` and the assignment is known not to throw any exceptions (7.6.2.7).	`T` and `U` shall be complete types, *cv* `void`, or arrays of unknown bound.
`template<class T> struct is_nothrow_copy_assignable;`	For a referenceable type `T`, the same result as `is_nothrow_assignable_v<T&, const T&>`, otherwise `false`.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.
`template<class T> struct is_nothrow_move_assignable;`	For a referenceable type `T`, the same result as `is_nothrow_assignable_v<T&, T&&>`, otherwise `false`.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.
`template<class T, class U> struct is_nothrow_swappable_with;`	`is_swappable_with_v<T, U>` is `true` and each `swap` expression of the definition of `is_swappable_with<T, U>` is known not to throw any exceptions (7.6.2.7).	`T` and `U` shall be complete types, *cv* `void`, or arrays of unknown bound.
`template<class T> struct is_nothrow_swappable;`	For a referenceable type `T`, the same result as `is_nothrow_swappable_with_v<T&, T&>`, otherwise `false`.	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.
`template<class T> struct is_nothrow_destructible;`	`is_destructible_v<T>` is `true` and the indicated destructor is known not to throw any exceptions (7.6.2.7).	`T` shall be a complete type, *cv* `void`, or an array of unknown bound.
`template<class T> struct is_implicit_lifetime;`	`T` is an implicit-lifetime type (6.9.1).	`T` shall be an array type, a complete type, or *cv* `void`.
`template<class T> struct has_virtual_destructor;`	`T` has a virtual destructor (11.4.7)	If `T` is a non-union class type, `T` shall be a complete type.
`template<class T> struct has_unique_object_representations;`	For an array type `T`, the same result as `has_unique_object_representations_v<remove_all_extents_t<T>>`, otherwise *see below*.	`remove_all_extents_t<T>` shall be a complete type or *cv* `void`.

©ISO/IEC

Table 54 — Type property predicates (continued)

Template	Condition	Preconditions
`template<class T, class U>` `struct reference_constructs_from_-` `temporary;`	`T` is a reference type, and the initialization `T t(`*`VAL`*`<U>);` is well-formed and binds `t` to a temporary object whose lifetime is extended (6.8.7). The full-expression of the variable initialization is treated as an unevaluated operand (7.2.3). Access checking is performed as if in a context unrelated to `T` and `U`. Only the validity of the immediate context of the variable initialization is considered. [*Note 5*: The initialization can result in effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such effects are not in the "immediate context" and can result in the program being ill-formed. — *end note*]	`T` and `U` shall be complete types, *cv* `void`, or arrays of unknown bound.

Table 54 — Type property predicates (continued)

Template	Condition	Preconditions
`template<class T, class U>` `struct` `reference_converts_from_temporary;`	`T` is a reference type, and the initialization `T t = VAL<U>;` is well-formed and binds `t` to a temporary object whose lifetime is extended (6.8.7). The full-expression of the variable initialization is treated as an unevaluated operand (7.2.3). Access checking is performed as if in a context unrelated to `T` and `U`. Only the validity of the immediate context of the variable initialization is considered. [*Note 6*: The initialization can result in effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such effects are not in the "immediate context" and can result in the program being ill-formed. — *end note*]	`T` and `U` shall be complete types, *cv* `void`, or arrays of unknown bound.

6 [*Example 1*:

```
is_const_v<const volatile int>      // true
is_const_v<const int*>              // false
is_const_v<const int&>              // false
is_const_v<int[3]>                  // false
is_const_v<const int[3]>            // true
```

— *end example*]

7 [*Example 2*:

```
remove_const_t<const volatile int>  // volatile int
remove_const_t<const int* const>    // const int*
remove_const_t<const int&>          // const int&
remove_const_t<const int[3]>        // int[3]
```

— *end example*]

8 [*Example 3*:

```
// Given:
struct P final { };
union U1 { };
union U2 final { };

// the following assertions hold:
static_assert(!is_final_v<int>);
static_assert(is_final_v<P>);
static_assert(!is_final_v<U1>);
static_assert(is_final_v<U2>);
```

— *end example*]

9 The predicate condition for a template specialization `is_constructible<T, Args...>` shall be satisfied if and only if the following variable definition would be well-formed for some invented variable `t`:

```
T t(declval<Args>()...);
```

[*Note 7*: These tokens are never interpreted as a function declaration. — *end note*]

The full-expression of the variable initialization is treated as an unevaluated operand (7.2.3). Access checking is performed as if in a context unrelated to `T` and any of the `Args`. Only the validity of the immediate context of the variable initialization is considered.

[*Note 8*: The evaluation of the initialization can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the "immediate context" and can result in the program being ill-formed. — *end note*]

10 The predicate condition for a template specialization `has_unique_object_representations<T>` shall be satisfied if and only if

(10.1) — `T` is trivially copyable, and

(10.2) — any two objects of type `T` with the same value have the same object representation, where

(10.2.1) — two objects of array or non-union class type are considered to have the same value if their respective sequences of direct subobjects have the same values, and

(10.2.2) — two objects of union type are considered to have the same value if they have the same active member and the corresponding members have the same value.

The set of scalar types for which this condition holds is implementation-defined.

[*Note 9*: If a type has padding bits, the condition does not hold; otherwise, the condition holds true for integral types. — *end note*]

21.3.6 Type property queries [meta.unary.prop.query]

1 The templates specified in Table 55 may be used to query properties of types at compile time.

Table 55 — Type property queries [tab:meta.unary.prop.query]

Template	Value
`template<class T>` `struct alignment_of;`	`alignof(T)`. *Mandates*: `alignof(T)` is a valid expression (7.6.2.6)
`template<class T>` `struct rank;`	If `T` is an array type, an integer value representing the number of dimensions of `T`; otherwise, 0.
`template<class T,` `unsigned I = 0>` `struct extent;`	If `T` is not an array type, or if it has rank less than or equal to `I`, or if `I` is 0 and `T` has type "array of unknown bound of `U`", then 0; otherwise, the bound (9.3.4.5) of the `I`$^{\text{th}}$ dimension of `T`, where indexing of `I` is zero-based

2 Each of these templates shall be a *Cpp17UnaryTypeTrait* (21.3.2) with a base characteristic of `integral_constant<size_t, Value>`.

3 [*Example 1*:

```
// the following assertions hold:
static_assert(rank_v<int> == 0);
static_assert(rank_v<int[2]> == 1);
static_assert(rank_v<int[][4]> == 2);
```

— *end example*]

4 [*Example 2*:

```
// the following assertions hold:
static_assert(extent_v<int> == 0);
static_assert(extent_v<int[2]> == 2);
static_assert(extent_v<int[2][4]> == 2);
static_assert(extent_v<int[][4]> == 0);
static_assert(extent_v<int, 1> == 0);
static_assert(extent_v<int[2], 1> == 0);
```

```
static_assert(extent_v<int[2][4], 1> == 4);
static_assert(extent_v<int[][4], 1> == 4);
```

— *end example*]

21.3.7 Relationships between types [meta.rel]

1 The templates specified in Table 56 may be used to query relationships between types at compile time.

2 Each of these templates shall be a *Cpp17BinaryTypeTrait* (21.3.2) with a base characteristic of `true_type` if the corresponding condition is true, otherwise `false_type`.

3 Let *ELEMS-OF*(T) be the parameter pack `get<N>(declval<T>())`, where *N* is the pack of `size_t` template arguments of the specialization of `index_sequence` denoted by `make_index_sequence<tuple_size_v<remove_reference_t<T>>>`.

Table 56 — Type relationship predicates [tab:meta.rel]

Template	Condition	Comments
`template<class T, class U> struct is_same;`	`T` and `U` name the same type with the same cv-qualifications	
`template<class Base, class Derived> struct is_base_of;`	`Base` is a base class of `Derived` (11.7) without regard to cv-qualifiers or `Base` and `Derived` are not unions and name the same class type without regard to cv-qualifiers	If `Base` and `Derived` are non-union class types and are not (possibly cv-qualified versions of) the same type, `Derived` shall be a complete type. [*Note 1*: Base classes that are private, protected, or ambiguous are, nonetheless, base classes. — *end note*]
`template<class Base, class Derived> struct is_virtual_base_of;`	`Base` is a virtual base class of `Derived` (11.7.2) without regard to cv-qualifiers.	If `Base` and `Derived` are non-union class types, `Derived` shall be a complete type. [*Note 2*: Virtual base classes that are private, protected, or ambiguous are, nonetheless, virtual base classes. — *end note*] [*Note 3*: A class is never a virtual base class of itself. — *end note*]
`template<class From, class To> struct is_convertible;`	*see below*	`From` and `To` shall be complete types, *cv* `void`, or arrays of unknown bound.
`template<class From, class To> struct is_nothrow_convertible;`	`is_convertible_v<From, To>` is `true` and the conversion, as defined by `is_convertible`, is known not to throw any exceptions (7.6.2.7)	`From` and `To` shall be complete types, *cv* `void`, or arrays of unknown bound.
`template<class T, class U> struct is_layout_compatible;`	`T` and `U` are layout-compatible (6.9.1)	`T` and `U` shall be complete types, *cv* `void`, or arrays of unknown bound.

Table 56 — Type relationship predicates (continued)

Template	Condition	Comments
`template<class Base, class Derived> struct is_pointer_interconvertible_base_of;`	`Derived` is unambiguously derived from `Base` without regard to cv-qualifiers, and each object of type `Derived` is pointer-interconvertible (6.9.4) with its `Base` subobject, or `Base` and `Derived` are not unions and name the same class type without regard to cv-qualifiers.	If `Base` and `Derived` are non-union class types and are not (possibly cv-qualified versions of) the same type, `Derived` shall be a complete type.
`template<class Fn, class... ArgTypes> struct is_invocable;`	The expression *INVOKE*`(declval<Fn>(), declval<ArgTypes>()...)` (22.10.4) is well-formed when treated as an unevaluated operand (7.2.3)	`Fn` and all types in the template parameter pack `ArgTypes` shall be complete types, *cv* `void`, or arrays of unknown bound.
`template<class R, class Fn, class... ArgTypes> struct is_invocable_r;`	The expression *INVOKE*`<R>(declval<Fn>(), declval<ArgTypes>()...)` is well-formed when treated as an unevaluated operand	`Fn`, `R`, and all types in the template parameter pack `ArgTypes` shall be complete types, *cv* `void`, or arrays of unknown bound.
`template<class Fn, class... ArgTypes> struct is_nothrow_invocable;`	`is_invocable_v< Fn, ArgTypes...>` is `true` and the expression *INVOKE*`(declval<Fn>(), declval<ArgTypes>()...)` is known not to throw any exceptions (7.6.2.7)	`Fn` and all types in the template parameter pack `ArgTypes` shall be complete types, *cv* `void`, or arrays of unknown bound.
`template<class R, class Fn, class... ArgTypes> struct is_nothrow_invocable_r;`	`is_invocable_r_v< R, Fn, ArgTypes...>` is `true` and the expression *INVOKE*`<R>(declval<Fn>(), declval<ArgTypes>()...)` is known not to throw any exceptions (7.6.2.7)	`Fn`, `R`, and all types in the template parameter pack `ArgTypes` shall be complete types, *cv* `void`, or arrays of unknown bound.
`template<class Fn, class Tuple> struct is_applicable;`	*tuple-like*`<Tuple>` is `true` and the expression *INVOKE*`(declval<Fn>(), `*ELEMS-OF*`(Tuple)...)` is well-formed when treated as an unevaluated operand.	`Fn` and `Tuple` shall be complete types, *cv* `void`, or arrays of unknown bound.
`template<class Fn, class Tuple> struct is_nothrow_applicable;`	`is_applicable_v< Fn, Tuple>` is `true` and the expression *INVOKE*`(declval<Fn>(), `*ELEMS-OF*`(Tuple)...)` is known not to throw any exceptions (7.6.2.7).	`Fn` and `Tuple` shall be complete types, *cv* `void`, or arrays of unknown bound.

4 For the purpose of defining the templates in this subclause, a function call expression `declval<T>()` for any type `T` is considered to be a trivial (D.13, 11.4.4) function call that is not an odr-use (6.3) of `declval` in the context of the corresponding definition notwithstanding the restrictions of 22.2.6.

5 [*Example 1*:

```
struct B {};
struct B1 : B {};
```

```
struct B2 : B {};
struct D : private B1, private B2 {};

is_base_of_v<B, D>              // true
is_base_of_v<const B, D>        // true
is_base_of_v<B, const D>        // true
is_base_of_v<B, const B>        // true
is_base_of_v<D, B>              // false
is_base_of_v<B&, D&>            // false
is_base_of_v<B[3], D[3]>        // false
is_base_of_v<int, int>          // false
```

— *end example*]

6 The predicate condition for a template specialization `is_convertible<From, To>` shall be satisfied if and only if the return statement (8.8.4) in the following code would be well-formed, including any implicit conversions to the return type of the function:

```
To test() {
  return declval<From>();
}
```

[*Note 4*: This requirement gives well-defined results for reference types, array types, function types, and *cv* `void`. — *end note*]

Access checking is performed in a context unrelated to `To` and `From`. The operand of the `return` statement (including initialization of the returned object or reference, if any) is treated as an unevaluated operand (7.2.3), and only the validity of its immediate context is considered.

[*Note 5*: The initialization can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the "immediate context" and can result in the program being ill-formed. — *end note*]

21.3.8 Transformations between types [meta.trans]

21.3.8.1 General [meta.trans.general]

1 Subclause 21.3.8 contains templates that may be used to transform one type to another following some predefined rule.

2 Each of the templates in 21.3.8 shall be a *Cpp17TransformationTrait* (21.3.2).

21.3.8.2 Const-volatile modifications [meta.trans.cv]

1 The templates specified in Table 57 add or remove cv-qualifications (6.9.5).

Table 57 — Const-volatile modifications [tab:meta.trans.cv]

Template	Comments
`template<class T>` `struct remove_const;`	The member typedef `type` denotes the type formed by removing any top-level const-qualifier from `T`. [*Example 1*: `remove_const_t<const volatile int>` evaluates to `volatile int`, whereas `remove_const_t<const int*>` evaluates to `const int*`. — *end example*]
`template<class T>` `struct remove_volatile;`	The member typedef `type` denotes the type formed by removing any top-level volatile-qualifier from `T`. [*Example 2*: `remove_volatile_t<const volatile int>` evaluates to `const int`, whereas `remove_volatile_t<volatile int*>` evaluates to `volatile int*`. — *end example*]
`template<class T>` `struct remove_cv;`	The member typedef `type` denotes the type formed by removing any top-level cv-qualifiers from `T`. [*Example 3*: `remove_cv_t<const volatile int>` evaluates to `int`, whereas `remove_cv_t<const volatile int*>` evaluates to `const volatile int*`. — *end example*]
`template<class T>` `struct add_const;`	The member typedef `type` denotes `const T`. [*Note 1*: `const` has no effect when `T` is a reference, function, or top-level const-qualified type. — *end note*]

Table 57 — Const-volatile modifications (continued)

Template	Comments
`template<class T>` `struct add_volatile;`	The member typedef `type` denotes `volatile T`. [*Note 2*: `volatile` has no effect when `T` is a reference, function, or top-level volatile-qualified type. — *end note*]
`template<class T>` `struct add_cv;`	The member typedef `type` denotes `add_const_t<add_volatile_t<T>>`.

21.3.8.3 Reference modifications [meta.trans.ref]

1 The templates specified in Table 58 add or remove references.

Table 58 — Reference modifications [tab:meta.trans.ref]

Template	Comments
`template<class T>` `struct remove_reference;`	If `T` has type "reference to `T1`" then the member typedef `type` denotes `T1`; otherwise, `type` denotes `T`.
`template<class T>` `struct` `add_lvalue_reference;`	If `T` is a referenceable type (3.46) then the member typedef `type` denotes `T&`; otherwise, `type` denotes `T`. [*Note 1*: This rule reflects the semantics of reference collapsing (9.3.4.3). — *end note*]
`template<class T>` `struct` `add_rvalue_reference;`	If `T` is a referenceable type then the member typedef `type` denotes `T&&`; otherwise, `type` denotes `T`. [*Note 2*: This rule reflects the semantics of reference collapsing (9.3.4.3). For example, when a type `T` is a reference type `T1&`, the type `add_rvalue_reference_t<T>` is not an rvalue reference. — *end note*]

21.3.8.4 Sign modifications [meta.trans.sign]

1 The templates specified in Table 59 convert an integer type to its corresponding signed or unsigned type.

Table 59 — Sign modifications [tab:meta.trans.sign]

Template	Comments
`template<class T>` `struct make_signed;`	If `T` is a (possibly cv-qualified) signed integer type (6.9.2) then the member typedef `type` denotes `T`; otherwise, if `T` is a (possibly cv-qualified) unsigned integer type then `type` denotes the corresponding signed integer type, with the same cv-qualifiers as `T`; otherwise, `type` denotes the signed integer type with smallest rank (6.9.6) for which `sizeof(T) == sizeof(type)`, with the same cv-qualifiers as `T`. *Mandates*: `T` is an integral or enumeration type other than *cv* `bool`.
`template<class T>` `struct make_unsigned;`	If `T` is a (possibly cv-qualified) unsigned integer type (6.9.2) then the member typedef `type` denotes `T`; otherwise, if `T` is a (possibly cv-qualified) signed integer type then `type` denotes the corresponding unsigned integer type, with the same cv-qualifiers as `T`; otherwise, `type` denotes the unsigned integer type with smallest rank (6.9.6) for which `sizeof(T) == sizeof(type)`, with the same cv-qualifiers as `T`. *Mandates*: `T` is an integral or enumeration type other than *cv* `bool`.

21.3.8.5 Array modifications [meta.trans.arr]

1 The templates specified in Table 60 modify array types.

Table 60 — Array modifications [tab:meta.trans.arr]

Template	Comments
`template<class T>` `struct remove_extent;`	If `T` is a type "array of `U`", the member typedef `type` denotes `U`, otherwise `T`. [*Note 1*: For multidimensional arrays, only the first array dimension is removed. For a type "array of `const U`", the resulting type is `const U`. — *end note*]
`template<class T>` `struct remove_all_extents;`	If `T` is "multidimensional array of `U`", the resulting member typedef `type` denotes `U`, otherwise `T`.

2 [*Example 1*:

```
// the following assertions hold:
static_assert(is_same_v<remove_extent_t<int>, int>);
static_assert(is_same_v<remove_extent_t<int[2]>, int>);
static_assert(is_same_v<remove_extent_t<int[2][3]>, int[3]>);
static_assert(is_same_v<remove_extent_t<int[][3]>, int[3]>);
```

— *end example*]

3 [*Example 2*:

```
// the following assertions hold:
static_assert(is_same_v<remove_all_extents_t<int>, int>);
static_assert(is_same_v<remove_all_extents_t<int[2]>, int>);
static_assert(is_same_v<remove_all_extents_t<int[2][3]>, int>);
static_assert(is_same_v<remove_all_extents_t<int[][3]>, int>);
```

— *end example*]

21.3.8.6 Pointer modifications [meta.trans.ptr]

1 The templates specified in Table 61 add or remove pointers.

Table 61 — Pointer modifications [tab:meta.trans.ptr]

Template	Comments
`template<class T>` `struct remove_pointer;`	If `T` has type "(possibly cv-qualified) pointer to `T1`" then the member typedef `type` denotes `T1`; otherwise, it denotes `T`.
`template<class T>` `struct add_pointer;`	If `T` is a referenceable type (3.46) or a *cv* `void` type then the member typedef `type` denotes `remove_reference_t<T>*`; otherwise, `type` denotes `T`.

21.3.8.7 Other transformations [meta.trans.other]

1 The templates specified in Table 62 perform other modifications of a type.

Table 62 — Other transformations [tab:meta.trans.other]

Template	Comments
`template<class T>` `struct type_identity;`	The member typedef `type` denotes `T`.
`template<class T>` `struct remove_cvref;`	The member typedef `type` denotes `remove_cv_t<remove_reference_t<T>>`.

Table 62 — Other transformations (continued)

Template	Comments
`template<class T>` `struct decay;`	Let `U` be `remove_reference_t<T>`. If `is_array_v<U>` is `true`, the member typedef `type` denotes `remove_extent_t<U>*`. If `is_function_v<U>` is `true`, the member typedef `type` denotes `add_pointer_t<U>`. Otherwise the member typedef `type` denotes `remove_cv_t<U>`. [*Note 1*: This behavior is similar to the lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) conversions applied when an lvalue is used as an rvalue, but also strips cv-qualifiers from class types in order to more closely model by-value argument passing. — *end note*]
`template<bool B, class T =` `void> struct enable_if;`	If `B` is `true`, the member typedef `type` denotes `T`; otherwise, there shall be no member `type`.
`template<bool B, class T,` `class F>` `struct conditional;`	If `B` is `true`, the member typedef `type` denotes `T`. If `B` is `false`, the member typedef `type` denotes `F`.
`template<class... T> struct` `common_type;`	Unless this trait is specialized, the member `type` is declared or omitted as specified below. If it is omitted, there shall be no member `type`. Each type in the template parameter pack `T` shall be complete, *cv* `void`, or an array of unknown bound.
`template<class, class,` `  template<class> class,` `  template<class> class>` `struct` `  basic_common_reference;`	Unless this trait is specialized, there shall be no member `type`.
`template<class... T> struct` `common_reference;`	The member *typedef-name* `type` is declared or omitted as specified below. Each type in the parameter pack `T` shall be complete or *cv* `void`.
`template<class T>` `struct underlying_type;`	If `T` is an enumeration type, the member typedef `type` denotes the underlying type of `T` (9.8.1); otherwise, there is no member `type`. *Mandates*: `T` is not an incomplete enumeration type.
`template<class Fn,` `class... ArgTypes>` `struct invoke_result;`	If the expression *`INVOKE`*`(declval<Fn>(),` `declval<ArgTypes>()...)` (22.10.4) is well-formed when treated as an unevaluated operand (7.2.3), the member typedef `type` denotes the type `decltype(`*`INVOKE`*`(declval<Fn>(),` `declval<ArgTypes>()...))`; otherwise, there shall be no member `type`. Access checking is performed as if in a context unrelated to `Fn` and `ArgTypes`. Only the validity of the immediate context of the expression is considered. [*Note 2*: The compilation of the expression can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the "immediate context" and can result in the program being ill-formed. — *end note*] *Preconditions*: `Fn` and all types in the template parameter pack `ArgTypes` are complete types, *cv* `void`, or arrays of unknown bound.

Table 62 — Other transformations (continued)

Template	Comments
`template<class Fn, class Tuple> struct apply_result;`	If *tuple-like*`<Tuple>` is `true` and the expression *INVOKE*`(declval<Fn>(), `*ELEMS-OF*`(Tuple)...)` (22.10.4) is well-formed when treated as an unevaluated operand (7.2.3), the member typedef `type` denotes the type `decltype(`*INVOKE*`(declval<Fn>(), `*ELEMS-OF*`(Tuple)...))`; otherwise, there shall be no member `type`. Access checking is performed as if in a context unrelated to `Fn` and `Tuple`. Only the validity of the immediate context of the expression is considered. [*Note 3*: The compilation of the expression can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the "immediate context" and can result in the program being ill-formed. — *end note*] *Preconditions*: `Fn` and `Tuple` are complete types, *cv* `void`, or arrays of unknown bound.
`template<class T> struct unwrap_reference;`	If `T` is a specialization `reference_wrapper<X>` for some type `X`, the member typedef `type` of `unwrap_reference<T>` denotes `X&`, otherwise `type` denotes `T`.
`template<class T> unwrap_ref_decay;`	The member typedef `type` of `unwrap_ref_decay<T>` denotes the type `unwrap_reference_t<decay_t<T>>`.

2 In addition to being available via inclusion of the `<type_traits>` header, the templates `unwrap_reference`, `unwrap_ref_decay`, `unwrap_reference_t`, and `unwrap_ref_decay_t` are available when the header `<functional>` (22.10.2) is included.

3 Let:

(3.1) — *CREF*`(A)` be `add_lvalue_reference_t<const remove_reference_t<A>>`,

(3.2) — *XREF*`(A)` denote a unary alias template `T` such that `T<U>` denotes the same type as `U` with the addition of `A`'s cv and reference qualifiers, for a non-reference cv-unqualified type `U`,

(3.3) — *COPYCV*`(FROM, TO)` be an alias for type `TO` with the addition of `FROM`'s top-level cv-qualifiers,

[*Example 1*: *COPYCV*`(const int, volatile short)` is an alias for `const volatile short`. — *end example*]

(3.4) — *COND-RES*`(X, Y)` be `decltype(false ? declval<X(&)()>()() : declval<Y(&)()>()())`.

Given types `A` and `B`, let `X` be `remove_reference_t<A>`, let `Y` be `remove_reference_t<B>`, and let *COMMON-REF*`(A, B)` be:

(3.5) — If `A` and `B` are both lvalue reference types, *COMMON-REF*`(A, B)` is *COND-RES*`(`*COPYCV*`(X, Y) &, `*COPYCV*`(Y, X) &)` if that type exists and is a reference type.

(3.6) — Otherwise, let `C` be `remove_reference_t<`*COMMON-REF*`(X&, Y&)>&&`. If `A` and `B` are both rvalue reference types, `C` is well-formed, and `is_convertible_v<A, C> && is_convertible_v<B, C>` is `true`, then *COMMON-REF*`(A, B)` is `C`.

(3.7) — Otherwise, let `D` be *COMMON-REF*`(const X&, Y&)`. If `A` is an rvalue reference and `B` is an lvalue reference and `D` is well-formed and `is_convertible_v<A, D>` is `true`, then *COMMON-REF*`(A, B)` is `D`.

(3.8) — Otherwise, if `A` is an lvalue reference and `B` is an rvalue reference, then *COMMON-REF*`(A, B)` is *COMMON-REF*`(B, A)`.

(3.9) — Otherwise, *COMMON-REF*`(A, B)` is ill-formed.

If any of the types computed above is ill-formed, then *COMMON-REF*`(A, B)` is ill-formed.

4 For the `common_type` trait applied to a template parameter pack `T` of types, the member `type` shall be either declared or not present as follows:

(4.1) — If `sizeof...(T)` is zero, there shall be no member `type`.

(4.2) — If `sizeof...(T)` is one, let `T0` denote the sole type constituting the pack `T`. The member *typedef-name* `type` shall denote the same type, if any, as `common_type_t<T0, T0>`; otherwise there shall be no member `type`.

(4.3) — If `sizeof...(T)` is two, let the first and second types constituting `T` be denoted by `T1` and `T2`, respectively, and let `D1` and `D2` denote the same types as `decay_t<T1>` and `decay_t<T2>`, respectively.

(4.3.1) — If `is_same_v<T1, D1>` is `false` or `is_same_v<T2, D2>` is `false`, let `C` denote the same type, if any, as `common_type_t<D1, D2>`.

(4.3.2) — [*Note 4*: None of the following will apply if there is a specialization `common_type<D1, D2>`. — *end note*]

(4.3.3) — Otherwise, if

```
decay_t<decltype(false ? declval<D1>() : declval<D2>())>
```

denotes a valid type, let `C` denote that type.

(4.3.4) — Otherwise, if *COND-RES*(*CREF*(`D1`), *CREF*(`D2`)) denotes a type, let `C` denote the type `decay_t<`*COND-RES*(*CREF*(`D1`), *CREF*(`D2`))`>`.

In either case, the member *typedef-name* `type` shall denote the same type, if any, as `C`. Otherwise, there shall be no member `type`.

(4.4) — If `sizeof...(T)` is greater than two, let `T1`, `T2`, and `R`, respectively, denote the first, second, and (pack of) remaining types constituting `T`. Let `C` denote the same type, if any, as `common_type_t<T1, T2>`. If there is such a type `C`, the member *typedef-name* `type` shall denote the same type, if any, as `common_type_t<C, R...>`. Otherwise, there shall be no member `type`.

5 Notwithstanding the provisions of 21.3.2, and pursuant to 16.4.5.2.1, a program may specialize `common_type<T1, T2>` for types `T1` and `T2` such that `is_same_v<T1, decay_t<T1>>` and `is_same_v<T2, decay_t<T2>>` are each `true`.

[*Note 5*: Such specializations are needed when only explicit conversions are desired between the template arguments. — *end note*]

Such a specialization need not have a member named `type`, but if it does, the *qualified-id* `common_type<T1, T2>::type` shall denote a cv-unqualified non-reference type to which each of the types `T1` and `T2` is explicitly convertible. Moreover, `common_type_t<T1, T2>` shall denote the same type, if any, as does `common_type_t<T2, T1>`. No diagnostic is required for a violation of this Note's rules.

6 For the `common_reference` trait applied to a parameter pack `T` of types, the member `type` shall be either declared or not present as follows:

(6.1) — If `sizeof...(T)` is zero, there shall be no member `type`.

(6.2) — Otherwise, if `sizeof...(T)` is one, let `T0` denote the sole type in the pack `T`. The member typedef `type` shall denote the same type as `T0`.

(6.3) — Otherwise, if `sizeof...(T)` is two, let `T1` and `T2` denote the two types in the pack `T`. Then

(6.3.1) — Let `R` be *COMMON-REF*(`T1, T2`). If `T1` and `T2` are reference types, `R` is well-formed, and `is_convertible_v<add_pointer_t<T1>, add_pointer_t<R>> && is_convertible_v<add_pointer_t<T2>, add_pointer_t<R>>` is `true`, then the member typedef `type` denotes `R`.

(6.3.2) — Otherwise, if `basic_common_reference<remove_cvref_t<T1>, remove_cvref_t<T2>,` *XREF*`(T1),` *XREF*`(T2)>::type` is well-formed, then the member typedef `type` denotes that type.

(6.3.3) — Otherwise, if *COND-RES*(`T1, T2`) is well-formed, then the member typedef `type` denotes that type.

(6.3.4) — Otherwise, if `common_type_t<T1, T2>` is well-formed, then the member typedef `type` denotes that type.

(6.3.5) — Otherwise, there shall be no member `type`.

(6.4) — Otherwise, if `sizeof...(T)` is greater than two, let `T1`, `T2`, and `Rest`, respectively, denote the first, second, and (pack of) remaining types comprising `T`. Let `C` be the type `common_reference_t<T1, T2>`. Then:

(6.4.1) — If there is such a type `C`, the member typedef `type` shall denote the same type, if any, as `common_reference_t<C, Rest...>`.

(6.4.2) — Otherwise, there shall be no member `type`.

7 Notwithstanding the provisions of 21.3.2, and pursuant to 16.4.5.2.1, a program may partially specialize `basic_common_reference<T, U, TQual, UQual>` for types `T` and `U` such that `is_same_v<T, decay_t<T>>` and `is_same_v<U, decay_t<U>>` are each `true`.

[*Note 6*: Such specializations can be used to influence the result of `common_reference`, and are needed when only explicit conversions are desired between the template arguments. — *end note*]

Such a specialization need not have a member named `type`, but if it does, the *qualified-id* `basic_common_reference<T, U, TQual, UQual>::type` shall denote a type to which each of the types `TQual<T>` and `UQual<U>` is convertible. Moreover, `basic_common_reference<T, U, TQual, UQual>::type` shall denote the same type, if any, as does `basic_common_reference<U, T, UQual, TQual>::type`. No diagnostic is required for a violation of these rules.

8 [*Example 2*: Given these declarations:

```
using PF1 = bool  (&)();
using PF2 = short (*)(long);

struct S {
  operator PF2() const;
  double operator()(char, int&);
  void fn(long) const;
  char data;
};

using PMF = void (S::*)(long) const;
using PMD = char  S::*;
```

the following assertions will hold:

```
static_assert(is_same_v<invoke_result_t<S, int>, short>);
static_assert(is_same_v<invoke_result_t<S&, unsigned char, int&>, double>);
static_assert(is_same_v<invoke_result_t<PF1>, bool>);
static_assert(is_same_v<invoke_result_t<PMF, unique_ptr<S>, int>, void>);
static_assert(is_same_v<invoke_result_t<PMD, S>, char&&>);
static_assert(is_same_v<invoke_result_t<PMD, const S*>, const char&>);
```

— *end example*]

21.3.9 Logical operator traits [meta.logical]

1 This subclause describes type traits for applying logical operators to other type traits.

```
template<class... B> struct conjunction : see below { };
```

2 The class template `conjunction` forms the logical conjunction of its template type arguments.

3 For a specialization `conjunction<`B_1`, ..., `B_N`>`, if there is a template type argument B_i for which `bool(`B_i`::value)` is `false`, then instantiating `conjunction<`B_1`, ..., `B_N`>::value` does not require the instantiation of B_j`::value` for $j > i$.

[*Note 1*: This is analogous to the short-circuiting behavior of the built-in operator `&&`. — *end note*]

4 Every template type argument for which B_i`::value` is instantiated shall be usable as a base class and shall have a member `value` which is convertible to `bool`, is not hidden, and is unambiguously available in the type.

5 The specialization `conjunction<`B_1`, ..., `B_N`>` has a public and unambiguous base that is either

(5.1) — the first type B_i in the list `true_type, `B_1`, ..., `B_N for which `bool(`B_i`::value)` is `false`, or

(5.2) — if there is no such B_i, the last type in the list.

[*Note 2*: This means a specialization of `conjunction` does not necessarily inherit from either `true_type` or `false_type`. — *end note*]

6 The member names of the base class, other than `conjunction` and `operator=`, shall not be hidden and shall be unambiguously available in `conjunction`.

```
template<class... B> struct disjunction : see below { };
```

7 The class template `disjunction` forms the logical disjunction of its template type arguments.

8 For a specialization `disjunction<`B_1`, ..., `B_N`>`, if there is a template type argument B_i for which `bool(`B_i`::value)` is `true`, then instantiating `disjunction<`B_1`, ..., `B_N`>::value` does not require the instantiation of B_j`::value` for $j > i$.

[*Note 3*: This is analogous to the short-circuiting behavior of the built-in operator `||`. — *end note*]

9 Every template type argument for which `B`$_i$`::value` is instantiated shall be usable as a base class and shall have a member `value` which is convertible to `bool`, is not hidden, and is unambiguously available in the type.

10 The specialization `disjunction<B`$_1$`, ..., B`$_N$`>` has a public and unambiguous base that is either

(10.1) — the first type `B`$_i$ in the list `false_type, B`$_1$`, ..., B`$_N$ for which `bool(B`$_i$`::value)` is `true`, or

(10.2) — if there is no such `B`$_i$, the last type in the list.

[*Note 4*: This means a specialization of `disjunction` does not necessarily inherit from either `true_type` or `false_type`. — *end note*]

11 The member names of the base class, other than `disjunction` and `operator=`, shall not be hidden and shall be unambiguously available in `disjunction`.

```
template<class B> struct negation : see below { };
```

12 The class template `negation` forms the logical negation of its template type argument. The type `negation<B>` is a *Cpp17UnaryTypeTrait* with a base characteristic of `bool_constant<!bool(B::value)>`.

21.3.10 Member relationships [meta.member]

```
template<class S, class M>
  constexpr bool is_pointer_interconvertible_with_class(M S::*m) noexcept;
```

1 *Mandates*: `S` is a complete type.

2 *Returns*: `true` if and only if `S` is a standard-layout type, `M` is an object type, `m` is not null, and each object `s` of type `S` is pointer-interconvertible (6.9.4) with its subobject `s.*m`.

```
template<class S1, class S2, class M1, class M2>
  constexpr bool is_corresponding_member(M1 S1::*m1, M2 S2::*m2) noexcept;
```

3 *Mandates*: `S1` and `S2` are complete types.

4 *Returns*: `true` if and only if `S1` and `S2` are standard-layout struct (11.2) types, `M1` and `M2` are object types, `m1` and `m2` are not null, and `m1` and `m2` point to corresponding members of the common initial sequence (11.4) of `S1` and `S2`.

5 [*Note 1*: The type of a pointer-to-member expression `&C::b` is not always a pointer to member of `C`, leading to potentially surprising results when using these functions in conjunction with inheritance.

[*Example 1*:

```
struct A { int a; };                    // a standard-layout class
struct B { int b; };                    // a standard-layout class
struct C: public A, public B { };       // not a standard-layout class

static_assert( is_pointer_interconvertible_with_class( &C::b ) );
  // Succeeds because, despite its appearance, &C::b has type
  // "pointer to member of B of type int".
static_assert( !is_pointer_interconvertible_with_class<C, int>( &C::b ) );
  // Forces the use of class C, and the result is false.

static_assert( is_corresponding_member( &C::a, &C::b ) );
  // Succeeds because, despite its appearance, &C::a and &C::b have types
  // "pointer to member of A of type int" and
  // "pointer to member of B of type int", respectively.
static_assert( !is_corresponding_member<C, C, int, int>( &C::a, &C::b ) );
  // Forces the use of class C, and the result is false.
```

— *end example*]

— *end note*]

21.3.11 Constant evaluation context [meta.const.eval]

```
constexpr bool is_constant_evaluated() noexcept;
```

1 *Effects*: Equivalent to:

```
if consteval {
  return true;
} else {
  return false;
}
```

2 [*Example 1*:

```
constexpr void f(unsigned char *p, int n) {
  if (std::is_constant_evaluated()) {          // should not be a constexpr if statement
    for (int k = 0; k<n; ++k) p[k] = 0;
  } else {
    memset(p, 0, n);                           // not a core constant expression
  }
}
```

— *end example*]

```
template<class U = void, class T>
  consteval bool is_within_lifetime(const T* p) noexcept;
```

3 *Mandates*: `static_cast<const volatile U*>(p)` is well-formed.

4 *Returns*: `true` if `p` is a pointer to an object that is within its lifetime (6.8.4) and `static_cast<const volatile U*>(p)` is a constant subexpression; otherwise, `false`.

5 *Remarks*: During the evaluation of an expression `E` as a core constant expression, a call to this function is ill-formed unless `p` points to an object that is usable in constant expressions or whose complete object's lifetime began within `E`.

6 [*Example 2*:

```
struct OptBool {
  union { bool b; char c; };

  // note: this assumes common implementation properties for bool and char:
  // * sizeof(bool) == sizeof(char), and
  // * the value representations for true and false are distinct
  // from the value representation for 2
  constexpr OptBool() : c(2) { }
  constexpr OptBool(bool b) : b(b) { }

  constexpr auto has_value() const -> bool {
    if consteval {
      return std::is_within_lifetime(&b);      // during constant evaluation, cannot read from c
    } else {
      return c != 2;                           // during runtime, must read from c
    }
  }

  constexpr auto operator*() const -> const bool& {
    return b;
  }
};

constexpr OptBool disengaged;
constexpr OptBool engaged(true);
static_assert(!disengaged.has_value());
static_assert(engaged.has_value());
static_assert(*engaged);
```

— *end example*]

21.4 Reflection [meta.reflection]

21.4.1 Header <meta> synopsis [meta.syn]

```

  consteval info apply_result(info fn, info tuple);

  consteval size_t variant_size(info type);
  consteval info variant_alternative(size_t index, info type);

  consteval strong_ordering type_order(info type_a, info type_b);
}
```

1 Unless otherwise specified, each function, and each specialization of any function template, specified in this header is a designated addressable function (16.4.5.2.1).

2 When a function or function template specialization F specified in this header throws a `meta::exception` E, E`.from()` is a reflection representing F and E`.where()` is a `source_location` representing from where the call to F originated.

3 The behavior of any function specified in namespace `std::meta` is implementation-defined when a reflection of a construct not otherwise specified by this document is provided as an argument.

[*Note 1*: Values of type `std::meta::info` can represent implementation-specific constructs (6.9.2). — *end note*]

[*Note 2*: Many of the functions specified in namespace `std::meta` have semantics that can be affected by the completeness of class types represented by reflection values. For such functions, for any reflection `r` such that `dealias(r)` represents a specialization of a templated class with a reachable definition, the specialization is implicitly instantiated (13.9.2).

[*Example 1*:

```
template<class T>
struct X {
  T mem;
};

static_assert(size_of(^^X<int>) == sizeof(int));     // instantiates X<int>
```

— *end example*]

— *end note*]

4 Any function in namespace `std::meta` whose return type is `string_view` or `u8string_view` returns an object `V` such that `V.data()[V.size()]` equals `'\0'`. Each element of the range `V.data()` + [0, `V.size()`] is a potentially non-unique object with static storage duration that is usable in constant expressions (6.8.2, 7.7); a pointer to such an element is not suitable for use as a template argument for a constant template parameter of pointer type (13.4.3).

[*Example 2*:

```
struct C { };

constexpr string_view sv = identifier_of(^^C);
static_assert(sv == "C");
static_assert(sv.data()[0] == 'C');
static_assert(sv.data()[1] == '\0');
```

— *end example*]

5 For the purpose of exposition, throughout this clause `^^`*`E`* is used to indicate a reflection representing source construct *`E`*.

21.4.2 Checking string literals [meta.string.literal]

```
consteval bool is_string_literal(const char* p);
consteval bool is_string_literal(const wchar_t* p);
consteval bool is_string_literal(const char8_t* p);
consteval bool is_string_literal(const char16_t* p);
consteval bool is_string_literal(const char32_t* p);
```

1 *Returns*:

(1.1) — If `p` points to an unspecified object (7.7.2), `false`.

(1.2) — Otherwise, if `p` points to a subobject of a string literal object (5.13.5), `true`.

(1.3) — Otherwise, `false`.

21.4.3 Promoting to static storage [meta.define.static]

1 The functions in this subclause promote compile-time storage into static storage.

```
template<ranges::input_range R>
  consteval info reflect_constant_string(R&& r);
```

2 Let `CharT` be `ranges::range_value_t<R>`.

3 *Mandates*: `CharT` is a character type (6.9.2).

4 Let V be the pack of values of type `CharT` whose elements are the corresponding elements of `r`, except that if `r` is a reference to a string literal object, then V does not include the terminating U+0000 NULL character of `r`.

5 Let P be the template parameter object (13.2) of type `const CharT[sizeof...(V) + 1]` initialized with `{`V`..., CharT()}`.

6 *Returns*: `^^`P.

7 [*Note 1*: P is a potentially non-unique object (6.8.2). — *end note*]

```
template<ranges::input_range R>
  consteval info reflect_constant_array(R&& r);
```

8 Let `U` be `ranges::range_value_t<R>` and `T` be `remove_all_extents_t<U>`.

9 *Mandates*:

(9.1) — `T` is a structural type (13.2),

(9.2) — `T` satisfies `copy_constructible`, and

(9.3) — if `U` is not an array type, then `is_constructible_v<T, ranges::range_reference_t<R>>` is `true`.

10 Let V be the pack of values of type `info` of the same size as `r`, where the i^{th} element is

(10.1) — `reflect_constant_array(*`it_i`)` if `U` is an array type,

(10.2) — `reflect_constant(static_cast<T>(*`it_i`))` otherwise,

and it_i is an iterator to the i^{th} element of `r`.

11 Let P be

(11.1) — the template parameter object (13.2) of type `const T[sizeof...(`V`)]`, such that P`[`I`]` is template-argument-equivalent (13.6) to the object represented by V`...[`I`]` for all I in the range [`0`, `sizeof...(`V`)`) if `sizeof...(`V`) > 0` is `true`, otherwise

(11.2) — the template parameter object of type `const array<T, 0>` initialized with `{}`.

12 *Returns*: `^^`P.

13 *Throws*: Any of

(13.1) — an exception thrown by any operation on `r` or on iterators and sentinels referring to `r`,

(13.2) — an exception thrown by the evaluation of any argument of `reflect_constant` or by any evaluation of `reflect_constant_array`, or

(13.3) — `meta::exception` if any invocation of `reflect_constant` would exit via an exception.

14 [*Note 2*: When `r` is not empty, P is a potentially non-unique object (6.8.2). — *end note*]

```
template<ranges::input_range R>
  consteval const ranges::range_value_t<R>* define_static_string(R&& r);
```

15 *Effects*: Equivalent to:

```
return meta::extract<const ranges::range_value_t<R>*>(meta::reflect_constant_string(r));
```

```
template<ranges::input_range R>
  consteval span<const ranges::range_value_t<R>, see below> define_static_array(R&& r);
```

16 *Effects*: Equivalent to:

```
using T = ranges::range_value_t<R>;
meta::info array = meta::reflect_constant_array(r);
if (meta::is_array_type(meta::type_of(array))) {
  return span<const T, see below>(meta::extract<const T*>(array),
                                  meta::extent(meta::type_of(array)));
} else {
  return span<const T, see below>(static_cast<const T*>(nullptr), 0);
}
```

17 *Remarks*: If `ranges::size(r)` is a constant expression, the second template argument of the returned `span` type is `static_cast<size_t>(ranges::size(r))`; otherwise, it is `dynamic_extent`.

```
template<class T>
  consteval const remove_cvref_t<T>* define_static_object(T&& t);
```

18 *Effects*: Equivalent to:

```
using U = remove_cvref_t<T>;
if constexpr (meta::is_class_type(^^U) || meta::is_union_type(^^U)) {
  return addressof(meta::extract<const U&>(
                     meta::reflect_constant(std::forward<T>(t))));
} else if constexpr (meta::is_array_type(^^U)) {
  return addressof(meta::extract<const U&>(
                     meta::reflect_constant_array(std::forward<T>(t))));
} else {
  return define_static_array(span(addressof(t), 1)).data();
}
```

19 [*Note 3*: For class types, `define_static_object` provides the address of the template parameter object (13.2) that is template-argument equivalent to `t`. — *end note*]

21.4.4 Class `exception` [meta.reflection.exception]

```
namespace std::meta {
  class exception : public std::exception {
  private:
    optional<string> what_;      // exposition only
    u8string u8what_;            // exposition only
    info from_;                  // exposition only
    source_location where_;      // exposition only

  public:
    consteval exception(u8string_view what, info from,
                        source_location where = source_location::current()) noexcept;

    consteval exception(string_view what, info from,
                        source_location where = source_location::current()) noexcept;

    exception(const exception&) = default;
    exception(exception&&) = default;

    exception& operator=(const exception&) = default;
    exception& operator=(exception&&) = default;

    constexpr const char* what() const noexcept override;
    consteval u8string_view u8what() const noexcept;
    consteval info from() const noexcept;
    consteval source_location where() const noexcept;
  };
}
```

1 Reflection functions throw exceptions of type `meta::exception` to signal an error. `meta::exception` is a consteval-only type.

```
consteval exception(u8string_view what, info from,
                    source_location where = source_location::current()) noexcept;
```

2 *Effects*: Initializes *`u8what_`* with `what`, *`from_`* with `from`, and *`where_`* with `where`. If `what` can be represented in the ordinary literal encoding, initializes *`what_`* with `what`, transcoded from UTF-8 to the ordinary literal encoding. Otherwise, *`what_`* is value-initialized.

```
consteval exception(string_view what, info from,
                    source_location where = source_location::current()) noexcept;
```

3 *Constant When*: `what` designates a sequence of characters that can be encoded in UTF-8.

4 *Effects*: Initializes *`what_`* with `what`, *`u8what_`* with `what` transcoded from the ordinary literal encoding to UTF-8, *`from_`* with `from` and *`where_`* with `where`.

```
constexpr const char* what() const noexcept override;
```

5 *Constant When*: *what_*.has_value() is true.

6 *Returns*: *what_*->c_str().

```
consteval u8string_view u8what() const noexcept;
```

7 *Returns*: *u8what_*.

```
consteval info from() const noexcept;
```

8 *Returns*: *from_*.

```
consteval source_location where() const noexcept;
```

9 *Returns*: *where_*.

21.4.5 Operator representations [meta.reflection.operators]

```
enum class operators {
  see below;
};
using enum operators;
```

1 The enumeration type `operators` specifies constants used to identify operators that can be overloaded, with the meanings listed in Table 63. The values of the constants are distinct.

```
consteval operators operator_of(info r);
```

2 *Returns*: The value of the enumerator from `operators` whose corresponding *operator-function-id* is the unqualified name of the entity represented by `r`.

3 *Throws*: `meta::exception` unless `r` represents an operator function or operator function template.

```
consteval string_view symbol_of(operators op);
consteval u8string_view u8symbol_of(operators op);
```

4 *Returns*: A `string_view` or `u8string_view` containing the characters of the operator symbol name corresponding to `op`, respectively encoded with the ordinary literal encoding or with UTF-8.

5 *Throws*: `meta::exception` unless the value of `op` corresponds to one of the enumerators in `operators`.

21.4.6 Reflection names and locations [meta.reflection.names]

```
consteval bool has_identifier(info r);
```

1 *Returns*:

(1.1) — If `r` represents an entity that has a typedef name for linkage purposes (9.2.4), then `true`.

(1.2) — Otherwise, if `r` represents an unnamed entity, then `false`.

(1.3) — Otherwise, if `r` represents a type alias, then `!has_template_arguments(r)`.

(1.4) — Otherwise, if `r` represents a type, then `true` if

(1.4.1) — `r` represents a cv-unqualified class type and `has_template_arguments(r)` is `false`, or

(1.4.2) — `r` represents a cv-unqualified enumeration type.

Otherwise, `false`.

(1.5) — Otherwise, if `r` represents a function, then `true` if `has_template_arguments(r)` is `false` and the function is not a constructor, destructor, operator function, or conversion function. Otherwise, `false`.

(1.6) — Otherwise, if `r` represents a template, then `true` if `r` does not represent a constructor template, operator function template, or conversion function template. Otherwise, `false`.

(1.7) — Otherwise, if `r` represents the i^{th} parameter of a function F that is an (implicit or explicit) specialization of a templated function T and the i^{th} parameter of the instantiated declaration of T whose template arguments are those of F would be instantiated from a pack, then `false`.

Table 63 — Enum class `operators` [tab:meta.reflection.operators]

Constant	Corresponding *operator-function-id*	Operator symbol name

©ISO/IEC

(1.8) — Otherwise, if `r` represents the parameter P of a function F, then let S be the set of declarations, ignoring any explicit instantiations, that are reachable from a point in the evaluation context and that declare either F or a templated function of which F is a specialization; `true` if

(1.8.1) — there is a declaration D in S that introduces a name N for either P or the parameter corresponding to P in the templated function that D declares and

(1.8.2) — no declaration in S does so using any name other than N.

Otherwise, `false`.

[*Example 1*:

```
void fun(int);
constexpr std::meta::info r = parameters_of(^^fun)[0];
static_assert(!has_identifier(r));

void fun(int x);
static_assert(has_identifier(r));

void fun(int x);
static_assert(has_identifier(r));

void poison() {
  void fun(int y);
}
static_assert(!has_identifier(r));
```

— *end example*]

(1.9) — Otherwise, if `r` represents a variable, then `false` if the declaration of that variable was instantiated from a function parameter pack. Otherwise, `!has_template_arguments(r)`.

(1.10) — Otherwise, if `r` represents a structured binding, then `false` if the declaration of that structured binding was instantiated from a structured binding pack. Otherwise, `true`.

(1.11) — Otherwise, if `r` represents an enumerator, non-static-data member, namespace, or namespace alias, then `true`.

(1.12) — Otherwise, if `r` represents a direct base class relationship, then `has_identifier(type_of(r))`.

(1.13) — Otherwise, if `r` represents a data member description (T, N, A, W, NUA, ANN) (11.4.1); `true` if N is not $\perp$. Otherwise, `false`.

(1.14) — Otherwise, `false`.

```
consteval string_view identifier_of(info r);
consteval u8string_view u8identifier_of(info r);
```

2 Let E be UTF-8 for `u8identifier_of`, and otherwise the ordinary literal encoding.

3 *Returns*: An NTMBS, encoded with E, determined as follows:

(3.1) — If `r` represents an entity with a typedef name for linkage purposes, then that name.

(3.2) — Otherwise, if `r` represents a literal operator or literal operator template, then the *ud-suffix* of the operator or operator template.

(3.3) — Otherwise, if `r` represents the parameter P of a function F, then let S be the set of declarations, ignoring any explicit instantiations, that are reachable from a point in the evaluation context and that declare either F or a templated function of which F is a specialization; the name that was introduced by a declaration in S for the parameter corresponding to P.

(3.4) — Otherwise, if `r` represents an entity, then the identifier introduced by the declaration of that entity.

(3.5) — Otherwise, if `r` represents a direct base class relationship, then `identifier_of(type_of(r))` or `u8identifier_of(type_of(r))`, respectively.

(3.6) — Otherwise, `r` represents a data member description (T, N, A, W, NUA, ANN) (11.4.1); a `string_view` or `u8string_view`, respectively, containing the identifier N.

4 *Throws*: `meta::exception` unless `has_identifier(r)` is `true` and the identifier that would be returned (see above) is representable by E.

```
consteval string_view display_string_of(info r);
consteval u8string_view u8display_string_of(info r);
```

5 *Returns*: An implementation-defined `string_view` or `u8string_view`, respectively.

6 *Recommended practice*: Where possible, implementations should return a string suitable for identifying the represented construct.

```
consteval source_location source_location_of(info r);
```

7 *Returns*: If `r` represents a value, a type other than a class type or an enumeration type, the global namespace, or a data member description, then `source_location{}`. Otherwise, an implementation-defined `source_location` value.

8 *Recommended practice*: If `r` represents an entity with a definition that is reachable from the evaluation context, a value corresponding to a definition should be returned.

21.4.7 Reflection queries [meta.reflection.queries]

```
consteval bool has-type(info r);  // exposition only
```

1 *Returns*: `true` if `r` represents a value, annotation, object, variable, function whose type does not contain an undeduced placeholder type and that is not a constructor or destructor, enumerator, non-static data member, unnamed bit-field, direct base class relationship, data member description, or function parameter. Otherwise, `false`.

```
consteval info type_of(info r);
```

2 *Returns*:

(2.1) — If `r` represents the i^{th} parameter of a function F, then the i^{th} type in the parameter-type-list of F (9.3.4.6).

(2.2) — Otherwise, if `r` represents a value, object, variable, function, non-static data member, or unnamed bit-field, then the type of what is represented by `r`.

(2.3) — Otherwise, if `r` represents an annotation, then `type_of(constant_of(r))`.

(2.4) — Otherwise, if `r` represents an enumerator N of an enumeration E, then:

(2.4.1) — If E is defined by a declaration D that is reachable from a point P in the evaluation context and P does not occur within an *enum-specifier* of D, then a reflection of E.

(2.4.2) — Otherwise, a reflection of the type of N prior to the closing brace of the *enum-specifier* as specified in 9.8.1.

(2.5) — Otherwise, if `r` represents a direct base class relationship (D, B), then a reflection of B.

(2.6) — Otherwise, for a data member description (T, N, A, W, NUA, ANN) (11.4.1), a reflection of the type T.

3 *Throws*: `meta::exception` unless `has-type(r)` is `true`.

```
consteval info object_of(info r);
```

4 *Returns*:

(4.1) — If `r` represents an object, then `r`.

(4.2) — Otherwise, if `r` represents a reference, then a reflection of the object referred to by that reference.

(4.3) — Otherwise, `r` represents a variable; a reflection of the object declared by that variable.

5 *Throws*: `meta::exception` unless `r` is a reflection representing either

(5.1) — an object with static storage duration (6.8.6.1), or

(5.2) — a variable that either declares or refers to such an object, and if that variable is a reference R, then either

(5.2.1) — R is usable in constant expressions (7.7.4), or

(5.2.2) — the lifetime of R began within the core constant expression currently under evaluation.

6 [*Example 1*:

```
int x;
```

```
int& y = x;

static_assert(^^x != ^^y);                          // OK, r and y are different variables, so their
                                                    // reflections compare different
static_assert(object_of(^^x) == object_of(^^y));    // OK, because y is a reference
                                                    // to x, their underlying objects are the same
```

— *end example*]

```
consteval info constant_of(info r);
```

7 Let R be a constant expression of type `info` such that R `==` `r` is `true`. If `r` represents an annotation, then let C be its underlying constant.

8 *Effects*: Equivalent to:

```
if constexpr (is_annotation(R)) {
  return C;
} else if constexpr (is_array_type(type_of(R))) {
  return reflect_constant_array([: R :]);
} else if constexpr (is_function_type(type_of(R))) {
  return reflect_function([: R :]);
} else {
  return reflect_constant([: R :]);
}
```

9 *Throws*: `meta::exception` unless either `r` represents an annotation or `[: R :]` is a valid *splice-expression* (7.5.9).

10 [*Example 2*:

```
constexpr int x = 0;
constexpr int y = 0;

static_assert(^^x != ^^y);                          // OK, x and y are different variables,
                                                    // so their reflections compare different

static_assert(constant_of(^^x) ==                   // OK, both constant_of(^^x) and
              constant_of(^^y));                    // constant_of(^^y) represent the value 0

static_assert(constant_of(^^x) ==                   // OK, likewise
              reflect_constant(0));

struct S { int m; };
constexpr S s {42};

static_assert(is_object(constant_of(^^s)) &&
              is_object(reflect_object(s)));

static_assert(constant_of(^^s) !=                   // OK, template parameter object that is
              reflect_object(s));                   // template-argument-equivalent to s
                                                    // is a different object than s

static_assert(constant_of(^^s) ==
              constant_of(reflect_object(s)));

consteval info fn() {
  constexpr int x = 42;
  return ^^x;
}
constexpr info r = constant_of(fn());              // error: x is outside its lifetime
```

— *end example*]

```
consteval bool is_public(info r);
consteval bool is_protected(info r);
consteval bool is_private(info r);
```

11 *Returns*: `true` if `r` represents either

(11.1) — a class member or unnamed bit-field that is public, protected, or private, respectively, or

(11.2) — a direct base class relationship (D, B) for which B is, respectively, a public, protected, or private base class of D.

Otherwise, `false`.

```
consteval bool is_virtual(info r);
```

12 *Returns*: `true` if `r` represents either a virtual member function or a direct base class relationship (D, B) for which B is a virtual base class of D. Otherwise, `false`.

```
consteval bool is_pure_virtual(info r);
consteval bool is_override(info r);
```

13 *Returns*: `true` if `r` represents a member function that is pure virtual or overrides another member function, respectively. Otherwise, `false`.

```
consteval bool is_final(info r);
```

14 *Returns*: `true` if `r` represents a final class or a final member function. Otherwise, `false`.

```
consteval bool is_deleted(info r);
consteval bool is_defaulted(info r);
```

15 *Returns*: `true` if `r` represents a function that is a deleted function (9.6.3) or defaulted function (9.6.2), respectively. Otherwise, `false`.

```
consteval bool is_user_provided(info r);
consteval bool is_user_declared(info r);
```

16 *Returns*: `true` if `r` represents a function that is user-provided or user-declared (9.6.2), respectively. Otherwise, `false`.

```
consteval bool is_explicit(info r);
```

17 *Returns*: `true` if `r` represents a member function that is declared explicit. Otherwise, `false`.

[*Note 1*: If `r` represents a member function template that is declared explicit, `is_explicit(r)` is still `false` because in general, such queries for templates cannot be answered. — *end note*]

```
consteval bool is_noexcept(info r);
```

18 *Returns*: `true` if `r` represents a `noexcept` function type or a function with a non-throwing exception specification (14.5). Otherwise, `false`.

[*Note 2*: If `r` represents a function template that is declared `noexcept`, `is_noexcept(r)` is still `false` because in general, such queries for templates cannot be answered. — *end note*]

```
consteval bool is_bit_field(info r);
```

19 *Returns*: `true` if `r` represents a bit-field, or if `r` represents a data member description (T, N, A, W, NUA, ANN) (11.4.1) for which W is not $\bot$. Otherwise, `false`.

```
consteval bool is_enumerator(info r);
consteval bool is_annotation(info r);
```

20 *Returns*: `true` if `r` represents an enumerator or annotation, respectively. Otherwise, `false`.

```
consteval bool is_const(info r);
consteval bool is_volatile(info r);
```

21 Let T be `type_of(r)` if *`has-type`*`(r)` is `true`. Otherwise, let T be `dealias(r)`.

22 *Returns*: `true` if T represents a const or volatile type, respectively, or a const- or volatile-qualified function type, respectively. Otherwise, `false`.

```
consteval bool is_mutable_member(info r);
```

23 *Returns*: `true` if `r` represents a `mutable` non-static data member. Otherwise, `false`.

```
consteval bool is_lvalue_reference_qualified(info r);
consteval bool is_rvalue_reference_qualified(info r);
```

24 Let T be `type_of(r)` if *`has-type`*`(r)` is `true`. Otherwise, let T be `dealias(r)`.

25 *Returns*: `true` if T represents an lvalue- or rvalue-qualified function type, respectively. Otherwise, `false`.

```
consteval bool has_static_storage_duration(info r);
consteval bool has_thread_storage_duration(info r);
consteval bool has_automatic_storage_duration(info r);
```

26 *Returns*: `true` if `r` represents an object or variable that has static, thread, or automatic storage duration, respectively (6.8.6). Otherwise, `false`.

[*Note 3*: It is not possible to have a reflection representing an object or variable having dynamic storage duration. — *end note*]

```
consteval bool has_internal_linkage(info r);
consteval bool has_module_linkage(info r);
consteval bool has_external_linkage(info r);
consteval bool has_linkage(info r);
```

27 *Returns*: `true` if `r` represents a variable, function, type, template, or namespace whose name has internal linkage, module linkage, external linkage, or any linkage, respectively (6.7). Otherwise, `false`.

```
consteval bool has_c_language_linkage(info r);
```

28 *Returns*: `true` if `r` represents a variable, function, or function type with C language linkage. Otherwise, `false`.

```
consteval bool is_complete_type(info r);
```

29 *Returns*: `true` if `is_type(r)` is `true` and there is some point in the evaluation context from which the type represented by `dealias(r)` is not an incomplete type (6.9). Otherwise, `false`.

```
consteval bool is_enumerable_type(info r);
```

30 A type T is *enumerable* from a point P if either

(30.1) — T is a class type complete at point P or

(30.2) — T is an enumeration type defined by a declaration D such that D is reachable from P but P does not occur within an *enum-specifier* of D (9.8.1).

31 *Returns*: `true` if `dealias(r)` represents a type that is enumerable from some point in the evaluation context. Otherwise, `false`.

32 [*Example 3*:

```
class S;
enum class E;
static_assert(!is_enumerable_type(^^S));
static_assert(!is_enumerable_type(^^E));

class S {
  void mfn() {
    static_assert(is_enumerable_type(^^S));
  }
  static_assert(!is_enumerable_type(^^S));
};
static_assert(is_enumerable_type(^^S));

enum class E {
  A = is_enumerable_type(^^E) ? 1 : 2
};
static_assert(is_enumerable_type(^^E));
static_assert(static_cast<int>(E::A) == 2);
```

— *end example*]

```
consteval bool is_variable(info r);
```

33 *Returns*: `true` if `r` represents a variable. Otherwise, `false`.

```
consteval bool is_type(info r);
```

```
consteval bool is_namespace(info r);
```

34 *Returns*: `true` if `r` represents an entity whose underlying entity is a type or namespace, respectively. Otherwise, `false`.

```
consteval bool is_type_alias(info r);
consteval bool is_namespace_alias(info r);
```

35 *Returns*: `true` if `r` represents a type alias or namespace alias, respectively. Otherwise, `false`.

[*Note 4*: A specialization of an alias template is a type alias. — *end note*]

```
consteval bool is_function(info r);
```

36 *Returns*: `true` if `r` represents a function. Otherwise, `false`.

```
consteval bool is_conversion_function(info r);
consteval bool is_operator_function(info r);
consteval bool is_literal_operator(info r);
```

37 *Returns*: `true` if `r` represents a function that is a conversion function (11.4.8.3), operator function (12.4), or literal operator (12.6), respectively. Otherwise, `false`.

```
consteval bool is_special_member_function(info r);
consteval bool is_constructor(info r);
consteval bool is_default_constructor(info r);
consteval bool is_copy_constructor(info r);
consteval bool is_move_constructor(info r);
consteval bool is_assignment(info r);
consteval bool is_copy_assignment(info r);
consteval bool is_move_assignment(info r);
consteval bool is_destructor(info r);
```

38 *Returns*: `true` if `r` represents a function that is a special member function (11.4.4), a constructor, a default constructor, a copy constructor, a move constructor, an assignment operator, a copy assignment operator, a move assignment operator, or a destructor, respectively. Otherwise, `false`.

```
consteval bool is_function_parameter(info r);
```

39 *Returns*: `true` if `r` represents a function parameter. Otherwise, `false`.

```
consteval bool is_explicit_object_parameter(info r);
```

40 *Returns*: `true` if `r` represents a function parameter that is an explicit object parameter (9.3.4.6). Otherwise, `false`.

```
consteval bool has_default_argument(info r);
```

41 *Returns*: If `r` represents a parameter P of a function F, then:

(41.1) — If F is a specialization of a templated function T, then `true` if there exists a declaration D of T that is reachable from a point in the evaluation context and D specifies a default argument for the parameter of T corresponding to P. Otherwise, `false`.

(41.2) — Otherwise, if there exists a declaration D of F that is reachable from a point in the evaluation context and D specifies a default argument for P, then `true`.

Otherwise, `false`.

```
consteval bool is_vararg_function(info r);
```

42 *Returns*: `true` if `r` represents a function or function type that is a vararg function (9.3.4.6). Otherwise, `false`.

```
consteval bool is_template(info r);
```

43 *Returns*: `true` if `r` represents a function template, class template, variable template, alias template, or concept. Otherwise, `false`.

44 [*Note 5*: A template specialization is not a template. For example, `is_template(^^std::vector)` is `true` but `is_template(^^std::vector<int>)` is `false`. — *end note*]

```
consteval bool is_function_template(info r);
consteval bool is_variable_template(info r);
consteval bool is_class_template(info r);
consteval bool is_alias_template(info r);
consteval bool is_conversion_function_template(info r);
consteval bool is_operator_function_template(info r);
consteval bool is_literal_operator_template(info r);
consteval bool is_constructor_template(info r);
consteval bool is_concept(info r);
```

45 *Returns*: `true` if `r` represents a function template, variable template, class template, alias template, conversion function template, operator function template, literal operator template, constructor template, or concept, respectively. Otherwise, `false`.

```
consteval bool is_value(info r);
consteval bool is_object(info r);
```

46 *Returns*: `true` if `r` represents a value or object, respectively. Otherwise, `false`.

```
consteval bool is_structured_binding(info r);
```

47 *Returns*: `true` if `r` represents a structured binding. Otherwise, `false`.

```
consteval bool is_class_member(info r);
consteval bool is_namespace_member(info r);
consteval bool is_nonstatic_data_member(info r);
consteval bool is_static_member(info r);
consteval bool is_base(info r);
```

48 *Returns*: `true` if `r` represents a class member, namespace member, non-static data member, static member, or direct base class relationship, respectively. Otherwise, `false`.

```
consteval bool has_default_member_initializer(info r);
```

49 *Returns*: `true` if `r` represents a non-static data member that has a default member initializer. Otherwise, `false`.

```
consteval bool has_parent(info r);
```

50 *Returns*:

(50.1) — If `r` represents the global namespace, then `false`.

(50.2) — Otherwise, if `r` represents an entity that has C language linkage (9.12), then `false`.

(50.3) — Otherwise, if `r` represents an entity that has a language linkage other than C++ language linkage, then an implementation-defined value.

(50.4) — Otherwise, if `r` represents a type that is neither a class nor enumeration type, then `false`.

(50.5) — Otherwise, if `r` represents an entity or direct base class relationship, then `true`.

(50.6) — Otherwise, `false`.

```
consteval info parent_of(info r);
```

51 *Returns*:

(51.1) — If `r` represents a non-static data member that is a direct member of an anonymous union, or an unnamed bit-field declared within the *member-specification* of such a union, then a reflection representing the innermost enclosing anonymous union.

(51.2) — Otherwise, if `r` represents an enumerator, then a reflection representing the corresponding enumeration type.

(51.3) — Otherwise, if `r` represents a direct base class relationship (D, B), then a reflection representing D.

(51.4) — Otherwise, let E be a class, function, or namespace whose class scope, function parameter scope, or namespace scope, respectively, is the innermost such scope that either is, or encloses, the target scope of a declaration of what is represented by `r`.

(51.4.1) — If E is the function call operator of a closure type for a *consteval-block-declaration* (9.1), then `parent_of(parent_of(^^`E`))`.

[*Note 6*: In this case, the first `parent_of` will be the closure type, so the second `parent_of` is necessary to give the parent of that closure type. — *end note*]

(51.4.2) — Otherwise, `^^`E.

52 *Throws*: `meta::exception` unless `has_parent(r)` is `true`.

53 [*Example 4*:

```
struct I { };

struct F : I {
  union {
    int o;
  };

  enum N {
    A
  };
};

constexpr auto ctx = std::meta::access_context::current();

static_assert(parent_of(^^F) == ^^::);
static_assert(parent_of(bases_of(^^F, ctx)[0]) == ^^F);
static_assert(is_union_type(parent_of(^^F::o)));
static_assert(parent_of(^^F::N) == ^^F);
static_assert(parent_of(^^F::A) == ^^F::N);
```

— *end example*]

```
consteval info dealias(info r);
```

54 *Returns*: If `r` represents an entity, then a reflection representing the underlying entity of what `r` represents. Otherwise, `r`.

55 [*Example 5*:

```
using X = int;
using Y = X;
static_assert(dealias(^^int) == ^^int);
static_assert(dealias(^^X) == ^^int);
static_assert(dealias(^^Y) == ^^int);
```

— *end example*]

```
consteval bool has_template_arguments(info r);
```

56 *Returns*: `true` if `r` represents a specialization of a function template, variable template, class template, or an alias template. Otherwise, `false`.

```
consteval info template_of(info r);
```

57 *Returns*: A reflection of the template of the specialization represented by `r`.

58 *Throws*: `meta::exception` unless `has_template_arguments(r)` is `true`.

```
consteval vector<info> template_arguments_of(info r);
```

59 *Returns*: A `vector` containing reflections of the template arguments of the template specialization represented by `r`, in the order in which they appear in the corresponding template argument list. For a given template argument A, its corresponding reflection R is determined as follows:

(59.1) — If A denotes a type or type alias, then R is a reflection representing the underlying entity of A.

[*Note 7*: R always represents a type, never a type alias. — *end note*]

(59.2) — Otherwise, if A denotes a class template, variable template, concept, or alias template, then R is a reflection representing A.

(59.3) — Otherwise, A is a constant template argument (13.4.3). Let P be the corresponding template parameter.

(59.3.1) — If P has reference type, then R is a reflection representing the object or function referred to by A.

(59.3.2) — Otherwise, if P has class type, then R represents the corresponding template parameter object.

(59.3.3) — Otherwise, R is a reflection representing the value of A.

60 *Throws*: `meta::exception` unless `has_template_arguments(r)` is `true`.

61 [*Example 6*:

```
template<class T, class U = T> struct Pair { };
template<class T> struct Pair<char, T> { };
template<class T> using PairPtr = Pair<T*>;

static_assert(template_of(^^Pair<int>) == ^^Pair);
static_assert(template_of(^^Pair<char, char>) == ^^Pair);
static_assert(template_arguments_of(^^Pair<int>).size() == 2);
static_assert(template_arguments_of(^^Pair<int>)[0] == ^^int);

static_assert(template_of(^^PairPtr<int>) == ^^PairPtr);
static_assert(template_arguments_of(^^PairPtr<int>).size() == 1);

struct S { };
int i;
template<int, int&, S, template<class> class>
  struct X { };
constexpr auto T = ^^X<1, i, S{}, PairPtr>;
static_assert(is_value(template_arguments_of(T)[0]));
static_assert(is_object(template_arguments_of(T)[1]));
static_assert(is_object(template_arguments_of(T)[2]));
static_assert(template_arguments_of(T)[3] == ^^PairPtr);
```

— *end example*]

```
consteval vector<info> parameters_of(info r);
```

62 *Returns*:

(62.1) — If `r` represents a function F, then a `vector` containing reflections of the parameters of F, in the order in which they appear in a declaration of F.

(62.2) — Otherwise, `r` represents a function type T; a `vector` containing reflections of the types in parameter-type-list (9.3.4.6) of T, in the order in which they appear in the parameter-type-list.

63 *Throws*: `meta::exception` unless `r` represents a function or a function type.

```
consteval info variable_of(info r);
```

64 *Returns*: The reflection of the parameter variable corresponding to `r`.

65 *Throws*: `meta::exception` unless

(65.1) — `r` represents a parameter of a function F and

(65.2) — there is a point P in the evaluation context for which the innermost non-block scope enclosing P is the function parameter scope (6.4.4) associated with F.

```
consteval info return_type_of(info r);
```

66 *Returns*: The reflection of the return type of the function or function type represented by `r`.

67 *Throws*: `meta::exception` unless either `r` represents a function and *`has-type`*`(r)` is `true` or `r` represents a function type.

21.4.8 Scope identification [meta.reflection.scope]

1 The functions in this subclause retrieve information about where in the program they are invoked.

2 None of the functions in this subclause is an addressable function (16.4.5.2.1).

3 Given a program point P, let *`eval-point`*`(`P`)` be the following program point:

(3.1) — If a potentially-evaluated subexpression (6.10.1) of a default member initializer I for a member of class C (11.4.1) appears at P, then a point determined as follows:

(3.1.1) — If an aggregate initialization is using I, *eval-point*(Q), where Q is the point at which that aggregate initialization appears.

(3.1.2) — Otherwise, if an initialization by an inherited constructor (11.9.4) is using I, a point whose immediate scope is the class scope corresponding to C.

(3.1.3) — Otherwise, a point whose immediate scope is the function parameter scope corresponding to the constructor definition that is using I.

(3.2) — Otherwise, if a potentially-evaluated subexpression of a default argument (9.3.4.7) appears at P, *eval-point*(Q), where Q is the point at which the invocation of the function (7.6.1.3) using that default argument appears.

(3.3) — Otherwise, if the immediate scope of P is a function parameter scope introduced by a declaration D, and P appears either before the locus of D or within the trailing *requires-clause* of D, a point whose immediate scope is the innermost scope enclosing the locus of D that is not a template parameter scope.

(3.4) — Otherwise, if the immediate scope of P is a function parameter scope introduced by a *lambda-expression* L whose *lambda-introducer* appears at point Q, and P appears either within the *trailing-return-type* or the trailing *requires-clause* of L, *eval-point*(Q).

(3.5) — Otherwise, if the innermost non-block scope enclosing P is the function parameter scope introduced by a *consteval-block-declaration* (9.1), a point whose immediate scope is that inhabited by the outermost *consteval-block-declaration* D containing P such that each scope (if any) that intervenes between P and the function parameter scope introduced by D is either

(3.5.1) — a block scope or

(3.5.2) — a function parameter scope or lambda scope introduced by a *consteval-block-declaration*.

(3.6) — Otherwise, P.

4 Given a scope S, let *ctx-scope*(S) be the following scope:

(4.1) — If S is a class scope or namespace scope, S.

(4.2) — Otherwise, if S is a function parameter scope introduced by the declaration of a function, S.

(4.3) — Otherwise, if S is a lambda scope introduced by a *lambda-expression* L, the function parameter scope corresponding to the call operator of the closure type of L.

(4.4) — Otherwise, *ctx-scope*(S'), where S' is the parent scope of S.

5 Let *CURRENT-SCOPE*(P) for a point P be a reflection representing the function, class, or namespace whose corresponding function parameter scope, class scope, or namespace scope, respectively, is *ctx-scope*(S), where S is the immediate scope of *eval-point*(P).

```
consteval info current_function();
```

6 An invocation of `current_function` that appears at a program point P is value-dependent (13.8.3.4) if *eval-point*(P) is enclosed by a scope corresponding to a templated entity.

7 Let S be *CURRENT-SCOPE*(P), where P is the point at which the invocation of `current_function` lexically appears.

8 *Returns*: S.

9 *Throws*: `meta::exception` unless S represents a function.

```
consteval info current_class();
```

10 An invocation of `current_class` that appears at a program point P is value-dependent (13.8.3.4) if *eval-point*(P) is enclosed by a scope corresponding to a templated entity.

11 Let S be *CURRENT-SCOPE*(P) where P is the point at which the invocation of `current_class` lexically appears.

12 *Returns*: S if S represents a class. Otherwise, `parent_of`(S).

13 *Throws*: `meta::exception` unless S represents either a class or a member function.

```
consteval info current_namespace();
```

14 An invocation of `current_namespace` that appears at a program point P is value-dependent (13.8.3.4) if *`eval-point`*`(`P`)` is enclosed by a scope corresponding to a templated entity.

15 Let S be *`CURRENT-SCOPE`*`(`P`)` where P is the point at which the invocation of `current_namespace` lexically appears.

16 *Returns*: S if S represents a namespace. Otherwise, a reflection representing the nearest enclosing namespace of the entity represented by S.

21.4.9 Access control context [meta.reflection.access.context]

1 The class `access_context` represents a namespace, class, or function from which queries pertaining to access rules may be performed, as well as the designating class (11.8.3), if any.

2 An `access_context` has an associated scope and designating class.

```
namespace std::meta {
  struct access_context {
    access_context() = delete;

    consteval info scope() const;
    consteval info designating_class() const;

    static consteval access_context current() noexcept;
    static consteval access_context unprivileged() noexcept;
    static consteval access_context unchecked() noexcept;
    consteval access_context via(info cls) const;
  };
}
```

3 The type `access_context` is a structural, consteval-only, non-aggregate type. Two values `ac1` and `ac2` of type `access_context` are template-argument-equivalent (13.6) if `ac1.scope()` and `ac2.scope()` are template-argument-equivalent and `ac1.designating_class()` and `ac2.designating_class()` are template-argument-equivalent.

```
consteval info scope() const;
consteval info designating_class() const;
```

4 *Returns*: The `access_context`'s associated scope and designating class, respectively.

```
static consteval access_context current() noexcept;
```

5 *Returns*: An `access_context` whose designating class is the null reflection and whose scope is *`CURRENT-SCOPE`*`(`P`)`, where P is the point at which the invocation of `current` lexically appears.

6 *Remarks*: `current` is not an addressable function (16.4.5.2.1). An invocation of `current` that appears at a program point P is value-dependent (13.8.3.4) if *`eval-point`*`(`P`)` is enclosed by a scope corresponding to a templated entity.

7 [*Example 1*:

```
struct A {
  int a = 0;
  consteval A(int p) : a(p) {}
};
struct B : A {
  using A::A;
  consteval B(int p, int q) : A(p * q) {}
  info s = access_context::current().scope();
};
struct C : B { using B::B; };

struct Agg {
  consteval bool eq(info rhs = access_context::current().scope()) {
    return s == rhs;
  }
  info s = access_context::current().scope();
};
```

```
namespace NS {
  static_assert(Agg{}.s == access_context::current().scope());
  static_assert(Agg{}.eq());
  static_assert(B(1).s == ^^B);
  static_assert(is_constructor(B{1, 2}.s) && parent_of(B{1, 2}.s) == ^^B);
  static_assert(is_constructor(C{1, 2}.s) && parent_of(C{1, 2}.s) == ^^B);

  auto fn() -> [:is_namespace(access_context::current().scope()) ? ^^int : ^^bool:];
  static_assert(type_of(^^fn) == ^^auto()->int);

  template<auto R>
    struct TCls {
      consteval bool fn()
        requires (is_type(access_context::current().scope())) {
          return true;                  // OK, scope is TCls<R>.
        }
    };
  static_assert(TCls<0>{}.fn());
}
```

— *end example*]

```
static consteval access_context unprivileged() noexcept;
```

8 *Returns*: An `access_context` whose designating class is the null reflection and whose scope is the global namespace.

```
static consteval access_context unchecked() noexcept;
```

9 *Returns*: An `access_context` whose designating class and scope are both the null reflection.

```
consteval access_context via(info cls) const;
```

10 *Returns*: An `access_context` whose scope is `this->scope()` and whose designating class is `cls`.

11 *Throws*: `meta::exception` unless `cls` is either the null reflection or a reflection of a complete class type.

21.4.10 Member accessibility queries [meta.reflection.access.queries]

```
consteval bool is_accessible(info r, access_context ctx);
```

1 Let *PARENT-CLS*`(r)` be:

(1.1) — If `parent_of(r)` represents a class C, then C.

(1.2) — Otherwise, *PARENT-CLS*`(parent_of(r))`.

2 Let *DESIGNATING-CLS*`(r, ctx)` be:

(2.1) — If `ctx.designating_class()` represents a class C, then C.

(2.2) — Otherwise, *PARENT-CLS*`(r)`.

3 *Returns*:

(3.1) — If `r` represents an unnamed bit-field F, then `is_accessible(`$\texttt{r}_H$`, ctx)`, where $\texttt{r}_H$ represents a hypothetical non-static data member of the class represented by *PARENT-CLS*`(r)` with the same access as F.

[*Note 1*: Unnamed bit-fields are treated as class members for the purpose of `is_accessible`. — *end note*]

(3.2) — Otherwise, if `r` does not represent a class member or a direct base class relationship, then `true`.

(3.3) — Otherwise, if `r` represents

(3.3.1) — a class member that is not a (possibly indirect or variant) member of *DESIGNATING-CLS*`(r, ctx)` or

(3.3.2) — a direct base class relationship such that `parent_of(r)` does not represent *DESIGNATING-CLS*`(r, ctx)` or a (direct or indirect) base class thereof,

then `false`.

(3.4) — Otherwise, if `ctx.scope()` is the null reflection, then `true`.

(3.5) — Otherwise, letting P be a program point whose immediate scope is the function parameter scope, class scope, or namespace scope corresponding to the function, class, or namespace represented by `ctx.scope()`:

(3.5.1) — If `r` represents a direct base class relationship (D, B), then `true` if base class B of *`DESIGNATING-CLS`*`(r, ctx)` is accessible at P (11.8.3); otherwise `false`.

(3.5.2) — Otherwise, `r` represents a class member M; `true` if M would be accessible at P with the designating class (11.8.3) as *`DESIGNATING-CLS`*`(r, ctx)` if the effect of any *using-declaration*s (9.10) were ignored. Otherwise, `false`.

[*Note 2*: The definitions of when a class member or base class is accessible from a point P do not consider whether a declaration of that entity is reachable from P. — *end note*]

4 *Throws*: `meta::exception` if `r` represents a class member for which *`PARENT-CLS`*`(r)` is an incomplete class.

5 [*Example 1*:

```
consteval access_context fn() {
  return access_context::current();
}

class Cls {
  int mem;
  friend consteval access_context fn();
public:
  static constexpr auto r = ^^mem;
};

static_assert(is_accessible(Cls::r, fn()));
static_assert(!is_accessible(Cls::r, access_context::current()));
static_assert(is_accessible(Cls::r, access_context::unchecked()));
```

— *end example*]

```
consteval bool has_inaccessible_nonstatic_data_members(info r, access_context ctx);
```

6 *Returns*: `true` if `is_accessible(`R`, ctx)` is `false` for any R in `nonstatic_data_members_of(r, access_context::unchecked())`. Otherwise, `false`.

7 *Throws*: `meta::exception` if

(7.1) — the evaluation of `nonstatic_data_members_of(r, access_context::unchecked())` would exit via an exception or

(7.2) — `r` represents a closure type.

```
consteval bool has_inaccessible_bases(info r, access_context ctx);
```

8 *Returns*: `true` if `is_accessible(`R`, ctx)` is `false` for any R in `bases_of(r, access_context::unchecked())`. Otherwise, `false`.

9 *Throws*: `meta::exception` if the evaluation of `bases_of(r, access_context::unchecked())` would exit via an exception.

```
consteval bool has_inaccessible_subobjects(info r, access_context ctx);
```

10 *Effects*: Equivalent to:

```
return has_inaccessible_bases(r, ctx) || has_inaccessible_nonstatic_data_members(r, ctx);
```

21.4.11 Reflection member queries [meta.reflection.member.queries]

```
consteval vector<info> members_of(info r, access_context ctx);
```

1 A declaration D *members-of-precedes* a point P if D precedes either P or the point immediately following the *class-specifier* of the outermost class for which P is in a complete-class context.

2 A declaration D of a member M of a class or namespace Q is *Q-members-of-eligible* if

(2.1) — the host scope of D (6.4.1) is the class scope or namespace scope associated with Q,

(2.2) — D is not a friend declaration,

(2.3) — M is not a closure type (7.5.6.2),

(2.4) — M is not a specialization of a template (13.1),

(2.5) — if Q is a class that is not a closure type, then M is a direct member of Q (11.4.1) that is not a variant member of a nested anonymous union of Q (11.5.2), and

(2.6) — if Q is a closure type, then M is a function call operator or function call operator template.

It is implementation-defined whether declarations of other members of a closure type Q are Q-members-of-eligible.

3 A member M of a class or namespace Q is *Q-members-of-representable* from a point P if a Q-members-of-eligible declaration of M members-of-precedes P, and M is

(3.1) — a class or enumeration type,

(3.2) — a type alias,

(3.3) — a class template, function template, variable template, alias template, or concept,

(3.4) — a variable or reference V for which the type of V does not contain an undeduced placeholder type,

(3.5) — a function F for which

(3.5.1) — the type of F does not contain an undeduced placeholder type,

(3.5.2) — the constraints (if any) of F are satisfied, and

(3.5.3) — if F is a prospective destructor, F is the selected destructor (11.4.7),

(3.6) — a non-static data member,

(3.7) — a namespace, or

(3.8) — a namespace alias.

[*Note 1*: Examples of direct members that are not Q-members-of-representable for any entity Q include: unscoped enumerators (9.8), partial specializations of templates (13.7.6), and closure types (7.5.6.2). — *end note*]

4 *Returns*: A `vector` containing reflections of all members M of the entity Q represented by `dealias(r)` for which

(4.1) — M is Q-members-of-representable from some point in the evaluation context and

(4.2) — `is_accessible(^^`M`, ctx)` is `true`.

If `dealias(r)` represents a class C, then the `vector` also contains reflections representing all unnamed bit-fields B whose declarations inhabit the class scope corresponding to C for which `is_accessible(^^`B`, ctx)` is `true`. Reflections of class members and unnamed bit-fields that are declared appear in the order in which they are declared.

[*Note 2*: Base classes are not members. Implicitly-declared special members appear after any user-declared members (11.4.4). — *end note*]

5 *Throws*: `meta::exception` unless `dealias(r)` is a reflection representing either a class type that is complete from some point in the evaluation context or a namespace.

6 [*Example 1*:

```
// TU1
export module M;
namespace NS {
  export int m;
  static int l;
}
static_assert(members_of(^^NS, access_context::current()).size() == 2);

// TU2
import M;

static_assert(                                          // NS::l does not precede
  members_of(^^NS, access_context::current()).size() == 1);     // the constant-expression (6.5)

class B {};
```

```
struct S : B {
private:
  class I;
public:
  int m;
};

static_assert(                                                  // 6 special members,
  members_of(^^S, access_context::current()).size() == 7);      // 1 public member,
                                                                // does not include base

static_assert(                                                  // all of the above,
  members_of(^^S, access_context::unchecked()).size() == 8);    // as well as a reflection
                                                                // representing S::I
```

— *end example*]

```
consteval vector<info> bases_of(info type, access_context ctx);
```

7 *Returns*: Let C be the class represented by `dealias(type)`. A `vector` containing the reflections of all the direct base class relationships B, if any, of C such that `is_accessible(^^`B`, ctx)` is `true`. The direct base class relationships appear in the order in which the corresponding base classes appear in the *base-specifier-list* of C.

8 *Throws*: `meta::exception` unless `dealias(type)` represents a class type that is complete from some point in the evaluation context.

```
consteval vector<info> static_data_members_of(info type, access_context ctx);
```

9 *Returns*: A `vector` containing each element `e` of `members_of(type, ctx)` such that `is_variable(e)` is `true`, preserving their order.

10 *Throws*: `meta::exception` unless `dealias(type)` represents a class type that is complete from some point in the evaluation context.

```
consteval vector<info> nonstatic_data_members_of(info type, access_context ctx);
```

11 *Returns*: A `vector` containing each element `e` of `members_of(type, ctx)` such that `is_nonstatic_data_member(e)` is `true`, preserving their order.

12 *Throws*: `meta::exception` unless `dealias(type)` represents a class type that is complete from some point in the evaluation context.

```
consteval vector<info> subobjects_of(info type, access_context ctx);
```

13 *Returns*: A `vector` containing each element of `bases_of(type, ctx)` followed by each element of `nonstatic_data_members_of(type, ctx)`, preserving their order.

14 *Throws*: `meta::exception` unless `dealias(type)` represents a class type that is complete from some point in the evaluation context.

```
consteval vector<info> enumerators_of(info type_enum);
```

15 *Returns*: A `vector` containing the reflections of each enumerator of the enumeration represented by `dealias(type_enum)`, in the order in which they are declared.

16 *Throws*: `meta::exception` unless `dealias(type_enum)` represents an enumeration type, and `is_enumerable_type(type_enum)` is `true`.

21.4.12 Reflection layout queries [meta.reflection.layout]

```
struct member_offset {
  ptrdiff_t bytes;
  ptrdiff_t bits;
  constexpr ptrdiff_t total_bits() const;
  auto operator<=>(const member_offset&) const = default;
};
```

```
constexpr ptrdiff_t member_offset::total_bits() const;
```

1 *Returns*: `bytes * CHAR_BIT + bits`.

```
consteval member_offset offset_of(info r);
```

2 Let V be the offset in bits from the beginning of a complete object of the type represented by `parent_of(r)` to the subobject associated with the construct represented by `r`.

3 *Returns*: {V `/ CHAR_BIT,` V `% CHAR_BIT`}.

4 *Throws*: `meta::exception` unless `r` represents a non-static data member, unnamed bit-field, or direct base class relationship (D, B) for which either B is not a virtual base class or D is not an abstract class.

```
consteval size_t size_of(info r);
```

5 *Returns*: If

(5.1) — `r` represents a non-static data member of type T or a data member description (T, N, A, W, NUA, ANN) or

(5.2) — `dealias(r)` represents a type T,

then `sizeof(`T`)` if T is not a reference type and `size_of(add_pointer(^^`T`))` otherwise. Otherwise, `size_of(type_of(r))`.

[*Note 1*: It is possible that while `sizeof(char) == size_of(^^char)` is `true`, that `sizeof(char&) == size_of(^^char&)` is `false`. If `b` represents a direct base class relationship of an empty base class, then `size_of(b) > 0` is `true`. — *end note*]

6 *Throws*: `meta::exception` unless all of the following conditions are met:

(6.1) — `dealias(r)` is a reflection of a type, object, value, variable of non-reference type, non-static data member that is not a bit-field, direct base class relationship, or data member description (T, N, A, W, NUA, ANN) (11.4.1) where W is $\bot$.

(6.2) — If `dealias(r)` represents a type, then `is_complete_type(r)` is `true`.

```
consteval size_t alignment_of(info r);
```

7 *Returns*:

(7.1) — If `dealias(r)` represents a type T, then `alignment_of(add_pointer(r))` if T is a reference type and the alignment requirement of T otherwise.

(7.2) — Otherwise, if `dealias(r)` represents a variable or object, then the alignment requirement of the variable or object.

(7.3) — Otherwise, if `r` represents a direct base class relationship, then `alignment_of(type_of(r))`.

(7.4) — Otherwise, if `r` represents a non-static data member M of a class C, then the alignment of the direct member subobject corresponding to M of a complete object of type C.

(7.5) — Otherwise, `r` represents a data member description (T, N, A, W, NUA, ANN) (11.4.1). If A is not $\bot$, then the value A. Otherwise, `alignment_of(^^`T`)`.

8 *Throws*: `meta::exception` unless all of the following conditions are met:

(8.1) — `dealias(r)` is a reflection of a type, object, variable of non-reference type, non-static data member that is not a bit-field, direct base class relationship, or data member description (T, N, A, W, NUA, ANN) (11.4.1) where W is $\bot$.

(8.2) — If `dealias(r)` represents a type, then `is_complete_type(r)` is `true`.

```
consteval size_t bit_size_of(info r);
```

9 *Returns*:

(9.1) — If `r` represents an unnamed bit-field or a non-static data member that is a bit-field with width W, then W.

(9.2) — Otherwise, if `r` represents a data member description (T, N, A, W, NUA, ANN) (11.4.1) and W is not $\bot$, then W.

(9.3) — Otherwise, `CHAR_BIT * size_of(r)`.

10 *Throws*: `meta::exception` unless all of the following conditions are met:

(10.1) — `dealias(r)` is a reflection of a type, object, value, variable of non-reference type, non-static data member, unnamed bit-field, direct base class relationship, or data member description.

(10.2) — If `dealias(r)` represents a type, then `is_complete_type(r)` is `true`.

21.4.13 Annotation reflection [meta.reflection.annotation]

```
consteval vector<info> annotations_of(info item);
```

1 For a function F, let $S(F)$ be the set of declarations, ignoring any explicit instantiations, that declare either F or a templated function of which F is a specialization.

2 *Returns*: A `vector` containing all of the reflections R representing each annotation applying to:

(2.1) — if `item` represents a function parameter P of a function F, then the declaration of P in each declaration of F in $S(F)$,

(2.2) — otherwise, if `item` represents a function F, then each declaration of F in $S(F)$,

(2.3) — otherwise, if `item` represents a direct base class relationship (D, B), then the corresponding *base-specifier* in the definition of D,

(2.4) — otherwise, each declaration of the entity represented by `item`,

such that each specified declaration is reachable from either some point in the evaluation context (7.7.6) or a point immediately following the *class-specifier* of the outermost class for which such a point is in a complete-class context. For any two reflections R_1 and R_2 in the returned `vector`, if the annotation represented by R_1 precedes the annotation represented by R_2, then R_1 appears before R_2. If R_1 and R_2 represent annotations from the same translation unit T, any element in the returned `vector` between R_1 and R_2 represents an annotation from T.

[*Note 1*: The order in which two annotations appear is otherwise unspecified. — *end note*]

3 *Throws*: `meta::exception` unless `item` represents a type, type alias, variable, function, function parameter, namespace, enumerator, direct base class relationship, or non-static data member.

4 [*Example 1*:

```
[[=1]] void f();
[[=2, =3]] void g();
void g [[=4]] ();

static_assert(annotations_of(^^f).size() == 1);
static_assert(annotations_of(^^g).size() == 3);
static_assert([: constant_of(annotations_of(^^g)[0]) :] == 2);
static_assert(extract<int>(annotations_of(^^g)[1]) == 3);
static_assert(extract<int>(annotations_of(^^g)[2]) == 4);

struct Option { bool value; };

struct C {
  [[=Option{true}]] int a;
  [[=Option{false}]] int b;
};

static_assert(extract<Option>(annotations_of(^^C::a)[0]).value);
static_assert(!extract<Option>(annotations_of(^^C::b)[0]).value);

template<class T>
  struct [[=42]] D { };

constexpr std::meta::info a1 = annotations_of(^^D<int>)[0];
constexpr std::meta::info a2 = annotations_of(^^D<char>)[0];
static_assert(a1 != a2);
static_assert(constant_of(a1) == constant_of(a2));

[[=1]] int x, y;
static_assert(annotations_of(^^x)[0] == annotations_of(^^y)[0]);
```

— *end example*]

```
consteval vector<info> annotations_of_with_type(info item, info type);
```

Returns: A `vector` containing each element `e` of `annotations_of(item)` where

```
remove_const(type_of(e)) == remove_const(type)
```

is `true`, preserving their order.

Throws: `meta::exception` unless

(6.1) — the evaluation of `annotations_of(item)` would not exit via an exception and

(6.2) — `dealias(type)` represents a type and `is_complete_type(type)` is `true`.

21.4.14 Value extraction [meta.reflection.extract]

The `extract` function template may be used to extract a value out of a reflection when its type is known.

The following are defined for exposition only to aid in the specification of `extract`.

```
template<class T>
  consteval T extract-ref(info r);        // exposition only
```

[*Note 1*: `T` is a reference type. — *end note*]

Returns: If `r` represents an object O, then a reference to O. Otherwise, a reference to the object declared, or referred to, by the variable represented by `r`.

Throws: `meta::exception` unless

(5.1) — `r` represents a variable or object of type `U`,

(5.2) — `is_convertible_v<remove_reference_t<U>(*)[], remove_reference_t<T>(*)[]>` is `true`, and

[*Note 2*: The intent is to allow only qualification conversion from `U` to `T`. — *end note*]

(5.3) — If `r` represents a variable, then either that variable is usable in constant expressions or its lifetime began within the core constant expression currently under evaluation.

```
template<class T>
  consteval T extract-member-or-function(info r);        // exposition only
```

Returns:

(6.1) — If `T` is a pointer type, then a pointer value pointing to the function represented by `r`.

(6.2) — Otherwise, a pointer-to-member value designating the non-static data member or function represented by `r`.

Throws: `meta::exception` unless

(7.1) — `r` represents a non-static data member with type `X`, that is not a bit-field, that is a direct member of class `C`, `T` and `X C::*` are similar types (7.3.6), and `is_convertible_v<X C::*, T>` is `true`;

(7.2) — `r` represents an implicit object member function with type `F` or `F noexcept` that is a direct member of a class `C`, and `T` is `F C::*`; or

(7.3) — `r` represents a non-member function, static member function, or explicit object member function of function type `F` or `F noexcept`, and `T` is `F*`.

```
template<class T>
  consteval T extract-value(info r);        // exposition only
```

Let `U` be the type of the value or object that `r` represents.

Returns: `static_cast<T>([:`R`:])`, where R is a constant expression of type `info` such that R `== r` is `true`.

Throws: `meta::exception` unless

(10.1) — `U` is a pointer type, `T` and `U` are either similar (7.3.6) or both function pointer types, and `is_convertible_v<U, T>` is `true`,

(10.2) — `U` is not a pointer type and the cv-unqualified types of `T` and `U` are the same,

(10.3) — `U` is an array type, `T` is a pointer type, `remove_extent_t<U>*` and `T` are similar types, and the value `r` represents is convertible to `T`, or

(10.4) — `U` is a closure type, `T` is a function pointer type, and the value that `r` represents is convertible to `T`.

```
template<class T>
  consteval T extract(info r);
```

11 Let `U` be `remove_cv_t<T>`.

12 *Effects*: Equivalent to:

```
if constexpr (is_reference_type(^^T)) {
  return extract-ref<T>(r);
} else if (is_nonstatic_data_member(r) || is_function(r)) {
  return extract-member-or-function<U>(r);
} else {
  return extract-value<U>(constant_of(r));
}
```

21.4.15 Reflection substitution [meta.reflection.substitute]

1 Let *TARG-SPLICE*`(x)` be:

(1.1) — `template [: x :]` if `is_template(x)` is `true`, otherwise

(1.2) — `typename [: x :]` if `is_type(x)` is `true`, otherwise

(1.3) — `([: x :])`.

```
template<class R>
concept reflection_range =
  ranges::input_range<R> &&
  same_as<ranges::range_value_t<R>, info> &&
  same_as<remove_cvref_t<ranges::range_reference_t<R>>, info>;

template<reflection_range R = initializer_list<info>>
  consteval bool can_substitute(info templ, R&& arguments);
```

2 Let `Z` be the template represented by `templ` and let `Args...` be a sequence of prvalue constant expressions that compute the reflections held by the elements of `arguments`, in order.

3 *Returns*: `true` if `Z<`*TARG-SPLICE*`(Args)...>` is a valid *template-id* (13.3) that does not name a function whose type contains an undeduced placeholder type. Otherwise, `false`.

4 *Throws*: `meta::exception` unless `templ` represents a template, and every reflection in `arguments` represents a construct usable as a template argument (13.4).

5 [*Note 1*: If forming `Z<`*TARG-SPLICE*`(Args)...>` leads to a failure outside of the immediate context, the program is ill-formed. — *end note*]

```
template<reflection_range R = initializer_list<info>>
  consteval info substitute(info templ, R&& arguments);
```

6 Let `Z` be the template represented by `templ` and let `Args...` be a sequence of prvalue constant expressions that compute the reflections held by the elements of `arguments`, in order.

7 *Returns*: `^^Z<`*TARG-SPLICE*`(Args)...>`.

8 *Throws*: `meta::exception` unless `can_substitute(templ, arguments)` is `true`.

9 [*Note 2*: If forming `Z<`*TARG-SPLICE*`(Args)...>` leads to a failure outside of the immediate context, the program is ill-formed. — *end note*]

10 [*Example 1*:

```
template<class T>
  auto fn1();

static_assert(!can_substitute(^^fn1, {^^int}));
constexpr info r1 = substitute(^^fn1, {^^int});        // error: fn1<int> contains an undeduced
                                                       // placeholder type for its return type
```

```
template<class T>
  auto fn2() {
    static_assert(^^T != ^^int);                    // static assertion failed during
                                                    // instantiation of fn2<int>
    return 0;
  }

constexpr bool r2 = can_substitute(^^fn2, {^^int});     // error: instantiation of body of fn2<int>
                                                        // is needed to deduce return type
```

— *end example*]

11 [*Example 2*:

```
consteval info to_integral_constant(unsigned i) {
  return substitute(^^integral_constant, {^^unsigned, reflect_constant(i)});
}
constexpr info r = to_integral_constant(2);             // OK, r represents the type
                                                        // integral_constant<unsigned, 2>
```

— *end example*]

21.4.16 Expression result reflection [meta.reflection.result]

```
template<class T>
  consteval info reflect_constant(T expr);
```

1 *Mandates*: `is_copy_constructible_v<T>` is `true` and `T` is a cv-unqualified structural type (13.2) that is not a reference type.

2 Let V be:

(2.1) — if `T` is a class type, then an object that is template-argument-equivalent to the value of `expr`;

(2.2) — otherwise, the value of `expr`.

3 Let `TCls` be the invented template:

```
template<T P> struct TCls;
```

4 *Returns*: `template_arguments_of(^^TCls<`V`>)[0]`.

[*Note 1*: This is a reflection of an object for class types, and a reflection of a value otherwise. — *end note*]

5 *Throws*: `meta::exception` unless the *template-id* `TCls<`V`>` would be valid.

6 [*Example 1*:

```
template<auto D>
  struct A { };

struct N { int x; };
struct K { char const* p; };

constexpr info r1 = reflect_constant(42);
static_assert(is_value(r1));
static_assert(r1 == template_arguments_of(^^A<42>)[0]);

constexpr info r2 = reflect_constant(N{42});
static_assert(is_object(r2));
static_assert(r2 == template_arguments_of(^^A<N{42}>)[0]);

constexpr info r3 = reflect_constant(K{nullptr});
constexpr info r4 = reflect_constant(K{"ebab"});        // error: constituent pointer
                                                        // points to string literal
```

— *end example*]

```
template<class T>
  consteval info reflect_object(T& expr);
```

7 *Mandates*: `T` is an object type.

8 *Returns*: A reflection of the object designated by `expr`.

9 *Throws*: `meta::exception` if `E` is not suitable for use as a constant template argument for a constant template parameter of type `T&` (13.4.3), where `E` is an lvalue constant expression that computes the object that `expr` refers to.

```
template<class T>
  consteval info reflect_function(T& fn);
```

10 *Mandates*: `T` is a function type.

11 *Returns*: A reflection of the function designated by `fn`.

12 *Throws*: `meta::exception` if `F` is not suitable for use as a constant template argument for a constant template parameter of type `T&` (13.4.3), where `F` is an lvalue constant expression that computes the function that `fn` refers to.

21.4.17 Reflection class definition generation [meta.reflection.define.aggregate]

```
namespace std::meta {
  struct data_member_options {
    struct name-type {                          // exposition only
      template<class T>
        requires constructible_from<u8string, T>
        consteval name-type(T&&);

      template<class T>
        requires constructible_from<string, T>
        consteval name-type(T&&);

    private:
      variant<u8string, string> contents;       // exposition only
    };

    optional<name-type> name;
    optional<int> alignment;
    optional<int> bit_width;
    bool no_unique_address = false;
    vector<info> annotations;
  };
}
```

1 The classes `data_member_options` and `data_member_options::name-type` are consteval-only types (6.9.1), and are not structural types (13.2).

```
template<class T>
  requires constructible_from<u8string, T>
  consteval name-type(T&& value);
```

2 *Effects*: Initializes *contents* with `u8string(std::forward<T>(value))`.

```
template<class T>
  requires constructible_from<string, T>
  consteval name-type(T&& value);
```

3 *Effects*: Initializes *contents* with `string(std::forward<T>(value))`.

[*Note 1*: The class *name-type* allows the function `data_member_spec` to accept an ordinary string literal (or `string_view`, `string`, etc.) or a UTF-8 string literal (or `u8string_view`, `u8string`, etc.) equally well.

[*Example 1*:

```
consteval void fn() {
  data_member_options o1 = {.name = "ordinary_literal_encoding"};
  data_member_options o2 = {.name = u8"utf8_encoding"};
}
```

— *end example*]

— *end note*]

```
consteval info data_member_spec(info type, data_member_options options);
```

4 *Returns*: A reflection of a data member description (T, N, A, W, NUA, ANN) (11.4.1) where

(4.1) — T is the type represented by `dealias(type)`,

(4.2) — N is either the identifier encoded by `options.name` or $\perp$ if `options.name` does not contain a value,

(4.3) — A is either the alignment value held by `options.alignment` or $\perp$ if `options.alignment` does not contain a value,

(4.4) — W is either the value held by `options.bit_width` or $\perp$ if `options.bit_width` does not contain a value,

(4.5) — NUA is the value held by `options.no_unique_address`, and

(4.6) — ANN is the sequence of values `constant_of(r)` for each `r` in `options.annotations`.

[*Note 2*: The returned reflection value is primarily useful in conjunction with `define_aggregate`; it can also be queried by certain other functions in `std::meta` (e.g., `type_of`, `identifier_of`). — *end note*]

5 *Throws*: `meta::exception` unless the following conditions are met:

(5.1) — `dealias(type)` represents either an object type or a reference type;

(5.2) — if `options.name` contains a value, then:

(5.2.1) — `holds_alternative<u8string>(options.name->`*`contents`*`)` is `true` and `get<u8string>(options.name->`*`contents`*`)` contains the spelling of a valid *token* that is an *identifier* (5.11) when interpreted with UTF-8, or

(5.2.2) — `holds_alternative<string>(options.name->`*`contents`*`)` is `true` and `get<string>(options.name->`*`contents`*`)` contains the spelling of a valid *token* that is an *identifier* (5.11) when interpreted with the ordinary literal encoding;

[*Note 3*: Lexical constructs like *universal-character-name*s (5.3.2) are not processed. For example, `R"(\u03B1)"` is an invalid identifier and is not interpreted as `"`α`"`. — *end note*]

(5.3) — if `options.name` does not contain a value, then `options.bit_width` contains a value and `options.annotations` is empty;

(5.4) — if `options.bit_width` contains a value V, then

(5.4.1) — `is_integral_type(type) || is_enum_type(type)` is `true`,

(5.4.2) — `options.alignment` does not contain a value,

(5.4.3) — `options.no_unique_address` is `false`,

(5.4.4) — V is not negative, and

(5.4.5) — if V equals `0`, then `options.name` does not contain a value; and

(5.4.6) — if `options.name` does not contain a value, then `is_const(type) || is_volatile(type)` is `false`; and

(5.5) — if `options.alignment` contains a value, it is an alignment value (6.8.3) not less than `alignment_of(type)`; and

(5.6) — for every reflection `r` in `options.annotations`, *`has-type`*`(r)` is `true`, `type_of(r)` represents a non-array object type, and evaluation of `constant_of(r)` does not exit via an exception.

```
consteval bool is_data_member_spec(info r);
```

6 *Returns*: `true` if `r` represents a data member description. Otherwise, `false`.

```
template<reflection_range R = initializer_list<info>>
  consteval info define_aggregate(info class_type, R&& mdescrs);
```

7 Let C be the type represented by `class_type` and r_K be the K^{th} reflection value in `mdescrs`. For every r_K in `mdescrs`, let $(T_K, N_K, A_K, W_K, NUA_K, ANN_K)$ be the corresponding data member description represented by r_K.

8 *Constant When*:

(8.1) — `class_type` represents a cv-unqualified class type;

(8.2) — C is incomplete from every point in the evaluation context;

[*Note 4*: C can be a class template specialization for which there is a reachable definition of the class template. In this case, the injected declaration is an explicit specialization. — *end note*]

(8.3) — `is_data_member_spec(`r_K`)` is `true` for every r_K;

(8.4) — `is_complete_type(`T_K`)` is `true` for every r_K; and

(8.5) — for every pair (r_K, r_L) where $K < L$, if N_K is not $\perp$ and N_L is not $\perp$, then either:

(8.5.1) — N_K is not the same identifier as N_L or

(8.5.2) — N_K is the identifier `_` (U+005F low line).

[*Note 5*: Every provided identifier is unique or `"_"`. — *end note*]

9 *Effects*: Produces an injected declaration D (7.7.6) that defines C and has properties as follows:

(9.1) — The target scope of D is the scope to which C belongs (6.4.1).

(9.2) — The locus of D follows immediately after the core constant expression currently under evaluation.

(9.3) — The characteristic sequence of D (7.7.6) is the sequence of reflection values r_K.

(9.4) — If C is a specialization of a templated class T, and C is not a local class, then D is an explicit specialization of T.

(9.5) — For each r_K, there is a corresponding entity M_K with public access belonging to the class scope of D with the following properties:

(9.5.1) — If N_K is $\perp$, M_K is an unnamed bit-field. Otherwise, M_K is a non-static data member whose name is the identifier N_K.

(9.5.2) — The type of M_K is T_K.

(9.5.3) — M_K is declared with the attribute `[[no_unique_address]]` if and only if NUA_K is `true`.

(9.5.4) — If W_K is not $\perp$, M_K is a bit-field whose width is that value. Otherwise, M_K is not a bit-field.

(9.5.5) — If A_K is not $\perp$, M_K has the *alignment-specifier* `alignas(`A_K`)`. Otherwise, M_K has no *alignment-specifier*.

(9.5.6) — For every reflection `r` in ANN_K, M_K has an annotation whose underlying constant (9.13.12) is `r`.

(9.6) — For every r_L in `mdescrs` such that $K < L$, the declaration corresponding to r_K precedes the declaration corresponding to r_L.

10 *Returns*: `class_type`.

11 *Remarks*: If C is a specialization of a templated class and it has not been instantiated, C is treated as an explicit specialization.

21.4.18 Reflection type traits [meta.reflection.traits]

1 This subclause specifies `consteval` functions to query the properties of types (21.3.5), query the relationships between types (21.3.7), or transform types (21.3.8), during program translation. Each `consteval` function declared in this class has an associated class template declared elsewhere in this document.

2 Every function and function template declared in this subclause throws an exception of type `meta::exception` unless the following conditions are met:

(2.1) — For every parameter `p` of type `info`, `is_type(p)` is `true`.

(2.2) — For every parameter `r` whose type is constrained on `reflection_range`, `ranges::all_of(r, is_type)` is `true`.

```
// associated with 21.3.5.2, primary type categories

```

3 For a function or function template F defined in this subclause, let C be its associated class template. For the evaluation of a call to F, let S be the specialization of C in terms of which the call is specified.

(3.1) — If

(3.1.1) — the template arguments of S violate a condition specified in a *Mandates* element in the specification of C;

(3.1.2) — the call is specified to produce a reflection of a type, but S would have no member named `type`; or

(3.1.3) — the call is specified to return S`::value`, but that expression would not be a valid converted constant expression of type `R`, where `R` is the return type of F;

then an exception of type `meta::exception` is thrown.

[*Note 1*: For the first case, S is not instantiated. — *end note*]

(3.2) — Otherwise, if the instantiation of S would result in undefined behavior due to dependence on an incomplete type (21.3.2), then the call is not a constant subexpression.

(3.3) — Otherwise, if the template arguments of S do not meet the preconditions of C, then it is unspecified whether the call is a constant subexpression. If it is, the call produces the result that would be produced if C had no preconditions.

4 Each function or function template declared above has the following behavior based on the signature and return type of that function or function template.

[*Note 2*: The associated class template need not be instantiated. — *end note*]

Table 64 — Reflection type traits **[tab:meta.reflection.traits]**

Signature and Return Type	*Returns*
`bool meta::`*`UNARY`*`(info type);` `bool meta::`*`UNARY`*`_type(info type);`	`std::`*`UNARY`*`<`T`>::value`, where T is the type or type alias represented by `type`
`bool meta::`*`BINARY`*`(info t1, info t2);` `bool meta::`*`BINARY`*`_type(info t1, info t2);`	`std::`*`BINARY`*`<`T_1`, `T_2`>::value`, where T_1 and T_2 are the types or type aliases represented by `t1` and `t2`, respectively
`template<reflection_range R>` `bool meta::`*`VARIADIC`*`_type(info type, R&& args);`	`std::`*`VARIADIC`*`<`T`, `U`...>::value`, where T is the type or type alias represented by `type` and `U...` is the pack of types or type aliases whose elements are represented by the corresponding elements of `args`
`template<reflection_range R>` `bool meta::`*`VARIADIC`*`_type(info t1, info t2, R&& args);`	`std::`*`VARIADIC`*`<`T_1`, `T_2`, `U`...>::value`, where T_1 and T_2 are the types or type aliases represented by `t1` and `t2`, respectively, and U`...` is the pack of types or type aliases whose elements are represented by the corresponding elements of `args`
`info meta::`*`UNARY`*`(info type);`	A reflection representing the type denoted by `std::`*`UNARY`*`<`T`>::type`, where T is the type or type alias represented by `type`
`template<reflection_range R>` `info meta::`*`VARIADIC`*`(R&& args);`	A reflection representing the type denoted by `std::`*`VARIADIC`*`<`T`...>::type`, where T`...` is the pack of types or type aliases whose elements are represented by the corresponding elements of `args`

Table 64 — Reflection type traits (continued)

Signature and Return Type	*Returns*
`template<reflection_range R> info meta::VARIADIC(info type, R&& args);`	A reflection representing the type denoted by `std::VARIADIC<`T`, `U`...>::type`, where T is the type or type alias represented by `type` and U`...` is the pack of types or type aliases whose elements are represented by the corresponding elements of `args`

5 [*Note 3*: For those functions or function templates which return a reflection, that reflection always represents a type and never a type alias. — *end note*]

6 [*Note 4*: If `t` is a reflection of the type `int` and `u` is a reflection of an alias to the type `int`, then `t == u` is `false` but `is_same_type(t, u)` is `true`. Also, `t == dealias(u)` is `true`. — *end note*]

```
consteval size_t rank(info type);
```

7 *Returns*: `std::rank<`T`>::value`, where T is the type represented by `dealias(type)`.

```
consteval size_t extent(info type, unsigned i = 0);
```

8 *Returns*: `std::extent<`T`, `I`>::value`, where T is the type represented by `dealias(type)` and I is a constant equal to `i`.

```
consteval size_t tuple_size(info type);
```

9 *Returns*: `std::tuple_size<`T`>::value`, where T is the type represented by `dealias(type)`.

```
consteval info tuple_element(size_t index, info type);
```

10 *Returns*: A reflection representing the type denoted by `std::tuple_element<`I`, `T`>::type`, where T is the type represented by `dealias(type)` and I is a constant equal to `index`.

```
consteval size_t variant_size(info type);
```

11 *Returns*: `std::variant_size<`T`>::value`, where T is the type represented by `dealias(type)`.

```
consteval info variant_alternative(size_t index, info type);
```

12 *Returns*: A reflection representing the type denoted by `std::variant_alternative<`I`, `T`>::type`, where T is the type represented by `dealias(type)` and I is a constant equal to `index`.

```
consteval strong_ordering type_order(info t1, info t2);
```

13 *Returns*: `std::type_order<`T_1`, `T_2`>::value`, where T_1 and T_2 are the types represented by `dealias(t1)` and `dealias(t2)`, respectively.

21.5 Compile-time rational arithmetic [ratio]

21.5.1 General [ratio.general]

1 Subclause 21.5 describes the ratio library. It provides a class template `ratio` which exactly represents any finite rational number with a numerator and denominator representable by compile-time constants of type `intmax_t`.

2 Throughout subclause 21.5, the names of template parameters are used to express type requirements. If a template parameter is named `R1` or `R2`, and the template argument is not a specialization of the `ratio` template, the program is ill-formed.

21.5.2 Header `<ratio>` synopsis [ratio.syn]

```
// all freestanding
namespace std {
  // 21.5.3, class template ratio
  template<intmax_t N, intmax_t D = 1> class ratio;

  // 21.5.4, ratio arithmetic
  template<class R1, class R2> using ratio_add = see below;
  template<class R1, class R2> using ratio_subtract = see below;
  template<class R1, class R2> using ratio_multiply = see below;
  template<class R1, class R2> using ratio_divide = see below;
```

```
  // 21.5.5, ratio comparison
  template<class R1, class R2> struct ratio_equal;
  template<class R1, class R2> struct ratio_not_equal;
  template<class R1, class R2> struct ratio_less;
  template<class R1, class R2> struct ratio_less_equal;
  template<class R1, class R2> struct ratio_greater;
  template<class R1, class R2> struct ratio_greater_equal;

  template<class R1, class R2>
    constexpr bool ratio_equal_v = ratio_equal<R1, R2>::value;
  template<class R1, class R2>
    constexpr bool ratio_not_equal_v = ratio_not_equal<R1, R2>::value;
  template<class R1, class R2>
    constexpr bool ratio_less_v = ratio_less<R1, R2>::value;
  template<class R1, class R2>
    constexpr bool ratio_less_equal_v = ratio_less_equal<R1, R2>::value;
  template<class R1, class R2>
    constexpr bool ratio_greater_v = ratio_greater<R1, R2>::value;
  template<class R1, class R2>
    constexpr bool ratio_greater_equal_v = ratio_greater_equal<R1, R2>::value;

  // 21.5.6, convenience SI typedefs
  using quecto = ratio<1, 1'000'000'000'000'000'000'000'000'000'000>;     // see below

  using micro  = ratio<1,                                 1'000'000>;
  using milli  = ratio<1,                                     1'000>;
  using centi  = ratio<1,                                       100>;
  using deci   = ratio<1,                                        10>;
  using deca   = ratio<                                       10, 1>;
  using hecto  = ratio<                                      100, 1>;
  using kilo   = ratio<                                    1'000, 1>;
  using mega   = ratio<                                1'000'000, 1>;
  using giga   = ratio<                            1'000'000'000, 1>;
  using tera   = ratio<                        1'000'000'000'000, 1>;
  using peta   = ratio<                    1'000'000'000'000'000, 1>;
  using exa    = ratio<                1'000'000'000'000'000'000, 1>;
  using zetta  = ratio<            1'000'000'000'000'000'000'000, 1>;     // see below
  using yotta  = ratio<        1'000'000'000'000'000'000'000'000, 1>;     // see below
  using ronna  = ratio<    1'000'000'000'000'000'000'000'000'000, 1>;     // see below
  using quetta = ratio<1'000'000'000'000'000'000'000'000'000'000, 1>;     // see below
}
```

21.5.3 Class template `ratio` [ratio.ratio]

```
namespace std {
  template<intmax_t N, intmax_t D = 1> class ratio {
  public:
    static constexpr intmax_t num;
    static constexpr intmax_t den;
    using type = ratio<num, den>;
  };
}
```

1 If the template argument `D` is zero or the absolute values of either of the template arguments `N` and `D` is not representable by type `intmax_t`, the program is ill-formed.

[*Note 1*: These rules ensure that infinite ratios are avoided and that for any negative input, there exists a representable value of its absolute value which is positive. This excludes the most negative value. — *end note*]

2 The static data members `num` and `den` shall have the following values, where `gcd` represents the greatest common divisor of the absolute values of `N` and `D`:

(2.1) — `num` shall have the value sgn(`N`) `*` sgn(`D`) `*` `abs(N) / gcd`.

(2.2) — `den` shall have the value `abs(D) / gcd`.

21.5.4 Arithmetic on `ratios` [ratio.arithmetic]

1 Each of the alias templates `ratio_add`, `ratio_subtract`, `ratio_multiply`, and `ratio_divide` denotes the result of an arithmetic computation on two `ratios` `R1` and `R2`. With `X` and `Y` computed (in the absence of arithmetic overflow) as specified by Table 65, each alias denotes a `ratio<U, V>` such that `U` is the same as `ratio<X, Y>::num` and `V` is the same as `ratio<X, Y>::den`.

2 If it is not possible to represent `U` or `V` with `intmax_t`, the program is ill-formed. Otherwise, an implementation should yield correct values of `U` and `V`. If it is not possible to represent `X` or `Y` with `intmax_t`, the program is ill-formed unless the implementation yields correct values of `U` and `V`.

Table 65 — Expressions used to perform ratio arithmetic [tab:ratio.arithmetic]

Type	Value of `X`	Value of `Y`
`ratio_add<R1, R2>`	`R1::num * R2::den + R2::num * R1::den`	`R1::den * R2::den`
`ratio_subtract<R1, R2>`	`R1::num * R2::den - R2::num * R1::den`	`R1::den * R2::den`
`ratio_multiply<R1, R2>`	`R1::num * R2::num`	`R1::den * R2::den`
`ratio_divide<R1, R2>`	`R1::num * R2::den`	`R1::den * R2::num`

3 [*Example 1*:

```
static_assert(ratio_add<ratio<1, 3>, ratio<1, 6>>::num == 1, "1/3+1/6 == 1/2");
static_assert(ratio_add<ratio<1, 3>, ratio<1, 6>>::den == 2, "1/3+1/6 == 1/2");
static_assert(ratio_multiply<ratio<1, 3>, ratio<3, 2>>::num == 1, "1/3*3/2 == 1/2");
static_assert(ratio_multiply<ratio<1, 3>, ratio<3, 2>>::den == 2, "1/3*3/2 == 1/2");

// The following cases may cause the program to be ill-formed under some implementations
static_assert(ratio_add<ratio<1, INT_MAX>, ratio<1, INT_MAX>>::num == 2,
  "1/MAX+1/MAX == 2/MAX");
static_assert(ratio_add<ratio<1, INT_MAX>, ratio<1, INT_MAX>>::den == INT_MAX,
  "1/MAX+1/MAX == 2/MAX");
static_assert(ratio_multiply<ratio<1, INT_MAX>, ratio<INT_MAX, 2>>::num == 1,
  "1/MAX * MAX/2 == 1/2");
static_assert(ratio_multiply<ratio<1, INT_MAX>, ratio<INT_MAX, 2>>::den == 2,
  "1/MAX * MAX/2 == 1/2");
```

— *end example*]

21.5.5 Comparison of `ratios` [ratio.comparison]

```
template<class R1, class R2>
  struct ratio_equal : bool_constant<R1::num == R2::num && R1::den == R2::den> { };

template<class R1, class R2>
  struct ratio_not_equal : bool_constant<!ratio_equal_v<R1, R2>> { };

template<class R1, class R2>
  struct ratio_less : bool_constant<see below> { };
```

1 If `R1::num` × `R2::den` is less than `R2::num` × `R1::den`, `ratio_less<R1, R2>` shall be derived from `bool_constant<true>`; otherwise it shall be derived from `bool_constant<false>`. Implementations may use other algorithms to compute this relationship to avoid overflow. If overflow occurs, the program is ill-formed.

```
template<class R1, class R2>
  struct ratio_less_equal : bool_constant<!ratio_less_v<R2, R1>> { };

template<class R1, class R2>
  struct ratio_greater : bool_constant<ratio_less_v<R2, R1>> { };

template<class R1, class R2>
  struct ratio_greater_equal : bool_constant<!ratio_less_v<R1, R2>> { };
```

21.5.6 SI types for `ratio` [ratio.si]

1 For each of the *typedef-name*s `quecto`, `ronto`, `yocto`, `zepto`, `zetta`, `yotta`, `ronna`, and `quetta`, if both of the constants used in its specification are representable by `intmax_t`, the typedef is declared; if either of the constants is not representable by `intmax_t`, the typedef is not declared.

22 General utilities library [utilities]

22.1 General [utilities.general]

1 This Clause describes utilities that are generally useful in C++ programs; some of these utilities are used by other elements of the C++ standard library. These utilities are summarized in Table 66.

Table 66 — General utilities library summary [tab:utilities.summary]

	Subclause	Header
22.2	Utility components	`<utility>`
22.3	Pairs	
22.4	Tuples	`<tuple>`
22.5	Optional objects	`<optional>`
22.6	Variants	`<variant>`
22.7	Storage for any type	`<any>`
22.8	Expected objects	`<expected>`
22.9	Fixed-size sequences of bits	`<bitset>`
22.10	Function objects	`<functional>`
22.11	Bit manipulation	`<bit>`

22.2 Utility components [utility]

22.2.1 Header <utility> synopsis [utility.syn]

1 The header `<utility>` contains some basic function and class templates that are used throughout the rest of the library.

```
// all freestanding
#include <compare>              // see 17.12.1
#include <initializer_list>     // see 17.11.2

namespace std {
  // 22.2.2, swap
  template<class T>
    constexpr void swap(T& a, T& b) noexcept(see below);
  template<class T, size_t N>
    constexpr void swap(T (&a)[N], T (&b)[N]) noexcept(is_nothrow_swappable_v<T>);

  // 22.2.3, exchange
  template<class T, class U = T>
    constexpr T exchange(T& obj, U&& new_val) noexcept(see below);

  // 22.2.4, forward/move
  template<class T>
    constexpr T&& forward(remove_reference_t<T>& t) noexcept;
  template<class T>
    constexpr T&& forward(remove_reference_t<T>&& t) noexcept;
  template<class T, class U>
    constexpr auto forward_like(U&& x) noexcept -> see below;
  template<class T>
    constexpr remove_reference_t<T>&& move(T&&) noexcept;
  template<class T>
    constexpr conditional_t<
        !is_nothrow_move_constructible_v<T> && is_copy_constructible_v<T>, const T&, T&&>
      move_if_noexcept(T& x) noexcept;
```

```
// 22.2.5, as_const
template<class T>
  constexpr add_const_t<T>& as_const(T& t) noexcept;
template<class T>
  void as_const(const T&&) = delete;

// 22.2.6, declval
template<class T>
  add_rvalue_reference_t<T> declval() noexcept;    // as unevaluated operand

// 22.2.7, integer comparison functions
template<class T, class U>
  constexpr bool cmp_equal(T t, U u) noexcept;
template<class T, class U>
  constexpr bool cmp_not_equal(T t, U u) noexcept;

template<class T, class U>
  constexpr bool cmp_less(T t, U u) noexcept;
template<class T, class U>

  template<class T2, class T1>
    constexpr T2& get(pair<T1, T2>& p) noexcept;
  template<class T2, class T1>
    constexpr const T2& get(const pair<T1, T2>& p) noexcept;
  template<class T2, class T1>
    constexpr T2&& get(pair<T1, T2>&& p) noexcept;
  template<class T2, class T1>
    constexpr const T2&& get(const pair<T1, T2>&& p) noexcept;

  // 22.3.5, pair piecewise construction
  struct piecewise_construct_t {
    explicit piecewise_construct_t() = default;
  };
  inline constexpr piecewise_construct_t piecewise_construct{};
  template<class... Types> class tuple;          // defined in <tuple> (22.4.2)

  // in-place construction
  struct in_place_t {
    explicit in_place_t() = default;
  };
  inline constexpr in_place_t in_place{};

  template<class T>
    struct in_place_type_t {
      explicit in_place_type_t() = default;
    };
  template<class T> constexpr in_place_type_t<T> in_place_type{};

  template<size_t I>
    struct in_place_index_t {
      explicit in_place_index_t() = default;
    };
  template<size_t I> constexpr in_place_index_t<I> in_place_index{};

  // 22.6.8, class monostate
  struct monostate;

  // 22.6.9, monostate relational operators
  constexpr bool operator==(monostate, monostate) noexcept;
  constexpr strong_ordering operator<=>(monostate, monostate) noexcept;

  // 22.6.12, hash support
  template<class T> struct hash;
  template<> struct hash<monostate>;
}
```

22.2.2 swap [utility.swap]

```
template<class T>
  constexpr void swap(T& a, T& b) noexcept(see below);
```

1 *Constraints*: `is_move_constructible_v<T>` is `true` and `is_move_assignable_v<T>` is `true`.

2 *Preconditions*: Type `T` meets the *Cpp17MoveConstructible* (Table 31) and *Cpp17MoveAssignable* (Table 33) requirements.

3 *Effects*: Exchanges values stored in two locations.

4 *Remarks*: The exception specification is equivalent to:

```
is_nothrow_move_constructible_v<T> && is_nothrow_move_assignable_v<T>
```

```
template<class T, size_t N>
  constexpr void swap(T (&a)[N], T (&b)[N]) noexcept(is_nothrow_swappable_v<T>);
```

5 *Constraints*: `is_swappable_v<T>` is `true`.

6 *Preconditions*: `a[i]` is swappable with (16.4.4.3) `b[i]` for all `i` in the range $[0, N)$.

7 *Effects*: As if by `swap_ranges(a, a + N, b)`.

22.2.3 `exchange` [utility.exchange]

```
template<class T, class U = T>
  constexpr T exchange(T& obj, U&& new_val) noexcept(see below);
```

1 *Effects*: Equivalent to:

```
T old_val = std::move(obj);
obj = std::forward<U>(new_val);
return old_val;
```

2 *Remarks*: The exception specification is equivalent to:

```
is_nothrow_move_constructible_v<T> && is_nothrow_assignable_v<T&, U>
```

22.2.4 Forward/move helpers [forward]

1 The library provides templated helper functions to simplify applying move semantics to an lvalue and to simplify the implementation of forwarding functions. All functions specified in this subclause are signal-safe (17.14.5).

```
template<class T> constexpr T&& forward(remove_reference_t<T>& t) noexcept;
template<class T> constexpr T&& forward(remove_reference_t<T>&& t) noexcept;
```

2 *Mandates*: For the second overload, `is_lvalue_reference_v<T>` is `false`.

3 *Returns*: `static_cast<T&&>(t)`.

4 [*Example 1*:

```
template<class T, class A1, class A2>
shared_ptr<T> factory(A1&& a1, A2&& a2) {
  return shared_ptr<T>(new T(std::forward<A1>(a1), std::forward<A2>(a2)));
}

struct A {
  A(int&, const double&);
};

void g() {
  shared_ptr<A> sp1 = factory<A>(2, 1.414); // error: 2 will not bind to int&
  int i = 2;
  shared_ptr<A> sp2 = factory<A>(i, 1.414); // OK
}
```

In the first call to `factory`, `A1` is deduced as `int`, so `2` is forwarded to `A`'s constructor as an rvalue. In the second call to `factory`, `A1` is deduced as `int&`, so `i` is forwarded to `A`'s constructor as an lvalue. In both cases, `A2` is deduced as `double`, so `1.414` is forwarded to `A`'s constructor as an rvalue. — *end example*]

```
template<class T, class U>
  constexpr auto forward_like(U&& x) noexcept -> see below;
```

5 *Mandates*: `T` is a referenceable type (3.46).

(5.1) — Let *COPY_CONST*`(A, B)` be `const B` if `A` is a const type, otherwise `B`.

(5.2) — Let *OVERRIDE_REF*`(A, B)` be `remove_reference_t<B>&&` if `A` is an rvalue reference type, otherwise `B&`.

(5.3) — Let `V` be

```
OVERRIDE_REF(T&&, COPY_CONST(remove_reference_t<T>, remove_reference_t<U>))
```

6 *Returns*: `static_cast<V>(x)`.

7 *Remarks*: The return type is `V`.

8 [*Example 2*:

```
struct accessor {
  vector<string>* container;
  decltype(auto) operator[](this auto&& self, size_t i) {
    return std::forward_like<decltype(self)>((*container)[i]);
  }
};
void g() {
  vector v{"a"s, "b"s};
  accessor a{&v};
  string& x = a[0];                               // OK, binds to lvalue reference
  string&& y = std::move(a)[0];                   // OK, is rvalue reference
  string const&& z = std::move(as_const(a))[1]; // OK, is const&&
  string& w = as_const(a)[1];                     // error: will not bind to non-const
}
```

— *end example*]

```
template<class T> constexpr remove_reference_t<T>&& move(T&& t) noexcept;
```

9 *Returns*: `static_cast<remove_reference_t<T>&&>(t)`.

10 [*Example 3*:

```
template<class T, class A1>
shared_ptr<T> factory(A1&& a1) {
  return shared_ptr<T>(new T(std::forward<A1>(a1)));
}

struct A {
  A();
  A(const A&);       // copies from lvalues
  A(A&&);            // moves from rvalues
};

void g() {
  A a;
  shared_ptr<A> sp1 = factory<A>(a);                // "a" binds to A(const A&)
  shared_ptr<A> sp2 = factory<A>(std::move(a));     // "a" binds to A(A&&)
}
```

In the first call to `factory`, `A1` is deduced as `A&`, so `a` is forwarded as a non-const lvalue. This binds to the constructor `A(const A&)`, which copies the value from `a`. In the second call to `factory`, because of the call `std::move(a)`, `A1` is deduced as `A`, so `a` is forwarded as an rvalue. This binds to the constructor `A(A&&)`, which moves the value from `a`. — *end example*]

```
template<class T> constexpr conditional_t<
    !is_nothrow_move_constructible_v<T> && is_copy_constructible_v<T>, const T&, T&&>
  move_if_noexcept(T& x) noexcept;
```

11 *Returns*: `std::move(x)`.

22.2.5 Function template `as_const` [utility.as.const]

```
template<class T> constexpr add_const_t<T>& as_const(T& t) noexcept;
```

1 *Returns*: `t`.

22.2.6 Function template `declval` [declval]

1 The library provides the function template `declval` to simplify the definition of expressions which occur as unevaluated operands (7.2.3).

```
template<class T> add_rvalue_reference_t<T> declval() noexcept;      // as unevaluated operand
```

2 *Mandates*: This function is not odr-used (6.3).

3 *Remarks*: The template parameter `T` of `declval` may be an incomplete type.

4 [*Example 1*:

```
template<class To, class From> decltype(static_cast<To>(declval<From>())) convert(From&&);
```

declares a function template `convert` which only participates in overload resolution if the type `From` can be explicitly converted to type `To`. For another example see class template `common_type` (21.3.8.7). — *end example*]

22.2.7 Integer comparison functions [utility.intcmp]

```
template<class T, class U>
  constexpr bool cmp_equal(T t, U u) noexcept;
```

1 *Mandates*: Each of `T` and `U` is a signed or unsigned integer type (6.9.2).

2 *Effects*: Equivalent to:

```
using UT = make_unsigned_t<T>;
using UU = make_unsigned_t<U>;
if constexpr (is_signed_v<T> == is_signed_v<U>)
  return t == u;
else if constexpr (is_signed_v<T>)
  return t < 0 ? false : UT(t) == u;
else
  return u < 0 ? false : t == UU(u);
```

```
template<class T, class U>
  constexpr bool cmp_not_equal(T t, U u) noexcept;
```

3 *Effects*: Equivalent to: `return !cmp_equal(t, u);`

```
template<class T, class U>
  constexpr bool cmp_less(T t, U u) noexcept;
```

4 *Mandates*: Each of `T` and `U` is a signed or unsigned integer type (6.9.2).

5 *Effects*: Equivalent to:

```
using UT = make_unsigned_t<T>;
using UU = make_unsigned_t<U>;
if constexpr (is_signed_v<T> == is_signed_v<U>)
  return t < u;
else if constexpr (is_signed_v<T>)
  return t < 0 ? true : UT(t) < u;
else
  return u < 0 ? false : t < UU(u);
```

```
template<class T, class U>
  constexpr bool cmp_greater(T t, U u) noexcept;
```

6 *Effects*: Equivalent to: `return cmp_less(u, t);`

```
template<class T, class U>
  constexpr bool cmp_less_equal(T t, U u) noexcept;
```

7 *Effects*: Equivalent to: `return !cmp_greater(t, u);`

```
template<class T, class U>
  constexpr bool cmp_greater_equal(T t, U u) noexcept;
```

8 *Effects*: Equivalent to: `return !cmp_less(t, u);`

```
template<class R, class T>
  constexpr bool in_range(T t) noexcept;
```

9 *Mandates*: Each of `T` and `R` is a signed or unsigned integer type (6.9.2).

10 *Effects*: Equivalent to:

```
    return cmp_greater_equal(t, numeric_limits<R>::min()) &&
           cmp_less_equal(t, numeric_limits<R>::max());
```

11 [*Note 1*: These function templates cannot be used to compare `byte`, `char`, `char8_t`, `char16_t`, `char32_t`, `wchar_t`, and `bool`. — *end note*]

22.2.8 Function template `to_underlying` [utility.underlying]

```
template<class T>
  constexpr underlying_type_t<T> to_underlying(T value) noexcept;
```

1 *Returns*: `static_cast<underlying_type_t<T>>(value)`.

22.2.9 Undefined behavior [utility.undefined]

```
[[noreturn]] void unreachable();
```

1 *Preconditions*: `false` is `true`.

[*Note 1*: This precondition cannot be satisfied, thus the behavior of calling `unreachable` is undefined. — *end note*]

2 [*Example 1*:

```
int f(int x) {
  switch (x) {
  case 0:
  case 1:
    return x;
  default:
    std::unreachable();
  }
}
int a = f(1);           // OK, a has value 1
int b = f(3);           // undefined behavior
```

— *end example*]

```
void observable_checkpoint() noexcept;
```

3 *Effects*: Establishes an observable checkpoint (4.1.2).

22.2.10 Class template `constant_wrapper` [const.wrap.class]

```
namespace std {
  template<class T>
  struct cw-fixed-value {                                          // exposition only

    template<constexpr-param T, constexpr-param R>
      constexpr auto operator>>=(this T, R) noexcept
        -> constant_wrapper<(T::value >>= R::value)> { return {}; }
  };

  template<cw-fixed-value X, class>
  struct constant_wrapper : cw-operators {
    static constexpr const auto & value = X.data;
    using type = constant_wrapper;
    using value_type = decltype(X)::type;

    template<constexpr-param R>
      constexpr auto operator=(R) const noexcept
        -> constant_wrapper<(value = R::value)> { return {}; }

    constexpr operator decltype(value)() const noexcept { return value; }

    template<class... Args>
      static constexpr decltype(auto) operator()(Args&&... args) noexcept(see below);
    template<class... Args>
      static constexpr decltype(auto) operator[](Args&&... args) noexcept(see below);
  };
}
```

1 The class template `constant_wrapper` aids in metaprogramming by ensuring that the evaluation of expressions comprised entirely of `constant_wrapper` are core constant expressions (7.7.2), regardless of the context in which they appear. In particular, this enables use of `constant_wrapper` values that are passed as arguments to constexpr functions to be used in constant expressions.

2 [*Note 1*: The unnamed second template parameter to `constant_wrapper` is present to aid argument-dependent lookup (6.5.4) in finding overloads for which `constant_wrapper`'s wrapped value is a suitable argument, but for which the `constant_wrapper` itself is not. — *end note*]

3 [*Example 1*:

```
constexpr auto initial_phase(auto quantity_1, auto quantity_2) {
  return quantity_1 + quantity_2;
}

constexpr auto middle_phase(auto tbd) {
  return tbd;
}

void final_phase(auto gathered, auto available) {
  if constexpr (gathered == available)
    std::cout << "Profit!\n";
}

void impeccable_underground_planning() {
  auto gathered_quantity = middle_phase(initial_phase(std::cw<42>, std::cw<13>));
  static_assert(gathered_quantity == 55);
  auto all_available = std::cw<55>;
  final_phase(gathered_quantity, all_available);
}

void deeply_flawed_underground_planning() {
  constexpr auto gathered_quantity = middle_phase(initial_phase(42, 13));
  constexpr auto all_available = 55;
  final_phase(gathered_quantity, all_available);  // error: gathered == available
                                                  // is not a constant expression
}
```

— *end example*]

```
constexpr cw-fixed-value(T (&arr)[Extent]) noexcept;
```

4 *Effects*: Initialize elements of *data* with corresponding elements of `arr`.

```
template<class... Args>
  static constexpr decltype(auto) operator()(Args&&... args) noexcept(see below);
```

5 Let *call-expr* be `constant_wrapper<`*INVOKE*`(value, remove_cvref_t<Args>::value...)>{}` if all types in `remove_cvref_t<Args>...` satisfy *constexpr-param* and `constant_wrapper<`*INVOKE*`(value, remove_cvref_t<Args>::value...)>` is a valid type, otherwise let *call-expr* be *INVOKE*`(value, std::forward<Args>(args)...)`.

6 *Constraints*: *call-expr* is a valid expression.

7 *Effects*: Equivalent to: `return` *call-expr*`;`

8 *Remarks*: The exception specification is equivalent to `noexcept(`*call-expr*`)`.

```
template<class... Args>
  static constexpr decltype(auto) operator[](Args&&... args) noexcept(see below);
```

9 Let *subscr-expr* be `constant_wrapper<value[remove_cvref_t<Args>::value...]>{}` if all types in `remove_cvref_t<Args>...` satisfy *constexpr-param* and `constant_wrapper<value[remove_cvref_t<Args>::value...]>` is a valid type, otherwise let *subscr-expr* be `value[std::forward<Args>(args)...]`.

10 *Constraints*: *subscr-expr* is a valid expression.

11 *Effects*: Equivalent to: `return` *subscr-expr*`;`

12 *Remarks*: The exception specification is equivalent to `noexcept(`*subscr-expr*`)`.

22.3 Pairs [pairs]

22.3.1 General [pairs.general]

1 The library provides a template for heterogeneous pairs of values. The library also provides a matching function template to simplify their construction and several templates that provide access to `pair` objects as if they were `tuple` objects (see 22.4.7 and 22.4.8).

22.3.2 Class template pair [pairs.pair]

```
namespace std {
  template<class T1, class T2>
  struct pair {
    using first_type  = T1;
    using second_type = T2;

    T1 first;
    T2 second;

    pair(const pair&) = default;
    pair(pair&&) = default;
    constexpr explicit(see below) pair();
    constexpr explicit(see below) pair(const T1& x, const T2& y);
    template<class U1 = T1, class U2 = T2>
      constexpr explicit(see below) pair(U1&& x, U2&& y);
    template<class U1, class U2>
      constexpr explicit(see below) pair(pair<U1, U2>& p);
    template<class U1, class U2>
      constexpr explicit(see below) pair(const pair<U1, U2>& p);
    template<class U1, class U2>
      constexpr explicit(see below) pair(pair<U1, U2>&& p);
    template<class U1, class U2>
      constexpr explicit(see below) pair(const pair<U1, U2>&& p);
    template<pair-like P>
      constexpr explicit(see below) pair(P&& p);
    template<class... Args1, class... Args2>
      constexpr pair(piecewise_construct_t,
                     tuple<Args1...> first_args, tuple<Args2...> second_args);
```

```
    constexpr pair& operator=(const pair& p);
    constexpr const pair& operator=(const pair& p) const;
    template<class U1, class U2>
      constexpr pair& operator=(const pair<U1, U2>& p);
    template<class U1, class U2>
      constexpr const pair& operator=(const pair<U1, U2>& p) const;
    constexpr pair& operator=(pair&& p) noexcept(see below);
    constexpr const pair& operator=(pair&& p) const;
    template<class U1, class U2>
      constexpr pair& operator=(pair<U1, U2>&& p);
    template<class U1, class U2>
      constexpr const pair& operator=(pair<U1, U2>&& p) const;
    template<pair-like P>
      constexpr pair& operator=(P&& p);
    template<pair-like P>
      constexpr const pair& operator=(P&& p) const;

    constexpr void swap(pair& p) noexcept(see below);
    constexpr void swap(const pair& p) const noexcept(see below);
  };

  template<class T1, class T2>
    pair(T1, T2) -> pair<T1, T2>;
}
```

1 Member functions of `pair` do not throw exceptions unless one of the element-wise operations specified to be called for that operation throws an exception.

2 The defaulted move and copy constructor, respectively, of `pair` is a constexpr function if and only if all required element-wise initializations for move and copy, respectively, would be constexpr-suitable (9.2.6).

3 If `(is_trivially_destructible_v<T1> && is_trivially_destructible_v<T2>)` is `true`, then the destructor of `pair` is trivial.

4 `pair<T, U>` is a structural type (13.2) if `T` and `U` are both structural types. Two values `p1` and `p2` of type `pair<T, U>` are template-argument-equivalent (13.6) if and only if `p1.first` and `p2.first` are template-argument-equivalent and `p1.second` and `p2.second` are template-argument-equivalent.

```
constexpr explicit(see below) pair();
```

5 *Constraints*:

(5.1) — `is_default_constructible_v<T1>` is `true` and

(5.2) — `is_default_constructible_v<T2>` is `true`.

6 *Effects*: Value-initializes `first` and `second`.

7 *Remarks*: The expression inside `explicit` evaluates to `true` if and only if either `T1` or `T2` is not implicitly default-constructible.

[*Note 1*: This behavior can be implemented with a trait that checks whether a `const T1&` or a `const T2&` can be initialized with `{}`. — *end note*]

```
constexpr explicit(see below) pair(const T1& x, const T2& y);
```

8 *Constraints*:

(8.1) — `is_copy_constructible_v<T1>` is `true` and

(8.2) — `is_copy_constructible_v<T2>` is `true`.

9 *Effects*: Initializes `first` with `x` and `second` with `y`.

10 *Remarks*: The expression inside `explicit` is equivalent to:

```
!is_convertible_v<const T1&, T1> || !is_convertible_v<const T2&, T2>
```

```
template<class U1 = T1, class U2 = T2> constexpr explicit(see below) pair(U1&& x, U2&& y);
```

11 *Constraints*:

(11.1) — `is_constructible_v<T1, U1>` is `true` and

(11.2) — `is_constructible_v<T2, U2>` is `true`.

12 *Effects*: Initializes `first` with `std::forward<U1>(x)` and `second` with `std::forward<U2>(y)`.

13 *Remarks*: The expression inside `explicit` is equivalent to:

```
!is_convertible_v<U1, T1> || !is_convertible_v<U2, T2>
```

This constructor is defined as deleted if `reference_constructs_from_temporary_v<first_type, U1&&>` is `true` or `reference_constructs_from_temporary_v<second_type, U2&&>` is `true`.

```
template<class U1, class U2> constexpr explicit(see below) pair(pair<U1, U2>& p);
template<class U1, class U2> constexpr explicit(see below) pair(const pair<U1, U2>& p);
template<class U1, class U2> constexpr explicit(see below) pair(pair<U1, U2>&& p);
template<class U1, class U2> constexpr explicit(see below) pair(const pair<U1, U2>&& p);
template<pair-like P> constexpr explicit(see below) pair(P&& p);
```

14 Let *FWD*(u) be `static_cast<decltype(u)>(u)`.

15 *Constraints*:

(15.1) — For the last overload, `remove_cvref_t<P>` is not a specialization of `ranges::subrange`,

(15.2) — `is_constructible_v<T1, decltype(get<0>(`*FWD*`(p)))>` is `true`, and

(15.3) — `is_constructible_v<T2, decltype(get<1>(`*FWD*`(p)))>` is `true`.

16 *Effects*: Initializes `first` with `get<0>(`*FWD*`(p))` and `second` with `get<1>(`*FWD*`(p))`.

17 *Remarks*: The expression inside `explicit` is equivalent to:

```
!is_convertible_v<decltype(get<0>(FWD(p))), T1> ||
!is_convertible_v<decltype(get<1>(FWD(p))), T2>
```

The constructor is defined as deleted if

```
reference_constructs_from_temporary_v<first_type, decltype(get<0>(FWD(p)))> ||
reference_constructs_from_temporary_v<second_type, decltype(get<1>(FWD(p)))>
```

is `true`.

```
template<class... Args1, class... Args2>
  constexpr pair(piecewise_construct_t,
                 tuple<Args1...> first_args, tuple<Args2...> second_args);
```

18 *Mandates*:

(18.1) — `is_constructible_v<T1, Args1...>` is `true` and

(18.2) — `is_constructible_v<T2, Args2...>` is `true`.

19 *Effects*: Initializes `first` with arguments of types `Args1...` obtained by forwarding the elements of `first_args` and initializes `second` with arguments of types `Args2...` obtained by forwarding the elements of `second_args`. (Here, forwarding an element `x` of type `U` within a `tuple` object means calling `std::forward<U>(x)`.) This form of construction, whereby constructor arguments for `first` and `second` are each provided in a separate `tuple` object, is called *piecewise construction*.

[*Note 2*: If a data member of `pair` is of reference type and its initialization binds it to a temporary object, the program is ill-formed (11.9.3). — *end note*]

```
constexpr pair& operator=(const pair& p);
```

20 *Effects*: Assigns `p.first` to `first` and `p.second` to `second`.

21 *Returns*: `*this`.

22 *Remarks*: This operator is defined as deleted unless `is_copy_assignable_v<T1>` is `true` and `is_copy_assignable_v<T2>` is `true`.

```
constexpr const pair& operator=(const pair& p) const;
```

23 *Constraints*:

(23.1) — `is_copy_assignable_v<const T1>` is `true` and

(23.2) — `is_copy_assignable_v<const T2>` is `true`.

24 *Effects*: Assigns `p.first` to `first` and `p.second` to `second`.

25 *Returns*: `*this`.

```
template<class U1, class U2> constexpr pair& operator=(const pair<U1, U2>& p);
```

26 *Constraints*:

(26.1) — `is_assignable_v<T1&, const U1&>` is `true` and

(26.2) — `is_assignable_v<T2&, const U2&>` is `true`.

27 *Effects*: Assigns `p.first` to `first` and `p.second` to `second`.

28 *Returns*: `*this`.

```
template<class U1, class U2> constexpr const pair& operator=(const pair<U1, U2>& p) const;
```

29 *Constraints*:

(29.1) — `is_assignable_v<const T1&, const U1&>` is `true`, and

(29.2) — `is_assignable_v<const T2&, const U2&>` is `true`.

30 *Effects*: Assigns `p.first` to `first` and `p.second` to `second`.

31 *Returns*: `*this`.

```
constexpr pair& operator=(pair&& p) noexcept(see below);
```

32 *Constraints*:

(32.1) — `is_move_assignable_v<T1>` is `true` and

(32.2) — `is_move_assignable_v<T2>` is `true`.

33 *Effects*: Assigns `std::forward<T1>(p.first)` to `first` and `std::forward<T2>(p.second)` to `second`.

34 *Returns*: `*this`.

35 *Remarks*: The exception specification is equivalent to:

```
is_nothrow_move_assignable_v<T1> && is_nothrow_move_assignable_v<T2>
```

```
constexpr const pair& operator=(pair&& p) const;
```

36 *Constraints*:

(36.1) — `is_assignable_v<const T1&, T1>` is `true` and

(36.2) — `is_assignable_v<const T2&, T2>` is `true`.

37 *Effects*: Assigns `std::forward<T1>(p.first)` to `first` and `std::forward<T2>(p.second)` to `second`.

38 *Returns*: `*this`.

```
template<class U1, class U2> constexpr pair& operator=(pair<U1, U2>&& p);
```

39 *Constraints*:

(39.1) — `is_assignable_v<T1&, U1>` is `true` and

(39.2) — `is_assignable_v<T2&, U2>` is `true`.

40 *Effects*: Assigns `std::forward<U1>(p.first) first` and `std::forward<U2>(p.second)` to `second`.

41 *Returns*: `*this`.

```
template<pair-like P> constexpr pair& operator=(P&& p);
```

42 *Constraints*:

(42.1) — *`different-from`*`<P, pair>` (25.5.2) is `true`,

(42.2) — `remove_cvref_t<P>` is not a specialization of `ranges::subrange`,

(42.3) — `is_assignable_v<T1&, decltype(get<0>(std::forward<P>(p)))>` is `true`, and

(42.4) — `is_assignable_v<T2&, decltype(get<1>(std::forward<P>(p)))>` is `true`.

43 *Effects*: Assigns `get<0>(std::forward<P>(p))` to `first` and `get<1>(std::forward<P>(p))` to `second`.

44 *Returns*: `*this`.

```
template<pair-like P> constexpr const pair& operator=(P&& p) const;
```

45 *Constraints*:

(45.1) — *different-from*`<P, pair>` (25.5.2) is `true`,

(45.2) — `remove_cvref_t<P>` is not a specialization of `ranges::subrange`,

(45.3) — `is_assignable_v<const T1&, decltype(get<0>(std::forward<P>(p)))>` is `true`, and

(45.4) — `is_assignable_v<const T2&, decltype(get<1>(std::forward<P>(p)))>` is `true`.

46 *Effects*: Assigns `get<0>(std::forward<P>(p))` to `first` and `get<1>(std::forward<P>(p))` to `second`.

47 *Returns*: `*this`.

```
template<class U1, class U2> constexpr const pair& operator=(pair<U1, U2>&& p) const;
```

48 *Constraints*:

(48.1) — `is_assignable_v<const T1&, U1>` is `true`, and

(48.2) — `is_assignable_v<const T2&, U2>` is `true`.

49 *Effects*: Assigns `std::forward<U1>(p.first)` to `first` and `std::forward<U2>(u.second)` to `second`.

50 *Returns*: `*this`.

```
constexpr void swap(pair& p) noexcept(see below);
constexpr void swap(const pair& p) const noexcept(see below);
```

51 *Mandates*:

(51.1) — For the first overload, `is_swappable_v<T1>` is `true` and `is_swappable_v<T2>` is `true`.

(51.2) — For the second overload, `is_swappable_v<const T1>` is `true` and `is_swappable_v<const T2>` is `true`.

52 *Preconditions*: `first` is swappable with (16.4.4.3) `p.first` and `second` is swappable with `p.second`.

53 *Effects*: Swaps `first` with `p.first` and `second` with `p.second`.

54 *Remarks*: The exception specification is equivalent to:

(54.1) — `is_nothrow_swappable_v<T1> && is_nothrow_swappable_v<T2>` for the first overload, and

(54.2) — `is_nothrow_swappable_v<const T1> && is_nothrow_swappable_v<const T2>` for the second overload.

22.3.3 Specialized algorithms [pairs.spec]

```
template<class T1, class T2, class U1, class U2>
  constexpr bool operator==(const pair<T1, T2>& x, const pair<U1, U2>& y);
```

1 *Constraints*: `x.first == y.first` and `x.second == y.second` are valid expressions and each of `decltype(x.first == y.first)` and `decltype(x.second == y.second)` models *boolean-testable*.

2 *Returns*: `x.first == y.first && x.second == y.second`.

```
template<class T1, class T2, class U1, class U2>
  constexpr common_comparison_category_t<synth-three-way-result<T1, U1>,
                                         synth-three-way-result<T2, U2>>
    operator<=>(const pair<T1, T2>& x, const pair<U1, U2>& y);
```

3 *Effects*: Equivalent to:

```
if (auto c = synth-three-way(x.first, y.first); c != 0) return c;
return synth-three-way(x.second, y.second);
```

```
template<class T1, class T2>
  constexpr void swap(pair<T1, T2>& x, pair<T1, T2>& y) noexcept(noexcept(x.swap(y)));
```

```
template<class T1, class T2>
  constexpr void swap(const pair<T1, T2>& x, const pair<T1, T2>& y) noexcept(noexcept(x.swap(y)));
```

4 *Constraints*:

(4.1) — For the first overload, `is_swappable_v<T1>` is `true` and `is_swappable_v<T2>` is `true`.

(4.2) — For the second overload, `is_swappable_v<const T1>` is `true` and `is_swappable_v<const T2>` is `true`.

5 *Effects*: Equivalent to `x.swap(y)`.

```
template<class T1, class T2>
  constexpr pair<unwrap_ref_decay_t<T1>, unwrap_ref_decay_t<T2>> make_pair(T1&& x, T2&& y);
```

6 *Returns*:

```
pair<unwrap_ref_decay_t<T1>,
     unwrap_ref_decay_t<T2>>(std::forward<T1>(x), std::forward<T2>(y))
```

7 [*Example 1*: In place of:

```
return pair<int, double>(5, 3.1415926);      // explicit types
```

a C++ program may contain:

```
return make_pair(5, 3.1415926);              // types are deduced
```

— *end example*]

22.3.4 Tuple-like access to pair [pair.astuple]

```
template<class T1, class T2>
  struct tuple_size<pair<T1, T2>> : integral_constant<size_t, 2> { };

template<size_t I, class T1, class T2>
  struct tuple_element<I, pair<T1, T2>> {
    using type = see below ;
  };
```

1 *Mandates*: `I` < 2.

2 *Result*: The type `T1` if `I` is 0, otherwise the type `T2`.

```
template<size_t I, class T1, class T2>
  constexpr tuple_element_t<I, pair<T1, T2>>& get(pair<T1, T2>& p) noexcept;
template<size_t I, class T1, class T2>
  constexpr const tuple_element_t<I, pair<T1, T2>>& get(const pair<T1, T2>& p) noexcept;
template<size_t I, class T1, class T2>
  constexpr tuple_element_t<I, pair<T1, T2>>&& get(pair<T1, T2>&& p) noexcept;
template<size_t I, class T1, class T2>
  constexpr const tuple_element_t<I, pair<T1, T2>>&& get(const pair<T1, T2>&& p) noexcept;
```

3 *Mandates*: `I` < 2.

4 *Returns*:

(4.1) — If `I` is 0, returns a reference to `p.first`.

(4.2) — If `I` is 1, returns a reference to `p.second`.

```
template<class T1, class T2>
  constexpr T1& get(pair<T1, T2>& p) noexcept;
template<class T1, class T2>
  constexpr const T1& get(const pair<T1, T2>& p) noexcept;
template<class T1, class T2>
  constexpr T1&& get(pair<T1, T2>&& p) noexcept;
template<class T1, class T2>
  constexpr const T1&& get(const pair<T1, T2>&& p) noexcept;
```

5 *Mandates*: `T1` and `T2` are distinct types.

6 *Returns*: A reference to `p.first`.

```
template<class T2, class T1>
  constexpr T2& get(pair<T1, T2>& p) noexcept;
template<class T2, class T1>
  constexpr const T2& get(const pair<T1, T2>& p) noexcept;
template<class T2, class T1>
  constexpr T2&& get(pair<T1, T2>&& p) noexcept;
template<class T2, class T1>
  constexpr const T2&& get(const pair<T1, T2>&& p) noexcept;
```

7 *Mandates*: `T1` and `T2` are distinct types.

8 *Returns*: A reference to `p.second`.

22.3.5 Piecewise construction [pair.piecewise]

```
struct piecewise_construct_t {
  explicit piecewise_construct_t() = default;
};
inline constexpr piecewise_construct_t piecewise_construct{};
```

1 The `struct piecewise_construct_t` is an empty class type used as a unique type to disambiguate constructor and function overloading. Specifically, `pair` has a constructor with `piecewise_construct_t` as the first argument, immediately followed by two `tuple` (22.4) arguments used for piecewise construction of the elements of the `pair` object.

22.4 Tuples [tuple]

22.4.1 General [tuple.general]

1 Subclause 22.4 describes the tuple library that provides a tuple type as the class template `tuple` that can be instantiated with any number of arguments. Each template argument specifies the type of an element in the `tuple`. Consequently, tuples are heterogeneous, fixed-size collections of values. A specialization of `tuple` with two arguments behaves similarly to a specialization of `pair` with the same two arguments. See 22.3.

2 In addition to being available via inclusion of the `<tuple>` header, `ignore` (22.4.2) is available when `<utility>` (22.2) is included.

22.4.2 Header <tuple> synopsis [tuple.syn]

```
// all freestanding
#include <compare>              // see 17.12.1

namespace std {
  // 22.4.4, class template tuple
  template<class... Types>
    class tuple;

  // 22.4.3, concept tuple-like
  template<class T>
    concept tuple-like = see below;          // exposition only
  template<class T>
    concept pair-like =                      // exposition only
      tuple-like<T> && tuple_size_v<remove_cvref_t<T>> == 2;

  // 22.4.10, common_reference related specializations
  template<tuple-like TTuple, tuple-like UTuple,
           template<class> class TQual, template<class> class UQual>
    struct basic_common_reference<TTuple, UTuple, TQual, UQual>;
  template<tuple-like TTuple, tuple-like UTuple>
    struct common_type<TTuple, UTuple>;

  // ignore
  struct ignore-type {                       // exposition only
    constexpr const ignore-type&
      operator=(const auto &) const noexcept { return *this; }
  };
  inline constexpr ignore-type ignore;
```

```
// 22.4.5, tuple creation functions
template<class... TTypes>
  constexpr tuple<unwrap_ref_decay_t<TTypes>...> make_tuple(TTypes&&...);

  // 22.4.7, tuple helper classes
  template<class T>
    constexpr size_t tuple_size_v = tuple_size<T>::value;
}
```

22.4.3 Concept *tuple-like* [tuple.like]

```
template<class T>
  concept tuple-like = see below;            // exposition only
```

1 A type T models and satisfies the exposition-only concept *tuple-like* if remove_cvref_t<T> is a specialization of array, complex, pair, tuple, or ranges::subrange.

22.4.4 Class template tuple [tuple.tuple]

22.4.4.1 General [tuple.tuple.general]

```
namespace std {
  template<class... Types>
  class tuple {
  public:
    // 22.4.4.2, tuple construction
    constexpr explicit(see below) tuple();
    constexpr explicit(see below) tuple(const Types&...)          // only if sizeof...(Types) >= 1
      noexcept(see below);
    template<class... UTypes>
      constexpr explicit(see below) tuple(UTypes&&...)            // only if sizeof...(Types) >= 1
        noexcept(see below);

    tuple(const tuple&) = default;
    tuple(tuple&&) = default;

    template<class... UTypes>
      constexpr explicit(see below) tuple(tuple<UTypes...>&);
    template<class... UTypes>
      constexpr explicit(see below) tuple(const tuple<UTypes...>&);
    template<class... UTypes>

    template<tuple-like UTuple>
      constexpr tuple& operator=(UTuple&&);
    template<tuple-like UTuple>
      constexpr const tuple& operator=(UTuple&&) const;

    // 22.4.4.4, tuple swap
    constexpr void swap(tuple&) noexcept(see below);
    constexpr void swap(const tuple&) const noexcept(see below);
  };

  template<class... UTypes>
    tuple(UTypes...) -> tuple<UTypes...>;
  template<class T1, class T2>
    tuple(pair<T1, T2>) -> tuple<T1, T2>;
  template<class Alloc, class... UTypes>
    tuple(allocator_arg_t, Alloc, UTypes...) -> tuple<UTypes...>;
  template<class Alloc, class T1, class T2>
    tuple(allocator_arg_t, Alloc, pair<T1, T2>) -> tuple<T1, T2>;
  template<class Alloc, class... UTypes>
    tuple(allocator_arg_t, Alloc, tuple<UTypes...>) -> tuple<UTypes...>;
}
```

1 If a program declares an explicit or partial specialization of `tuple`, the program is ill-formed, no diagnostic required.

22.4.4.2 Construction [tuple.cnstr]

1 In the descriptions that follow, let i be in the range $[0, \texttt{sizeof...(Types)})$ in order, $\texttt{T}_i$ be the i^{th} type in `Types`, and $\texttt{U}_i$ be the i^{th} type in a template parameter pack named `UTypes`, where indexing is zero-based.

2 For each `tuple` constructor, an exception is thrown only if the construction of one of the types in `Types` throws an exception.

3 The defaulted move and copy constructor, respectively, of `tuple` is a constexpr function if and only if all required element-wise initializations for move and copy, respectively, would be constexpr-suitable (9.2.6). The defaulted move and copy constructor of `tuple<>` are constexpr functions.

4 If `is_trivially_destructible_v<`$\texttt{T}_i$`>` is `true` for all $\texttt{T}_i$, then the destructor of `tuple` is trivial.

5 The default constructor of `tuple<>` is trivial.

```
constexpr explicit(see below) tuple();
```

6 *Constraints*: `is_default_constructible_v<`$\texttt{T}_i$`>` is `true` for all i.

7 *Effects*: Value-initializes each element.

8 *Remarks*: The expression inside `explicit` evaluates to `true` if and only if $\texttt{T}_i$ is not copy-list-initializable from an empty list for at least one i.

[*Note 1*: This behavior can be implemented with a trait that checks whether a `const` $\texttt{T}_i$`&` can be initialized with `{}`. — *end note*]

```
constexpr explicit(see below) tuple(const Types&...)
  noexcept((is_nothrow_copy_constructible_v<Types> && ...));
```

9 *Constraints*: `sizeof...(Types)` ≥ 1 and `is_copy_constructible_v<`$\texttt{T}_i$`>` is `true` for all i.

10 *Effects*: Initializes each element with the value of the corresponding parameter.

11 *Remarks*: The expression inside `explicit` is equivalent to:

```
!conjunction_v<is_convertible<const Types&, Types>...>
```

```
template<class... UTypes> constexpr explicit(see below) tuple(UTypes&&... u)
  noexcept((is_nothrow_constructible_v<Types, UTypes> && ...));
```

12 Let *disambiguating-constraint* be:

(12.1) — `negation<is_same<remove_cvref_t<`$\texttt{U}_0$`>, tuple>>` if `sizeof...(Types)` is 1;

(12.2) — otherwise, `bool_constant<!is_same_v<remove_cvref_t<`U_0`>, allocator_arg_t> || is_same_v<remove_cvref_t<`T_0`>, allocator_arg_t>>` if `sizeof...(Types)` is 2 or 3;

(12.3) — otherwise, `true_type`.

13 *Constraints*:

(13.1) — `sizeof...(Types)` equals `sizeof...(UTypes)`,

(13.2) — `sizeof...(Types)` ≥ 1, and

(13.3) — `conjunction_v<`*disambiguating-constraint*`, is_constructible<Types, UTypes>...>` is `true`.

14 *Effects*: Initializes the elements in the tuple with the corresponding value in `std::forward<UTypes>(u)`.

15 *Remarks*: The expression inside `explicit` is equivalent to:

```
!conjunction_v<is_convertible<UTypes, Types>...>
```

This constructor is defined as deleted if

```
(reference_constructs_from_temporary_v<Types, UTypes&&> || ...)
```

is `true`.

```
tuple(const tuple& u) = default;
```

16 *Mandates*: `is_copy_constructible_v<`T_i`>` is `true` for all i.

17 *Effects*: Initializes each element of `*this` with the corresponding element of `u`.

```
tuple(tuple&& u) = default;
```

18 *Constraints*: `is_move_constructible_v<`T_i`>` is `true` for all i.

19 *Effects*: For all i, initializes the i^{th} element of `*this` with `std::forward<`T_i`>(get<`i`>(u))`.

```
template<class... UTypes> constexpr explicit(see below) tuple(tuple<UTypes...>& u);
template<class... UTypes> constexpr explicit(see below) tuple(const tuple<UTypes...>& u);
template<class... UTypes> constexpr explicit(see below) tuple(tuple<UTypes...>&& u);
template<class... UTypes> constexpr explicit(see below) tuple(const tuple<UTypes...>&& u);
```

20 Let `I` be the pack `0, 1, ..., (sizeof...(Types) - 1)`.
Let *FWD*`(u)` be `static_cast<decltype(u)>(u)`.

21 *Constraints*:

(21.1) — `sizeof...(Types)` equals `sizeof...(UTypes)`, and

(21.2) — `(is_constructible_v<Types, decltype(get<I>(`*FWD*`(u)))> && ...)` is `true`, and

(21.3) — either `sizeof...(Types)` is not 1, or (when `Types...` expands to `T` and `UTypes...` expands to `U`) `is_convertible_v<decltype(u), T>`, `is_constructible_v<T, decltype(u)>`, and `is_same_v<T, U>` are all `false`.

22 *Effects*: For all i, initializes the i^{th} element of `*this` with `get<`i`>(`*FWD*`(u))`.

23 *Remarks*: The expression inside `explicit` is equivalent to:

```
!(is_convertible_v<decltype(get<I>(FWD(u))), Types> && ...)
```

The constructor is defined as deleted if

```
(reference_constructs_from_temporary_v<Types, decltype(get<I>(FWD(u)))> || ...)
```

is `true`.

```
template<class U1, class U2> constexpr explicit(see below) tuple(pair<U1, U2>& u);
template<class U1, class U2> constexpr explicit(see below) tuple(const pair<U1, U2>& u);
template<class U1, class U2> constexpr explicit(see below) tuple(pair<U1, U2>&& u);
template<class U1, class U2> constexpr explicit(see below) tuple(const pair<U1, U2>&& u);
```

24 Let *FWD*`(u)` be `static_cast<decltype(u)>(u)`.

25 *Constraints*:

(25.1) — `sizeof...(Types)` is 2,

(25.2) — `is_constructible_v<`T_0`, decltype(get<0>(`*FWD*`(u)))>` is `true`, and

(25.3) — `is_constructible_v<`T_1`, decltype(get<1>(`*FWD*`(u)))>` is `true`.

26 *Effects*: Initializes the first element with `get<0>(`*FWD*`(u))` and the second element with `get<1>(`*FWD*`(u))`.

27 *Remarks*: The expression inside `explicit` is equivalent to:

```
!is_convertible_v<decltype(get<0>(FWD(u))), T0> ||
!is_convertible_v<decltype(get<1>(FWD(u))), T1>
```

The constructor is defined as deleted if

```
reference_constructs_from_temporary_v<T0, decltype(get<0>(FWD(u)))> ||
reference_constructs_from_temporary_v<T1, decltype(get<1>(FWD(u)))>
```

is `true`.

```
template<tuple-like UTuple>
  constexpr explicit(see below) tuple(UTuple&& u);
```

28 Let `I` be the pack `0, 1, ..., (sizeof...(Types) - 1)`.

29 *Constraints*:

(29.1) — *different-from*`<UTuple, tuple>` (25.5.2) is `true`,

(29.2) — `remove_cvref_t<UTuple>` is not a specialization of `ranges::subrange`,

(29.3) — `sizeof...(Types)` equals `tuple_size_v<remove_cvref_t<UTuple>>`,

(29.4) — `(is_constructible_v<Types, decltype(get<I>(std::forward<UTuple>(u)))> && ...)` is `true`, and

(29.5) — either `sizeof...(Types)` is not 1, or (when `Types...` expands to `T`) `is_convertible_v<UTuple, T>` and `is_constructible_v<T, UTuple>` are both `false`.

30 *Effects*: For all i, initializes the i^{th} element of `*this` with `get<`i`>(std::forward<UTuple>(u))`.

31 *Remarks*: The expression inside `explicit` is equivalent to:

```
!(is_convertible_v<decltype(get<I>(std::forward<UTuple>(u))), Types> && ...)
```

The constructor is defined as deleted if

```
(reference_constructs_from_temporary_v<Types, decltype(get<I>(std::forward<UTuple>(u)))>
 || ...)
```

is `true`.

```
template<class Alloc>
  constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a);
template<class Alloc>
  constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, const Types&...);
template<class Alloc, class... UTypes>
  constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, UTypes&&...);
template<class Alloc>
  constexpr tuple(allocator_arg_t, const Alloc& a, const tuple&);
template<class Alloc>
  constexpr tuple(allocator_arg_t, const Alloc& a, tuple&&);
template<class Alloc, class... UTypes>
  constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, tuple<UTypes...>&);
template<class Alloc, class... UTypes>
  constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, const tuple<UTypes...>&);
template<class Alloc, class... UTypes>
  constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, tuple<UTypes...>&&);
template<class Alloc, class... UTypes>
  constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, const tuple<UTypes...>&&);
```

```
template<class Alloc, class U1, class U2>
  constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, pair<U1, U2>&);
template<class Alloc, class U1, class U2>
  constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, const pair<U1, U2>&);
template<class Alloc, class U1, class U2>
  constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, pair<U1, U2>&&);
template<class Alloc, class U1, class U2>
  constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, const pair<U1, U2>&&);
template<class Alloc, tuple-like UTuple>
  constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc& a, UTuple&&);
```

32 *Preconditions*: `Alloc` meets the *Cpp17Allocator* requirements (16.4.4.6.1).

33 *Effects*: Equivalent to the preceding constructors except that each element is constructed with uses-allocator construction (20.2.8.2).

22.4.4.3 Assignment [tuple.assign]

1 For each `tuple` assignment operator, an exception is thrown only if the assignment of one of the types in `Types` throws an exception. In the function descriptions that follow, let i be in the range $[0, \texttt{sizeof...(Types)})$ in order, $\texttt{T}_i$ be the i^{th} type in `Types`, and $\texttt{U}_i$ be the i^{th} type in a template parameter pack named `UTypes`, where indexing is zero-based.

```
constexpr tuple& operator=(const tuple& u);
```

2 *Effects*: Assigns each element of `u` to the corresponding element of `*this`.

3 *Returns*: `*this`.

4 *Remarks*: This operator is defined as deleted unless `is_copy_assignable_v<`$\texttt{T}_i$`>` is `true` for all i.

```
constexpr const tuple& operator=(const tuple& u) const;
```

5 *Constraints*: `(is_copy_assignable_v<const Types> && ...)` is `true`.

6 *Effects*: Assigns each element of `u` to the corresponding element of `*this`.

7 *Returns*: `*this`.

```
constexpr tuple& operator=(tuple&& u) noexcept(see below);
```

8 *Constraints*: `is_move_assignable_v<`$\texttt{T}_i$`>` is `true` for all i.

9 *Effects*: For all i, assigns `std::forward<`$\texttt{T}_i$`>(get<`i`>(u))` to `get<`i`>(*this)`.

10 *Returns*: `*this`.

11 *Remarks*: The exception specification is equivalent to the logical AND of the following expressions:

`is_nothrow_move_assignable_v<`$\texttt{T}_i$`>`

where $\texttt{T}_i$ is the i^{th} type in `Types`.

```
constexpr const tuple& operator=(tuple&& u) const;
```

12 *Constraints*: `(is_assignable_v<const Types&, Types> && ...)` is `true`.

13 *Effects*: For all i, assigns `std::forward<`$\texttt{T}_i$`>(get<`i`>(u))` to `get<`i`>(*this)`.

14 *Returns*: `*this`.

```
template<class... UTypes> constexpr tuple& operator=(const tuple<UTypes...>& u);
```

15 *Constraints*:

(15.1) — `sizeof...(Types)` equals `sizeof...(UTypes)` and

(15.2) — `is_assignable_v<`$\texttt{T}_i$`&, const` $\texttt{U}_i$`&>` is `true` for all i.

16 *Effects*: Assigns each element of `u` to the corresponding element of `*this`.

17 *Returns*: `*this`.

`template<class... UTypes> constexpr const tuple& operator=(const tuple<UTypes...>& u) const;`

18 *Constraints*:

(18.1) — `sizeof...(Types)` equals `sizeof...(UTypes)` and

(18.2) — `(is_assignable_v<const Types&, const UTypes&> && ...)` is `true`.

19 *Effects*: Assigns each element of `u` to the corresponding element of `*this`.

20 *Returns*: `*this`.

`template<class... UTypes> constexpr tuple& operator=(tuple<UTypes...>&& u);`

21 *Constraints*:

(21.1) — `sizeof...(Types)` equals `sizeof...(UTypes)` and

(21.2) — `is_assignable_v<`T_i`&, `U_i`>` is `true` for all i.

22 *Effects*: For all i, assigns `std::forward<`U_i`>(get<`i`>(u))` to `get<`i`>(*this)`.

23 *Returns*: `*this`.

`template<class... UTypes> constexpr const tuple& operator=(tuple<UTypes...>&& u) const;`

24 *Constraints*:

(24.1) — `sizeof...(Types)` equals `sizeof...(UTypes)` and

(24.2) — `(is_assignable_v<const Types&, UTypes> && ...)` is `true`.

25 *Effects*: For all i, assigns `std::forward<`U_i`>(get<`i`>(u))` to `get<`i`>(*this)`.

26 *Returns*: `*this`.

`template<class U1, class U2> constexpr tuple& operator=(const pair<U1, U2>& u);`

27 *Constraints*:

(27.1) — `sizeof...(Types)` is 2 and

(27.2) — `is_assignable_v<`T_0`&, const U1&>` is `true`, and

(27.3) — `is_assignable_v<`T_1`&, const U2&>` is `true`.

28 *Effects*: Assigns `u.first` to the first element of `*this` and `u.second` to the second element of `*this`.

29 *Returns*: `*this`.

`template<class U1, class U2> constexpr const tuple& operator=(const pair<U1, U2>& u) const;`

30 *Constraints*:

(30.1) — `sizeof...(Types)` is 2,

(30.2) — `is_assignable_v<const `T_0`&, const U1&>` is `true`, and

(30.3) — `is_assignable_v<const `T_1`&, const U2&>` is `true`.

31 *Effects*: Assigns `u.first` to the first element and `u.second` to the second element.

32 *Returns*: `*this`.

`template<class U1, class U2> constexpr tuple& operator=(pair<U1, U2>&& u);`

33 *Constraints*:

(33.1) — `sizeof...(Types)` is 2 and

(33.2) — `is_assignable_v<`T_0`&, U1>` is `true`, and

(33.3) — `is_assignable_v<`T_1`&, U2>` is `true`.

34 *Effects*: Assigns `std::forward<U1>(u.first)` to the first element of `*this` and `std::forward<U2>(u.second)` to the second element of `*this`.

35 *Returns*: `*this`.

`template<class U1, class U2> constexpr const tuple& operator=(pair<U1, U2>&& u) const;`

36 *Constraints*:

(36.1) — `sizeof...(Types)` is 2,

(36.2) — `is_assignable_v<const T0&, U1>` is `true`, and

(36.3) — `is_assignable_v<const T1&, U2>` is `true`.

37 *Effects*: Assigns `std::forward<U1>(u.first)` to the first element and `std::forward<U2>(u.second)` to the second element.

38 *Returns*: `*this`.

```
template<tuple-like UTuple>
  constexpr tuple& operator=(UTuple&& u);
```

39 *Constraints*:

(39.1) — *different-from*`<UTuple, tuple>` (25.5.2) is `true`,

(39.2) — `remove_cvref_t<UTuple>` is not a specialization of `ranges::subrange`,

(39.3) — `sizeof...(Types)` equals `tuple_size_v<remove_cvref_t<UTuple>>`, and

(39.4) — `is_assignable_v<Ti&, decltype(get<i>(std::forward<UTuple>(u)))>` is `true` for all i.

40 *Effects*: For all i, assigns `get<i>(std::forward<UTuple>(u))` to `get<i>(*this)`.

41 *Returns*: `*this`.

```
template<tuple-like UTuple>
  constexpr const tuple& operator=(UTuple&& u) const;
```

42 *Constraints*:

(42.1) — *different-from*`<UTuple, tuple>` (25.5.2) is `true`,

(42.2) — `remove_cvref_t<UTuple>` is not a specialization of `ranges::subrange`,

(42.3) — `sizeof...(Types)` equals `tuple_size_v<remove_cvref_t<UTuple>>`, and

(42.4) — `is_assignable_v<const Ti&, decltype(get<i>(std::forward<UTuple>(u)))>` is `true` for all i.

43 *Effects*: For all i, assigns `get<i>(std::forward<UTuple>(u))` to `get<i>(*this)`.

44 *Returns*: `*this`.

22.4.4.4 `swap` [tuple.swap]

```
constexpr void swap(tuple& rhs) noexcept(see below);
constexpr void swap(const tuple& rhs) const noexcept(see below);
```

1 Let i be in the range $[0, $`sizeof...(Types)`$)$ in order.

2 *Mandates*:

(2.1) — For the first overload, `(is_swappable_v<Types> && ...)` is `true`.

(2.2) — For the second overload, `(is_swappable_v<const Types> && ...)` is `true`.

3 *Preconditions*: For all i, `get<i>(*this)` is swappable with (16.4.4.3) `get<i>(rhs)`.

4 *Effects*: For each i, calls `swap` for `get<i>(*this)` and `get<i>(rhs)`.

5 *Throws*: Nothing unless one of the element-wise `swap` calls throws an exception.

6 *Remarks*: The exception specification is equivalent to

(6.1) — `(is_nothrow_swappable_v<Types> && ...)` for the first overload and

(6.2) — `(is_nothrow_swappable_v<const Types> && ...)` for the second overload.

22.4.5 Tuple creation functions [tuple.creation]

```
template<class... TTypes>
  constexpr tuple<unwrap_ref_decay_t<TTypes>...> make_tuple(TTypes&&... t);
```

1 *Returns*: `tuple<unwrap_ref_decay_t<TTypes>...>(std::forward<TTypes>(t)...)`.

2 [*Example 1*:

```
int i; float j;
make_tuple(1, ref(i), cref(j));
```

creates a tuple of type `tuple<int, int&, const float&>`. — *end example*]

```
template<class... TTypes>
  constexpr tuple<TTypes&&...> forward_as_tuple(TTypes&&... t) noexcept;
```

3 *Effects*: Constructs a tuple of references to the arguments in `t` suitable for forwarding as arguments to a function. Because the result may contain references to temporary objects, a program shall ensure that the return value of this function does not outlive any of its arguments (e.g., the program should typically not store the result in a named variable).

4 *Returns*: `tuple<TTypes&&...>(std::forward<TTypes>(t)...)`.

```
template<class... TTypes>
  constexpr tuple<TTypes&...> tie(TTypes&... t) noexcept;
```

5 *Returns*: `tuple<TTypes&...>(t...)`.

6 [*Example 2*: `tie` functions allow one to create tuples that unpack tuples into variables. `ignore` can be used for elements that are not needed:

```
int i; std::string s;
tie(i, ignore, s) = make_tuple(42, 3.14, "C++");
// i == 42, s == "C++"
```

— *end example*]

```
template<tuple-like... Tuples>
  constexpr tuple<CTypes...> tuple_cat(Tuples&&... tpls);
```

7 Let n be `sizeof...(Tuples)`. For every integer $0 \le i < n$:

(7.1) — Let $\texttt{T}_i$ be the i^{th} type in `Tuples`.

(7.2) — Let $\texttt{U}_i$ be `remove_cvref_t<`$\texttt{T}_i$`>`.

(7.3) — Let $\texttt{tp}_i$ be the i^{th} element in the function parameter pack `tpls`.

(7.4) — Let S_i be `tuple_size_v<`$\texttt{U}_i$`>`.

(7.5) — Let E_i^k be `tuple_element_t<`k`, `$\texttt{U}_i$`>`.

(7.6) — Let e_i^k be `get<`k`>(std::forward<`$\texttt{T}_i$`>(`$\texttt{tp}_i$`))`.

(7.7) — Let $Elems_i$ be a pack of the types $E_i^0, \ldots, E_i^{S_i-1}$.

(7.8) — Let $elems_i$ be a pack of the expressions $e_i^0, \ldots, e_i^{S_i-1}$.

The types in `CTypes` are equal to the ordered sequence of the expanded packs of types $Elems_0\ldots$, $Elems_1\ldots$, …, $Elems_{n-1}\ldots$. Let `celems` be the ordered sequence of the expanded packs of expressions $elems_0\ldots$, …, $elems_{n-1}\ldots$.

8 *Mandates*: `(is_constructible_v<CTypes, decltype(celems)> && ...)` is `true`.

9 *Returns*: `tuple<CTypes...>(celems...)`.

22.4.6 Calling a function with a `tuple` of arguments [tuple.apply]

```
template<class F, tuple-like Tuple>
  constexpr apply_result_t<F, Tuple> apply(F&& f, Tuple&& t)
    noexcept(is_nothrow_applicable_v<F, Tuple>);
```

1 *Effects*: Given the exposition-only function template:

```
namespace std {
  template<class F, tuple-like Tuple, size_t... I>
  constexpr decltype(auto) apply-impl(F&& f, Tuple&& t, index_sequence<I...>) {
                                                                  // exposition only
    return INVOKE(std::forward<F>(f), get<I>(std::forward<Tuple>(t))...);   // see 22.10.4
  }
}
```

Equivalent to:

```
return apply-impl(std::forward<F>(f), std::forward<Tuple>(t),
                  make_index_sequence<tuple_size_v<remove_reference_t<Tuple>>>{});
```

```
template<class T, tuple-like Tuple>
  constexpr T make_from_tuple(Tuple&& t);
```

2 *Mandates*: If `tuple_size_v<remove_reference_t<Tuple>>` is 1, then `reference_constructs_from_temporary_v<T, decltype(get<0>(declval<Tuple>()))>` is `false`.

3 *Effects*: Given the exposition-only function template:

```
namespace std {
  template<class T, tuple-like Tuple, size_t... I>
    requires is_constructible_v<T, decltype(get<I>(declval<Tuple>()))...>
  constexpr T make-from-tuple-impl(Tuple&& t, index_sequence<I...>) {   // exposition only
    return T(get<I>(std::forward<Tuple>(t))...);
  }
}
```

Equivalent to:

```
return make-from-tuple-impl<T>(
           std::forward<Tuple>(t),
           make_index_sequence<tuple_size_v<remove_reference_t<Tuple>>>{});
```

[*Note 1*: The type of `T` must be supplied as an explicit template parameter, as it cannot be deduced from the argument list. — *end note*]

22.4.7 Tuple helper classes [tuple.helper]

```
template<class T> struct tuple_size;
```

1 Except where specified otherwise, all specializations of `tuple_size` meet the *Cpp17UnaryTypeTrait* requirements (21.3.2) with a base characteristic of `integral_constant<size_t, N>` for some `N`.

```
template<class... Types>
  struct tuple_size<tuple<Types...>> : integral_constant<size_t, sizeof...(Types)> { };

template<size_t I, class... Types>
  struct tuple_element<I, tuple<Types...>> {
    using type = TI;
  };
```

2 *Mandates*: `I` $<$ `sizeof...(Types)`.

3 *Result*: `TI` is the type of the `I`$^{\text{th}}$ element of `Types`, where indexing is zero-based.

```
template<class T> struct tuple_size<const T>;
```

4 Let `TS` denote `tuple_size<T>` of the cv-unqualified type `T`. If the expression `TS::value` is well-formed when treated as an unevaluated operand (7.2.3), then each specialization of the template meets the *Cpp17UnaryTypeTrait* requirements (21.3.2) with a base characteristic of

```
integral_constant<size_t, TS::value>
```

Otherwise, it has no member `value`.

5 Access checking is performed as if in a context unrelated to `TS` and `T`. Only the validity of the immediate context of the expression is considered.

[*Note 1*: The compilation of the expression can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the "immediate context" and can result in the program being ill-formed. — *end note*]

6 In addition to being available via inclusion of the `<tuple>` header, the template is available when any of the headers `<array>` (23.3.2), `<complex>` (29.4.2), `<ranges>` (25.2), or `<utility>` (22.2.1) are included.

```
template<size_t I, class T> struct tuple_element<I, const T>;
```

7 Let `TE` denote `tuple_element_t<I, T>` of the cv-unqualified type `T`. Then each specialization of the template meets the *Cpp17TransformationTrait* requirements (21.3.2) with a member typedef `type` that names the type `const TE`.

8 In addition to being available via inclusion of the `<tuple>` header, the template is available when any of the headers `<array>` (23.3.2), `<complex>` (29.4.2), `<ranges>` (25.2), or `<utility>` (22.2.1) are included.

22.4.8 Element access [tuple.elem]

```
template<size_t I, class... Types>
  constexpr tuple_element_t<I, tuple<Types...>>&
    get(tuple<Types...>& t) noexcept;
template<size_t I, class... Types>
  constexpr tuple_element_t<I, tuple<Types...>>&&
    get(tuple<Types...>&& t) noexcept;        // #1
template<size_t I, class... Types>
  constexpr const tuple_element_t<I, tuple<Types...>>&
    get(const tuple<Types...>& t) noexcept;   // #2
template<size_t I, class... Types>
  constexpr const tuple_element_t<I, tuple<Types...>>&& get(const tuple<Types...>&& t) noexcept;
```

1 *Mandates*: `I` < `sizeof...(Types)`.

2 *Returns*: A reference to the `I`$^{\text{th}}$ element of `t`, where indexing is zero-based.

3 [*Note 1*: For the overload marked #1, if a type `T` in `Types` is some reference type `X&`, the return type is `X&`, not `X&&`. However, if the element type is a non-reference type `T`, the return type is `T&&`. — *end note*]

4 [*Note 2*: Constness is shallow. For the overload marked #2, if a type `T` in `Types` is some reference type `X&`, the return type is `X&`, not `const X&`. However, if the element type is a non-reference type `T`, the return type is `const T&`. This is consistent with how constness is defined to work for non-static data members of reference type. — *end note*]

```
template<class T, class... Types>
  constexpr T& get(tuple<Types...>& t) noexcept;
template<class T, class... Types>
  constexpr T&& get(tuple<Types...>&& t) noexcept;
template<class T, class... Types>
  constexpr const T& get(const tuple<Types...>& t) noexcept;
template<class T, class... Types>
  constexpr const T&& get(const tuple<Types...>&& t) noexcept;
```

5 *Mandates*: The type `T` occurs exactly once in `Types`.

6 *Returns*: A reference to the element of `t` corresponding to the type `T` in `Types`.

7 [*Example 1*:

```
const tuple<int, const int, double, double> t(1, 2, 3.4, 5.6);
const int& i1 = get<int>(t);                    // OK, i1 has value 1
const int& i2 = get<const int>(t);              // OK, i2 has value 2
const double& d = get<double>(t);               // error: type double is not unique within t
```

— *end example*]

8 [*Note 3*: The reason `get` is a non-member function is that if this functionality had been provided as a member function, code where the type depended on a template parameter would have required using the `template` keyword. — *end note*]

22.4.9 Relational operators [tuple.rel]

```
template<class... TTypes, class... UTypes>
  constexpr bool operator==(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
template<class... TTypes, tuple-like UTuple>
  constexpr bool operator==(const tuple<TTypes...>& t, const UTuple& u);
```

1 For the first overload let `UTuple` be `tuple<UTypes...>`.

2 *Constraints*: For all `i`, where $0 \leq$ `i` $<$ `sizeof...(TTypes)`, `get<i>(t) == get<i>(u)` is a valid expression and `decltype(get<i>(t) == get<i>(u))` models *`boolean-testable`*. `sizeof...(TTypes)` equals `tuple_size_v<UTuple>`.

3 *Returns*: `true` if `get<i>(t) == get<i>(u)` for all `i`, otherwise `false`.

[*Note 1*: If `sizeof...(TTypes)` equals zero, returns `true`. — *end note*]

4 *Remarks*:

(4.1) — The elementary comparisons are performed in order from the zeroth index upwards. No comparisons or element accesses are performed after the first equality comparison that evaluates to `false`.

(4.2) — The second overload is to be found via argument-dependent lookup (6.5.4) only.

```
template<class... TTypes, class... UTypes>
  constexpr common_comparison_category_t<synth-three-way-result<TTypes, UTypes>...>
    operator<=>(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
template<class... TTypes, tuple-like UTuple>
  constexpr common_comparison_category_t<synth-three-way-result<TTypes, Elems>...>
    operator<=>(const tuple<TTypes...>& t, const UTuple& u);
```

5 For the second overload, `Elems` denotes the pack of types `tuple_element_t<0, UTuple>`, `tuple_element_t<1, UTuple>`, ..., `tuple_element_t<tuple_size_v<UTuple> - 1, UTuple>`.

6 *Effects*: Performs a lexicographical comparison between `t` and `u`. If `sizeof...(TTypes)` equals zero, returns `strong_ordering::equal`. Otherwise, equivalent to:

```
if (auto c = synth-three-way(get<0>(t), get<0>(u)); c != 0) return c;
return t_tail <=> u_tail;
```

where $\texttt{r}_{\text{tail}}$ for some `r` is a tuple containing all but the first element of `r`.

7 *Remarks*: The second overload is to be found via argument-dependent lookup (6.5.4) only.

8 [*Note 2*: The above definition does not require $\texttt{t}_{\text{tail}}$ (or $\texttt{u}_{\text{tail}}$) to be constructed. It might not even be possible, as `t` and `u` are not required to be copy constructible. Also, all comparison operator functions are short circuited; they do not perform element accesses beyond what is needed to determine the result of the comparison. — *end note*]

22.4.10 `common_reference` related specializations [tuple.common.ref]

1 In the descriptions that follow:

(1.1) — Let `TTypes` be a pack formed by the sequence of `tuple_element_t<`i`, TTuple>` for every integer $0 \leq i <$ `tuple_size_v<TTuple>`.

(1.2) — Let `UTypes` be a pack formed by the sequence of `tuple_element_t<`i`, UTuple>` for every integer $0 \leq i <$ `tuple_size_v<UTuple>`.

```
template<tuple-like TTuple, tuple-like UTuple,
         template<class> class TQual, template<class> class UQual>
struct basic_common_reference<TTuple, UTuple, TQual, UQual> {
  using type = see below;
};
```

2 *Constraints*:

(2.1) — `TTuple` is a specialization of `tuple` or `UTuple` is a specialization of `tuple`.

(2.2) — `is_same_v<TTuple, decay_t<TTuple>>` is `true`.

(2.3) — `is_same_v<UTuple, decay_t<UTuple>>` is `true`.

(2.4) — `tuple_size_v<TTuple>` equals `tuple_size_v<UTuple>`.

(2.5) — `tuple<common_reference_t<TQual<TTypes>, UQual<UTypes>>...>` denotes a type.

3 *Result*: The member *typedef-name* `type` denotes the type `tuple<common_reference_t<TQual<TTypes>, UQual<UTypes>>...>`.

```
template<tuple-like TTuple, tuple-like UTuple>
struct common_type<TTuple, UTuple> {
  using type = see below;
};
```

4 *Constraints*:

(4.1) — `TTuple` is a specialization of `tuple` or `UTuple` is a specialization of `tuple`.

(4.2) — `is_same_v<TTuple, decay_t<TTuple>>` is `true`.

(4.3) — `is_same_v<UTuple, decay_t<UTuple>>` is `true`.

(4.4) — `tuple_size_v<TTuple>` equals `tuple_size_v<UTuple>`.

(4.5) — `tuple<common_type_t<TTypes, UTypes>...>` denotes a type.

5 *Result*: The member *typedef-name* `type` denotes the type `tuple<common_type_t<TTypes, UTypes>...>`.

22.4.11 Tuple traits [tuple.traits]

```
template<class... Types, class Alloc>
  struct uses_allocator<tuple<Types...>, Alloc> : true_type { };
```

1 *Preconditions*: `Alloc` meets the *Cpp17Allocator* requirements (16.4.4.6.1).

2 [*Note 1*: Specialization of this trait informs other library components that `tuple` can be constructed with an allocator, even though it does not have a nested `allocator_type`. — *end note*]

22.4.12 Tuple specialized algorithms [tuple.special]

```
template<class... Types>
  constexpr void swap(tuple<Types...>& x, tuple<Types...>& y) noexcept(see below);
template<class... Types>
  constexpr void swap(const tuple<Types...>& x, const tuple<Types...>& y) noexcept(see below);
```

1 *Constraints*:

(1.1) — For the first overload, `(is_swappable_v<Types> && ...)` is `true`.

(1.2) — For the second overload, `(is_swappable_v<const Types> && ...)` is `true`.

2 *Effects*: As if by `x.swap(y)`.

3 *Remarks*: The exception specification is equivalent to:

```
noexcept(x.swap(y))
```

22.5 Optional objects [optional]

22.5.1 General [optional.general]

1 Subclause 22.5 describes class template `optional` that represents optional objects. An *optional object* is an object that contains the storage for another object and manages the lifetime of this contained object, if any. The contained object may be initialized after the optional object has been initialized, and may be destroyed before the optional object has been destroyed. The initialization state of the contained object is tracked by the optional object.

22.5.2 Header `<optional>` synopsis [optional.syn]

```
// mostly freestanding
#include <compare>              // see 17.12.1

namespace std {
  // 22.5.3, class template optional
  template<class T>
    class optional;                                          // partially freestanding

  // 22.5.4, partial specialization of optional for lvalue reference types
  template<class T>
    class optional<T&>;                                      // partially freestanding

  template<class T>
    constexpr bool ranges::enable_view<optional<T>> = true;
  template<class T>
    constexpr auto format_kind<optional<T>> = range_format::disabled;
  template<class T>
    constexpr bool ranges::enable_borrowed_range<optional<T&>> = true;
```

```
template<class T>
  concept is-derived-from-optional = requires(const T& t) {   // exposition only
    []<class U>(const optional<U>&){ }(t);
  };

// 22.5.5, no-value state indicator
struct nullopt_t{see below};
inline constexpr nullopt_t nullopt(unspecified);

// 22.5.6, class bad_optional_access
class bad_optional_access;

  // 22.5.11, hash support
  template<class T> struct hash;
  template<class T> struct hash<optional<T>>;
}
```

22.5.3 Class template optional [optional.optional]

22.5.3.1 General [optional.optional.general]

```
namespace std {
  template<class T>
  class optional {
  public:
    using value_type     = T;
    using iterator       = implementation-defined;              // see 22.5.3.6
    using const_iterator = implementation-defined;              // see 22.5.3.6

    // 22.5.3.2, constructors
    constexpr optional() noexcept;
    constexpr optional(nullopt_t) noexcept;
    constexpr optional(const optional&);
    constexpr optional(optional&&) noexcept(see below);
    template<class... Args>
      constexpr explicit optional(in_place_t, Args&&...);
    template<class U, class... Args>
      constexpr explicit optional(in_place_t, initializer_list<U>, Args&&...);
    template<class U = remove_cv_t<T>>
      constexpr explicit(see below) optional(U&&);
    template<class U>
      constexpr explicit(see below) optional(const optional<U>&);
    template<class U>
      constexpr explicit(see below) optional(optional<U>&&);

    // 22.5.3.3, destructor
    constexpr ~optional();

    // 22.5.3.4, assignment
    constexpr optional& operator=(nullopt_t) noexcept;
    constexpr optional& operator=(const optional&);
    constexpr optional& operator=(optional&&) noexcept(see below);
    template<class U = remove_cv_t<T>> constexpr optional& operator=(U&&);

    template<class U> constexpr optional& operator=(optional<U>&&);
    template<class... Args> constexpr T& emplace(Args&&...);
    template<class U, class... Args> constexpr T& emplace(initializer_list<U>, Args&&...);

    // 22.5.3.5, swap
    constexpr void swap(optional&) noexcept(see below);

    // 22.5.3.6, iterator support
    constexpr iterator begin() noexcept;
    constexpr const_iterator begin() const noexcept;
    constexpr iterator end() noexcept;
    constexpr const_iterator end() const noexcept;

    // 22.5.3.7, observers
    constexpr const T* operator->() const noexcept;
    constexpr T* operator->() noexcept;
    constexpr const T& operator*() const & noexcept;
    constexpr T& operator*() & noexcept;
    constexpr T&& operator*() && noexcept;
    constexpr const T&& operator*() const && noexcept;
    constexpr explicit operator bool() const noexcept;
    constexpr bool has_value() const noexcept;
    constexpr const T& value() const &;                         // freestanding-deleted
```

```
    constexpr T& value() &;                                          // freestanding-deleted
    constexpr T&& value() &&;                                        // freestanding-deleted
    constexpr const T&& value() const &&;                            // freestanding-deleted
    template<class U = remove_cv_t<T>> constexpr T value_or(U&&) const &;
    template<class U = remove_cv_t<T>> constexpr T value_or(U&&) &&;

    // 22.5.3.8, monadic operations
    template<class F> constexpr auto and_then(F&& f) &;
    template<class F> constexpr auto and_then(F&& f) &&;
    template<class F> constexpr auto and_then(F&& f) const &;
    template<class F> constexpr auto and_then(F&& f) const &&;
    template<class F> constexpr auto transform(F&& f) &;
    template<class F> constexpr auto transform(F&& f) &&;
    template<class F> constexpr auto transform(F&& f) const &;
    template<class F> constexpr auto transform(F&& f) const &&;
    template<class F> constexpr optional or_else(F&& f) &&;
    template<class F> constexpr optional or_else(F&& f) const &;

    // 22.5.3.9, modifiers
    constexpr void reset() noexcept;

  private:
    union {
      remove_cv_t<T> val;        // exposition only
    };
  };

  template<class T>
    optional(T) -> optional<T>;
}
```

1 An instance of `optional<T>` is said to *contain a value* when and only when its member *`val`* is active (11.5.1); *`val`* is referred to as its *contained value*. An optional object's contained value is nested within (6.8.2) the optional object.

2 A type `X` is a *valid contained type* for `optional` if `X` is an lvalue reference type or a complete non-array object type, and `remove_cvref_t<X>` is a type other than `in_place_t` or `nullopt_t`. If a specialization of `optional` is instantiated with a type `T` that is not a valid contained type for `optional`, the program is ill-formed. If `T` is an object type, `T` shall meet the *Cpp17Destructible* requirements (Table 35).

22.5.3.2 Constructors [optional.ctor]

1 The exposition-only variable template *`converts-from-any-cvref`* is used by some constructors for `optional`.

```
template<class T, class W>
constexpr bool converts-from-any-cvref =  // exposition only
  disjunction_v<is_constructible<T, W&>, is_convertible<W&, T>,
                is_constructible<T, W>, is_convertible<W, T>,
                is_constructible<T, const W&>, is_convertible<const W&, T>,
                is_constructible<T, const W>, is_convertible<const W, T>>;

constexpr optional() noexcept;
constexpr optional(nullopt_t) noexcept;
```

2 *Postconditions*: `*this` does not contain a value.

3 *Remarks*: No contained value is initialized. For every object type `T` these constructors are constexpr constructors (9.2.6).

```
constexpr optional(const optional& rhs);
```

4 *Effects*: If `rhs` contains a value, direct-non-list-initializes *`val`* with `rhs.val`.

5 *Postconditions*: `rhs.has_value() == this->has_value()`.

6 *Throws*: Any exception thrown by the selected constructor of `T`.

7 *Remarks*: This constructor is defined as deleted unless `is_copy_constructible_v<T>` is `true`. If `is_trivially_copy_constructible_v<T>` is `true`, this constructor is trivial.

```
constexpr optional(optional&& rhs) noexcept(see below);
```

8 *Constraints*: `is_move_constructible_v<T>` is `true`.

9 *Effects*: If `rhs` contains a value, direct-non-list-initializes *val* with `std::move(rhs.`*val*`)`. `rhs.has_value()` is unchanged.

10 *Postconditions*: `rhs.has_value() == this->has_value()`.

11 *Throws*: Any exception thrown by the selected constructor of `T`.

12 *Remarks*: The exception specification is equivalent to `is_nothrow_move_constructible_v<T>`. If `is_trivially_move_constructible_v<T>` is `true`, this constructor is trivial.

```
template<class... Args> constexpr explicit optional(in_place_t, Args&&... args);
```

13 *Constraints*: `is_constructible_v<T, Args...>` is `true`.

14 *Effects*: Direct-non-list-initializes *val* with `std::forward<Args>(args)...`.

15 *Postconditions*: `*this` contains a value.

16 *Throws*: Any exception thrown by the selected constructor of `T`.

17 *Remarks*: If `T`'s constructor selected for the initialization is a constexpr constructor, this constructor is a constexpr constructor.

```
template<class U, class... Args>
  constexpr explicit optional(in_place_t, initializer_list<U> il, Args&&... args);
```

18 *Constraints*: `is_constructible_v<T, initializer_list<U>&, Args...>` is `true`.

19 *Effects*: Direct-non-list-initializes *val* with `il, std::forward<Args>(args)...`.

20 *Postconditions*: `*this` contains a value.

21 *Throws*: Any exception thrown by the selected constructor of `T`.

22 *Remarks*: If `T`'s constructor selected for the initialization is a constexpr constructor, this constructor is a constexpr constructor.

```
template<class U = remove_cv_t<T>> constexpr explicit(see below) optional(U&& v);
```

23 *Constraints*:

(23.1) — `is_constructible_v<T, U>` is `true`,

(23.2) — `is_same_v<remove_cvref_t<U>, in_place_t>` is `false`,

(23.3) — `is_same_v<remove_cvref_t<U>, optional>` is `false`, and

(23.4) — if `T` is *cv* `bool`, `remove_cvref_t<U>` is not a specialization of `optional`.

24 *Effects*: Direct-non-list-initializes *val* with `std::forward<U>(v)`.

25 *Postconditions*: `*this` contains a value.

26 *Throws*: Any exception thrown by the selected constructor of `T`.

27 *Remarks*: If `T`'s selected constructor is a constexpr constructor, this constructor is a constexpr constructor. The expression inside `explicit` is equivalent to:

```
!is_convertible_v<U, T>
```

```
template<class U> constexpr explicit(see below) optional(const optional<U>& rhs);
```

28 *Constraints*:

(28.1) — `is_constructible_v<T, const U&>` is `true`, and

(28.2) — if `T` is not *cv* `bool`, *converts-from-any-cvref*`<T, optional<U>>` is `false`.

29 *Effects*: If `rhs` contains a value, direct-non-list-initializes *val* with `rhs.operator*()`.

30 *Postconditions*: `rhs.has_value() == this->has_value()`.

31 *Throws*: Any exception thrown by the selected constructor of `T`.

32 *Remarks*: The expression inside `explicit` is equivalent to:

```
!is_convertible_v<const U&, T>
```

```
template<class U> constexpr explicit(see below) optional(optional<U>&& rhs);
```

33 *Constraints*:

(33.1) — `is_constructible_v<T, U>` is `true`, and

(33.2) — if `T` is not *cv* `bool`, *`converts-from-any-cvref`*`<T, optional<U>>` is `false`.

34 *Effects*: If `rhs` contains a value, direct-non-list-initializes *`val`* with `std::move(rhs).operator*()`. `rhs.has_value()` is unchanged.

35 *Postconditions*: `rhs.has_value() == this->has_value()`.

36 *Throws*: Any exception thrown by the selected constructor of `T`.

37 *Remarks*: The expression inside `explicit` is equivalent to:

```
!is_convertible_v<U, T>
```

22.5.3.3 Destructor [optional.dtor]

```
constexpr ~optional();
```

1 *Effects*: If `is_trivially_destructible_v<T>` is `false` and `*this` contains a value, calls *`val`*`.T::~T()`.

2 *Remarks*: If `is_trivially_destructible_v<T>` is `true`, then this destructor is trivial.

22.5.3.4 Assignment [optional.assign]

```
constexpr optional<T>& operator=(nullopt_t) noexcept;
```

1 *Effects*: If `*this` contains a value, calls *`val`*`.T::~T()` to destroy the contained value; otherwise no effect.

2 *Postconditions*: `*this` does not contain a value.

3 *Returns*: `*this`.

```
constexpr optional<T>& operator=(const optional& rhs);
```

4 *Effects*: See Table 67.

Table 67 — `optional::operator=(const optional&)` effects [tab:optional.assign.copy]

	`*this` contains a value	**`*this` does not contain a value**
`rhs` contains a value	assigns `rhs.`*`val`* to *`val`*	direct-non-list-initializes *`val`* with `rhs.`*`val`*
`rhs` does not contain a value	destroys the contained value by calling *`val`*`.T::~T()`	no effect

5 *Postconditions*: `rhs.has_value() == this->has_value()`.

6 *Returns*: `*this`.

7 *Remarks*: If any exception is thrown, the result of the expression `this->has_value()` remains unchanged. If an exception is thrown during the call to `T`'s copy constructor, no effect. If an exception is thrown during the call to `T`'s copy assignment, the state of its contained value is as defined by the exception safety guarantee of `T`'s copy assignment. This operator is defined as deleted unless `is_copy_constructible_v<T>` is `true` and `is_copy_assignable_v<T>` is `true`. If `is_trivially_copy_constructible_v<T> && is_trivially_copy_assignable_v<T> && is_trivially_destructible_v<T>` is `true`, this assignment operator is trivial.

```
constexpr optional& operator=(optional&& rhs) noexcept(see below);
```

8 *Constraints*: `is_move_constructible_v<T>` is `true` and `is_move_assignable_v<T>` is `true`.

9 *Effects*: See Table 68. The result of the expression `rhs.has_value()` remains unchanged.

Table 68 — `optional::operator=(optional&&)` effects **[tab:optional.assign.move]**

	***this contains a value**	***this does not contain a value**
rhs contains a value	assigns `std::move(rhs.`*val*`)` to *val*	direct-non-list-initializes *val* with `std::move(rhs.`*val*`)`
rhs does not contain a value	destroys the contained value by calling *val*`.T::~T()`	no effect

10 *Postconditions*: `rhs.has_value() == this->has_value()`.

11 *Returns*: `*this`.

12 *Remarks*: The exception specification is equivalent to:

```
is_nothrow_move_assignable_v<T> && is_nothrow_move_constructible_v<T>
```

13 If any exception is thrown, the result of the expression `this->has_value()` remains unchanged. If an exception is thrown during the call to `T`'s move constructor, the state of `rhs.`*val* is determined by the exception safety guarantee of `T`'s move constructor. If an exception is thrown during the call to `T`'s move assignment, the states of *val* and `rhs.`*val* are determined by the exception safety guarantee of `T`'s move assignment. If `is_trivially_move_constructible_v<T> && is_trivially_move_assignable_v<T> && is_trivially_destructible_v<T>` is `true`, this assignment operator is trivial.

```
template<class U = remove_cv_t<T>> constexpr optional& operator=(U&& v);
```

14 *Constraints*:

(14.1) — `is_same_v<remove_cvref_t<U>, optional>` is `false`,

(14.2) — `conjunction_v<is_scalar<T>, is_same<T, decay_t<U>>>` is `false`,

(14.3) — `is_constructible_v<T, U>` is `true`, and

(14.4) — `is_assignable_v<T&, U>` is `true`.

15 *Effects*: If `*this` contains a value, assigns `std::forward<U>(v)` to *val*; otherwise direct-non-list-initializes *val* with `std::forward<U>(v)`.

16 *Postconditions*: `*this` contains a value.

17 *Returns*: `*this`.

18 *Remarks*: If any exception is thrown, the result of the expression `this->has_value()` remains unchanged. If an exception is thrown during the call to `T`'s constructor, the state of `v` is determined by the exception safety guarantee of `T`'s constructor. If an exception is thrown during the call to `T`'s assignment, the states of *val* and `v` are determined by the exception safety guarantee of `T`'s assignment.

```
template<class U> constexpr optional<T>& operator=(const optional<U>& rhs);
```

19 *Constraints*:

(19.1) — `is_constructible_v<T, const U&>` is `true`,

(19.2) — `is_assignable_v<T&, const U&>` is `true`,

(19.3) — *converts-from-any-cvref*`<T, optional<U>>` is `false`,

(19.4) — `is_assignable_v<T&, optional<U>&>` is `false`,

(19.5) — `is_assignable_v<T&, optional<U>&&>` is `false`,

(19.6) — `is_assignable_v<T&, const optional<U>&>` is `false`, and

(19.7) — `is_assignable_v<T&, const optional<U>&&>` is `false`.

20 *Effects*: See Table 69.

21 *Postconditions*: `rhs.has_value() == this->has_value()`.

22 *Returns*: `*this`.

23 *Remarks*: If any exception is thrown, the result of the expression `this->has_value()` remains unchanged. If an exception is thrown during the call to `T`'s constructor, the state of `rhs.`*val* is determined

Table 69 — `optional::operator=(const optional<U>&)` effects [tab:optional.assign.copy.templ]

	***this contains a value**	***this does not contain a value**
rhs contains a value	assigns `rhs.operator*()` to *val*	direct-non-list-initializes *val* with `rhs.operator*()`
rhs does not contain a value	destroys the contained value by calling *val*`.T::~T()`	no effect

by the exception safety guarantee of `T`'s constructor. If an exception is thrown during the call to `T`'s assignment, the states of *val* and `rhs.`*val* are determined by the exception safety guarantee of `T`'s assignment.

```
template<class U> constexpr optional<T>& operator=(optional<U>&& rhs);
```

24 *Constraints*:

(24.1) — `is_constructible_v<T, U>` is `true`,

(24.2) — `is_assignable_v<T&, U>` is `true`,

(24.3) — *converts-from-any-cvref*`<T, optional<U>>` is `false`,

(24.4) — `is_assignable_v<T&, optional<U>&>` is `false`,

(24.5) — `is_assignable_v<T&, optional<U>&&>` is `false`,

(24.6) — `is_assignable_v<T&, const optional<U>&>` is `false`, and

(24.7) — `is_assignable_v<T&, const optional<U>&&>` is `false`.

25 *Effects*: See Table 70. The result of the expression `rhs.has_value()` remains unchanged.

Table 70 — `optional::operator=(optional<U>&&)` effects [tab:optional.assign.move.templ]

	***this contains a value**	***this does not contain a value**
rhs contains a value	assigns `std::move(rhs).operator*()` to *val*	direct-non-list-initializes *val* with `std::move(rhs).operator*()`
rhs does not contain a value	destroys the contained value by calling *val*`.T::~T()`	no effect

26 *Postconditions*: `rhs.has_value() == this->has_value()`.

27 *Returns*: `*this`.

28 *Remarks*: If any exception is thrown, the result of the expression `this->has_value()` remains unchanged. If an exception is thrown during the call to `T`'s constructor, the state of `rhs.`*val* is determined by the exception safety guarantee of `T`'s constructor. If an exception is thrown during the call to `T`'s assignment, the states of *val* and `rhs.`*val* are determined by the exception safety guarantee of `T`'s assignment.

```
template<class... Args> constexpr T& emplace(Args&&... args);
```

29 *Constraints*: `is_constructible_v<T, Args...>` is `true`.

30 *Effects*: Calls `*this = nullopt`. Then direct-non-list-initializes *val* with `std::forward<Args>(args)...`.

31 *Postconditions*: `*this` contains a value.

32 *Returns*: *val*`.`

33 *Throws*: Any exception thrown by the selected constructor of `T`.

34 *Remarks*: If an exception is thrown during the call to `T`'s constructor, `*this` does not contain a value, and the previous *`val`* (if any) has been destroyed.

```
template<class U, class... Args> constexpr T& emplace(initializer_list<U> il, Args&&... args);
```

35 *Constraints*: `is_constructible_v<T, initializer_list<U>&, Args...>` is `true`.

36 *Effects*: Calls `*this = nullopt`. Then direct-non-list-initializes *`val`* with `il, std::forward<Args>(args)...`.

37 *Postconditions*: `*this` contains a value.

38 *Returns*: *`val`*.

39 *Throws*: Any exception thrown by the selected constructor of `T`.

40 *Remarks*: If an exception is thrown during the call to `T`'s constructor, `*this` does not contain a value, and the previous *`val`* (if any) has been destroyed.

22.5.3.5 Swap [optional.swap]

```
constexpr void swap(optional& rhs) noexcept(see below);
```

1 *Mandates*: `is_move_constructible_v<T>` is `true`.

2 *Preconditions*: `T` meets the *Cpp17Swappable* requirements (16.4.4.3).

3 *Effects*: See Table 71.

Table 71 — `optional::swap(optional&)` effects [tab:optional.swap]

	`*this` contains a value	**`*this` does not contain a value**
`rhs` contains a value	calls `swap(`*`val`*`, rhs.`*`val`*`)`	direct-non-list-initializes *`val`* with `std::move(rhs.`*`val`*`)`, followed by `rhs.`*`val`*`.T::~T()`; postcondition is that `*this` contains a value and `rhs` does not contain a value
`rhs` does not contain a value	direct-non-list-initializes `rhs.`*`val`* with `std::move(`*`val`*`)`, followed by *`val`*`.T::~T()`; postcondition is that `*this` does not contain a value and `rhs` contains a value	no effect

4 *Throws*: Any exceptions thrown by the operations in the relevant part of Table 71.

5 *Remarks*: The exception specification is equivalent to:

```
is_nothrow_move_constructible_v<T> && is_nothrow_swappable_v<T>
```

6 If any exception is thrown, the results of the expressions `this->has_value()` and `rhs.has_value()` remain unchanged. If an exception is thrown during the call to function `swap`, the states of *`val`* and `rhs.`*`val`* are determined by the exception safety guarantee of `swap` for lvalues of `T`. If an exception is thrown during the call to `T`'s move constructor, the states of *`val`* and `rhs.`*`val`* are determined by the exception safety guarantee of `T`'s move constructor.

22.5.3.6 Iterator support [optional.iterators]

```
using iterator       = implementation-defined;
using const_iterator = implementation-defined;
```

1 These types model `contiguous_iterator` (24.3.4.14), meet the *Cpp17RandomAccessIterator* requirements (24.3.5.7), and meet the requirements for constexpr iterators (24.3.1), with value type `remove_cv_t<T>`. The reference type is `T&` for `iterator` and `const T&` for `const_iterator`.

2 All requirements on container iterators (23.2.2.2) apply to `optional::iterator` and `optional::const_iterator` as well.

3 Any operation that initializes or destroys the contained value of an optional object invalidates all iterators into that object.

```
constexpr iterator begin() noexcept;
constexpr const_iterator begin() const noexcept;
```

4 *Returns*: If `has_value()` is `true`, an iterator referring to the contained value. Otherwise, a past-the-end iterator value.

```
constexpr iterator end() noexcept;
constexpr const_iterator end() const noexcept;
```

5 *Returns*: `begin() + has_value()`.

22.5.3.7 Observers [optional.observe]

```
constexpr const T* operator->() const noexcept;
constexpr T* operator->() noexcept;
```

1 *Hardened preconditions*: `has_value()` is `true`.

2 *Returns*: `addressof(`*`val`*`)`.

3 *Remarks*: These functions are constexpr functions.

```
constexpr const T& operator*() const & noexcept;
constexpr T& operator*() & noexcept;
```

4 *Hardened preconditions*: `has_value()` is `true`.

5 *Returns*: *`val`*.

6 *Remarks*: These functions are constexpr functions.

```
constexpr T&& operator*() && noexcept;
constexpr const T&& operator*() const && noexcept;
```

7 *Hardened preconditions*: `has_value()` is `true`.

8 *Effects*: Equivalent to: `return std::move(`*`val`*`);`

```
constexpr explicit operator bool() const noexcept;
```

9 *Returns*: `true` if and only if `*this` contains a value.

10 *Remarks*: This function is a constexpr function.

```
constexpr bool has_value() const noexcept;
```

11 *Returns*: `true` if and only if `*this` contains a value.

12 *Remarks*: This function is a constexpr function.

```
constexpr const T& value() const &;
constexpr T& value() &;
```

13 *Effects*: Equivalent to:

```
return has_value() ? val : throw bad_optional_access();
```

```
constexpr T&& value() &&;
constexpr const T&& value() const &&;
```

14 *Effects*: Equivalent to:

```
return has_value() ? std::move(val) : throw bad_optional_access();
```

```
template<class U = remove_cv_t<T>> constexpr T value_or(U&& v) const &;
```

15 *Mandates*: `is_copy_constructible_v<T> && is_convertible_v<U&&, T>` is `true`.

16 *Effects*: Equivalent to:

```
return has_value() ? val : static_cast<T>(std::forward<U>(v));
```

```
template<class U = remove_cv_t<T>> constexpr T value_or(U&& v) &&;
```

17 *Mandates*: `is_move_constructible_v<T> && is_convertible_v<U&&, T>` is `true`.

18 *Effects*: Equivalent to:

```
return has_value() ? std::move(val) : static_cast<T>(std::forward<U>(v));
```

22.5.3.8 Monadic operations [optional.monadic]

```
template<class F> constexpr auto and_then(F&& f) &;
template<class F> constexpr auto and_then(F&& f) const &;
```

1 Let `U` be `invoke_result_t<F, decltype((val))>`.

2 *Mandates*: `remove_cvref_t<U>` is a specialization of `optional`.

3 *Effects*: Equivalent to:

```
if (*this) {
  return invoke(std::forward<F>(f), val);
} else {
  return remove_cvref_t<U>();
}
```

```
template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &&;
```

4 Let `U` be `invoke_result_t<F, decltype(std::move(val))>`.

5 *Mandates*: `remove_cvref_t<U>` is a specialization of `optional`.

6 *Effects*: Equivalent to:

```
if (*this) {
  return invoke(std::forward<F>(f), std::move(val));
} else {
  return remove_cvref_t<U>();
}
```

```
template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) const &;
```

7 Let `U` be `remove_cv_t<invoke_result_t<F, decltype((val))>>`.

8 *Mandates*: `U` is a valid contained type for `optional`. The declaration

```
U u(invoke(std::forward<F>(f), val));
```

is well-formed for some invented variable `u`.

[*Note 1*: There is no requirement that `U` is movable (9.5.1). — *end note*]

9 *Returns*: If `*this` contains a value, an `optional<U>` object whose contained value is direct-non-list-initialized with `invoke(std::forward<F>(f), val)`; otherwise, `optional<U>()`.

```
template<class F> constexpr auto transform(F&& f) &&;
template<class F> constexpr auto transform(F&& f) const &&;
```

10 Let `U` be `remove_cv_t<invoke_result_t<F, decltype(std::move(val))>>`.

11 *Mandates*: `U` is a valid contained type for `optional`. The declaration

```
U u(invoke(std::forward<F>(f), std::move(val)));
```

is well-formed for some invented variable `u`.

[*Note 2*: There is no requirement that `U` is movable (9.5.1). — *end note*]

12 *Returns*: If `*this` contains a value, an `optional<U>` object whose contained value is direct-non-list-initialized with `invoke(std::forward<F>(f), std::move(val))`; otherwise, `optional<U>()`.

```
template<class F> constexpr optional or_else(F&& f) const &;
```

13 *Constraints*: `F` models `invocable` and `T` models `copy_constructible`.

14 *Mandates*: `is_same_v<remove_cvref_t<invoke_result_t<F>>, optional>` is `true`.

15 *Effects*: Equivalent to:

```
  if (*this) {
    return *this;
  } else {
    return std::forward<F>(f)();
  }
```

```
template<class F> constexpr optional or_else(F&& f) &&;
```

16 *Constraints*: `F` models `invocable` and `T` models `move_constructible`.

17 *Mandates*: `is_same_v<remove_cvref_t<invoke_result_t<F>>, optional>` is `true`.

18 *Effects*: Equivalent to:

```
  if (*this) {
    return std::move(*this);
  } else {
    return std::forward<F>(f)();
  }
```

22.5.3.9 Modifiers [optional.mod]

```
constexpr void reset() noexcept;
```

1 *Effects*: If `*this` contains a value, calls *val*`.T::~T()` to destroy the contained value; otherwise no effect.

2 *Postconditions*: `*this` does not contain a value.

22.5.4 Partial specialization of `optional` for reference types [optional.optional.ref]

22.5.4.1 General [optional.optional.ref.general]

```
namespace std {
  template<class T>
  class optional<T&> {
  public:
    using value_type = T;
    using iterator   = implementation-defined;  // present only if T is an object type other than an array
                                                // of unknown bound; see 22.5.4.5

    // 22.5.4.2, constructors
    constexpr optional() noexcept = default;
    constexpr optional(nullopt_t) noexcept : optional() {}
    constexpr optional(const optional& rhs) noexcept = default;

    template<class Arg>
      constexpr explicit optional(in_place_t, Arg&& arg);
    template<class U>
      constexpr explicit(see below) optional(U&& u) noexcept(see below);
    template<class U>
      constexpr explicit(see below) optional(optional<U>& rhs) noexcept(see below);
    template<class U>
      constexpr explicit(see below) optional(const optional<U>& rhs) noexcept(see below);
    template<class U>
      constexpr explicit(see below) optional(optional<U>&& rhs) noexcept(see below);
    template<class U>
      constexpr explicit(see below) optional(const optional<U>&& rhs) noexcept(see below);

    constexpr ~optional() = default;

    // 22.5.4.3, assignment
    constexpr optional& operator=(nullopt_t) noexcept;
    constexpr optional& operator=(const optional& rhs) noexcept = default;

    template<class U> constexpr T& emplace(U&& u) noexcept(see below);

    // 22.5.4.4, swap
    constexpr void swap(optional& rhs) noexcept;
```

```
    // 22.5.4.5, iterator support
    constexpr auto begin() const noexcept;
    constexpr auto end() const noexcept;

    // 22.5.4.6, observers
    constexpr T*       operator->() const noexcept;
    constexpr T&       operator*() const noexcept;
    constexpr explicit operator bool() const noexcept;
    constexpr bool     has_value() const noexcept;
    constexpr T&       value() const;                              // freestanding-deleted
    template<class U = remove_cv_t<T>>
      constexpr remove_cv_t<T> value_or(U&& u) const;

    // 22.5.4.7, monadic operations
    template<class F> constexpr auto and_then(F&& f) const;
    template<class F> constexpr optional<invoke_result_t<F, T&>> transform(F&& f) const;
    template<class F> constexpr optional or_else(F&& f) const;

    // 22.5.4.8, modifiers
    constexpr void reset() noexcept;

  private:
    T* val = nullptr;                                              // exposition only

    // 22.5.4.9, exposition only helper functions
    template<class U>
      constexpr void convert-ref-init-val(U&& u);                  // exposition only
  };
}
```

1 An object of type `optional<T&>` *contains a value* if and only if *`val`* `!= nullptr` is `true`. When an `optional<T&>` contains a value, the *contained value* is a reference to `*`*`val`*.

2 Each type `optional<T&>` is a trivially copyable class (11.2).

22.5.4.2 Constructors [optional.ref.ctor]

```
template<class Arg>
  constexpr explicit optional(in_place_t, Arg&& arg);
```

1 *Constraints*:

(1.1) — `is_constructible_v<T&, Arg>` is `true`, and

(1.2) — `reference_constructs_from_temporary_v<T&, Arg>` is `false`.

2 *Effects*: Equivalent to: *`convert-ref-init-val`*`(std::forward<Arg>(arg))`.

3 *Postconditions*: `*this` contains a value.

```
template<class U>
  constexpr explicit(!is_convertible_v<U, T&>)
  optional(U&& u) noexcept(is_nothrow_constructible_v<T&, U>);
```

4 *Constraints*:

(4.1) — `is_same_v<remove_cvref_t<U>, optional>` is `false`,

(4.2) — `is_same_v<remove_cvref_t<U>, in_place_t>` is `false`, and

(4.3) — `is_constructible_v<T&, U>` is `true`.

5 *Effects*: Equivalent to: *`convert-ref-init-val`*`(std::forward<U>(u))`.

6 *Postconditions*: `*this` contains a value.

7 *Remarks*: This constructor is defined as deleted if

`reference_constructs_from_temporary_v<T&, U>`

is `true`.

```
template<class U>
  constexpr explicit(!is_convertible_v<U&, T&>)
  optional(optional<U>& rhs) noexcept(is_nothrow_constructible_v<T&, U&>);
```

8 *Constraints*:

(8.1) — `is_same_v<remove_cv_t<T>, optional<U>>` is `false`,

(8.2) — `is_same_v<T&, U>` is `false`, and

(8.3) — `is_constructible_v<T&, U&>` is `true`.

9 *Effects*: Equivalent to:

```
if (rhs.has_value()) convert-ref-init-val(rhs.operator*());
```

10 *Remarks*: This constructor is defined as deleted if

```
reference_constructs_from_temporary_v<T&, U&>
```

is `true`.

```
template<class U>
  constexpr explicit(!is_convertible_v<const U&, T&>)
  optional(const optional<U>& rhs) noexcept(is_nothrow_constructible_v<T&, const U&>);
```

11 *Constraints*:

(11.1) — `is_same_v<remove_cv_t<T>, optional<U>>` is `false`,

(11.2) — `is_same_v<T&, U>` is `false`, and

(11.3) — `is_constructible_v<T&, const U&>` is `true`.

12 *Effects*: Equivalent to:

```
if (rhs.has_value()) convert-ref-init-val(rhs.operator*());
```

13 *Remarks*: This constructor is defined as deleted if

```
reference_constructs_from_temporary_v<T&, const U&>
```

is `true`.

```
template<class U>
  constexpr explicit(!is_convertible_v<U, T&>)
  optional(optional<U>&& rhs) noexcept(is_nothrow_constructible_v<T&, U>);
```

14 *Constraints*:

(14.1) — `is_same_v<remove_cv_t<T>, optional<U>>` is `false`,

(14.2) — `is_same_v<T&, U>` is `false`, and

(14.3) — `is_constructible_v<T&, U>` is `true`.

15 *Effects*: Equivalent to:

```
if (rhs.has_value()) convert-ref-init-val(std::move(rhs).operator*());
```

16 *Remarks*: This constructor is defined as deleted if

```
reference_constructs_from_temporary_v<T&, U>
```

is `true`.

```
template<class U>
  constexpr explicit(!is_convertible_v<const U, T&>)
  optional(const optional<U>&& rhs) noexcept(is_nothrow_constructible_v<T&, const U>);
```

17 *Constraints*:

(17.1) — `is_same_v<remove_cv_t<T>, optional<U>>` is `false`,

(17.2) — `is_same_v<T&, U>` is `false`, and

(17.3) — `is_constructible_v<T&, const U>` is `true`.

18 *Effects*: Equivalent to:

```
if (rhs.has_value()) convert-ref-init-val(std::move(rhs).operator*());
```

19 *Remarks*: This constructor is defined as deleted if

`reference_constructs_from_temporary_v<T&, const U>`

is `true`.

22.5.4.3 Assignment [optional.ref.assign]

```
constexpr optional& operator=(nullopt_t) noexcept;
```

1 *Effects*: Assigns `nullptr` to *`val`*.

2 *Postconditions*: `*this` does not contain a value.

3 *Returns*: `*this`.

```
template<class U>
  constexpr T& emplace(U&& u) noexcept(is_nothrow_constructible_v<T&, U>);
```

4 *Constraints*:

(4.1) — `is_constructible_v<T&, U>` is `true`, and

(4.2) — `reference_constructs_from_temporary_v<T&, U>` is `false`.

5 *Effects*: Equivalent to: *`convert-ref-init-val`*`(std::forward<U>(u))`.

6 *Returns*: *`val`*.

22.5.4.4 Swap [optional.ref.swap]

```
constexpr void swap(optional& rhs) noexcept;
```

1 *Effects*: Equivalent to: `std::swap(`*`val`*`, rhs.`*`val`*`)`.

22.5.4.5 Iterator support [optional.ref.iterators]

```
using iterator = implementation-defined;      // present only if T is an object type other than an array
                                              // of unknown bound
```

1 This type models `contiguous_iterator` (24.3.4.14), meets the *Cpp17RandomAccessIterator* requirements (24.3.5.7), and meets the requirements for constexpr iterators (24.3.1), with value type `remove_cv_t<T>`. The reference type is `T&` for `iterator`.

2 All requirements on container iterators (23.2.2.2) apply to `optional::iterator`.

```
constexpr auto begin() const noexcept;
```

3 *Constraints*: `T` is an object type other than an array of unknown bound.

4 *Returns*: An object `i` of type `iterator`, such that `i` is an iterator referring to *`*val`* if `has_value()` is `true`, and a past-the-end iterator value otherwise.

```
constexpr auto end() const noexcept;
```

5 *Constraints*: `T` is an object type other than an array of unknown bound.

6 *Returns*: `begin() + has_value()`.

22.5.4.6 Observers [optional.ref.observe]

```
constexpr T* operator->() const noexcept;
```

1 *Hardened preconditions*: `has_value()` is `true`.

2 *Returns*: *`val`*.

```
constexpr T& operator*() const noexcept;
```

3 *Hardened preconditions*: `has_value()` is `true`.

4 *Returns*: *`*val`*.

```
constexpr explicit operator bool() const noexcept;
```

5 *Returns*: *`val`* `!= nullptr`.

```
constexpr bool has_value() const noexcept;
```

6 *Returns*: *`val`* `!= nullptr`.

```
constexpr T& value() const;
```

7 *Effects*: Equivalent to:

```
return has_value() ? *val : throw bad_optional_access();
```

```
template<class U = remove_cv_t<T>> constexpr remove_cv_t<T> value_or(U&& u) const;
```

8 *Constraints*: `T` is a non-array object type.

9 Let `X` be `remove_cv_t<T>`.

10 *Mandates*: `is_constructible_v<X, T&> && is_convertible_v<U, X>` is `true`.

11 *Effects*: Equivalent to:

```
return has_value() ? *val : static_cast<X>(std::forward<U>(u));
```

12 *Remarks*: The return type is unspecified if `T` is an array type or a non-object type.

[*Note 1*: This is to avoid the declaration being ill-formed. — *end note*]

22.5.4.7 Monadic operations [optional.ref.monadic]

```
template<class F> constexpr auto and_then(F&& f) const;
```

1 Let `U` be `invoke_result_t<F, T&>`.

2 *Mandates*: `remove_cvref_t<U>` is a specialization of `optional`.

3 *Effects*: Equivalent to:

```
if (has_value()) {
  return invoke(std::forward<F>(f), *val);
} else {
  return remove_cvref_t<U>();
}
```

```
template<class F>
  constexpr optional<remove_cv_t<invoke_result_t<F, T&>>> transform(F&& f) const;
```

4 Let `U` be `remove_cv_t<invoke_result_t<F, T&>>`.

5 *Mandates*: `U` is a valid contained type for `optional`. The declaration

```
U u(invoke(std::forward<F>(f), *val));
```

is well-formed for some invented variable `u`.

[*Note 1*: There is no requirement that `U` is movable (9.5.1). — *end note*]

6 *Returns*: If `*this` contains a value, an `optional<U>` object whose contained value is direct-non-list-initialized with `invoke(std::forward<F>(f), *val)`; otherwise, `optional<U>()`.

```
template<class F> constexpr optional or_else(F&& f) const;
```

7 *Constraints*: `F` models `invocable`.

8 *Mandates*: `is_same_v<remove_cvref_t<invoke_result_t<F>>, optional>` is `true`.

9 *Effects*: Equivalent to:

```
if (has_value()) {
  return *val;
} else {
  return std::forward<F>(f)();
}
```

22.5.4.8 Modifiers [optional.ref.mod]

```
constexpr void reset() noexcept;
```

1 *Effects*: Assigns `nullptr` to *val*.

2 *Postconditions*: `*this` does not contain a value.

22.5.4.9 Exposition only helper functions [optional.ref.expos]

```
template<class U>
  constexpr void convert-ref-init-val(U&& u);  // exposition only
```

1 *Effects*: Creates a variable `r` as if by `T& r(std::forward<U>(u));` and then initializes *val* with `addressof(r)`.

22.5.5 No-value state indicator [optional.nullopt]

```
struct nullopt_t{see below};
inline constexpr nullopt_t nullopt(unspecified);
```

1 The struct `nullopt_t` is an empty class type used as a unique type to indicate the state of not containing a value for `optional` objects. In particular, `optional<T>` has a constructor with `nullopt_t` as a single argument; this indicates that an optional object not containing a value shall be constructed.

2 Type `nullopt_t` does not have a default constructor or an initializer-list constructor, and is not an aggregate. `nullopt_t` models `copyable` and `three_way_comparable<strong_ordering>`.

22.5.6 Class `bad_optional_access` [optional.bad.access]

```
namespace std {
  class bad_optional_access : public exception {
  public:
    // see 17.9.3 for the specification of the special member functions
    constexpr const char* what() const noexcept override;
  };
}
```

1 The class `bad_optional_access` defines the type of objects thrown as exceptions to report the situation where an attempt is made to access the value of an optional object that does not contain a value.

```
constexpr const char* what() const noexcept override;
```

2 *Returns*: An implementation-defined NTBS, which during constant evaluation is encoded with the ordinary literal encoding (5.13.3).

22.5.7 Relational operators [optional.relops]

```
template<class T, class U> constexpr bool operator==(const optional<T>& x, const optional<U>& y);
```

1 *Constraints*: The expression `*x == *y` is well-formed and its result is convertible to `bool`.

[*Note 1*: `T` need not be *Cpp17EqualityComparable*. — *end note*]

2 *Returns*: If `x.has_value() != y.has_value()`, `false`; otherwise if `x.has_value() == false`, `true`; otherwise `*x == *y`.

3 *Remarks*: Specializations of this function template for which `*x == *y` is a core constant expression are constexpr functions.

```
template<class T, class U> constexpr bool operator!=(const optional<T>& x, const optional<U>& y);
```

4 *Constraints*: The expression `*x != *y` is well-formed and its result is convertible to `bool`.

5 *Returns*: If `x.has_value() != y.has_value()`, `true`; otherwise, if `x.has_value() == false`, `false`; otherwise `*x != *y`.

6 *Remarks*: Specializations of this function template for which `*x != *y` is a core constant expression are constexpr functions.

```
template<class T, class U> constexpr bool operator<(const optional<T>& x, const optional<U>& y);
```

7 *Constraints*: `*x < *y` is well-formed and its result is convertible to `bool`.

8 *Returns*: If `!y`, `false`; otherwise, if `!x`, `true`; otherwise `*x < *y`.

9 *Remarks*: Specializations of this function template for which `*x < *y` is a core constant expression are constexpr functions.

```
template<class T, class U> constexpr bool operator>(const optional<T>& x, const optional<U>& y);
```

10 *Constraints*: The expression `*x > *y` is well-formed and its result is convertible to `bool`.

11 *Returns*: If `!x`, `false`; otherwise, if `!y`, `true`; otherwise `*x > *y`.

12 *Remarks*: Specializations of this function template for which `*x > *y` is a core constant expression are constexpr functions.

```
template<class T, class U> constexpr bool operator<=(const optional<T>& x, const optional<U>& y);
```

13 *Constraints*: The expression `*x <= *y` is well-formed and its result is convertible to `bool`.

14 *Returns*: If `!x`, `true`; otherwise, if `!y`, `false`; otherwise `*x <= *y`.

15 *Remarks*: Specializations of this function template for which `*x <= *y` is a core constant expression are constexpr functions.

```
template<class T, class U> constexpr bool operator>=(const optional<T>& x, const optional<U>& y);
```

16 *Constraints*: The expression `*x >= *y` is well-formed and its result is convertible to `bool`.

17 *Returns*: If `!y`, `true`; otherwise, if `!x`, `false`; otherwise `*x >= *y`.

18 *Remarks*: Specializations of this function template for which `*x >= *y` is a core constant expression are constexpr functions.

```
template<class T, three_way_comparable_with<T> U>
  constexpr compare_three_way_result_t<T, U>
    operator<=>(const optional<T>& x, const optional<U>& y);
```

19 *Returns*: If `x && y`, `*x <=> *y`; otherwise `x.has_value() <=> y.has_value()`.

20 *Remarks*: Specializations of this function template for which `*x <=> *y` is a core constant expression are constexpr functions.

22.5.8 Comparison with `nullopt` [optional.nullops]

```
template<class T> constexpr bool operator==(const optional<T>& x, nullopt_t) noexcept;
```

1 *Returns*: `!x`.

```
template<class T> constexpr strong_ordering operator<=>(const optional<T>& x, nullopt_t) noexcept;
```

2 *Returns*: `x.has_value() <=> false`.

22.5.9 Comparison with `T` [optional.comp.with.t]

```
template<class T, class U> constexpr bool operator==(const optional<T>& x, const U& v);
```

1 *Constraints*: `U` is not a specialization of `optional`. The expression `*x == v` is well-formed and its result is convertible to `bool`.

[*Note 1*: `T` need not be *Cpp17EqualityComparable*. — *end note*]

2 *Effects*: Equivalent to:

```
if (x.has_value())
  return *x == v;
return false;
```

```
template<class T, class U> constexpr bool operator==(const T& v, const optional<U>& x);
```

3 *Constraints*: `T` is not a specialization of `optional`. The expression `v == *x` is well-formed and its result is convertible to `bool`.

4 *Effects*: Equivalent to:

```
if (x.has_value())
  return v == *x;
return false;
```

```
template<class T, class U> constexpr bool operator!=(const optional<T>& x, const U& v);
```

5 *Constraints*: `U` is not a specialization of `optional`. The expression `*x != v` is well-formed and its result is convertible to `bool`.

6 *Effects*: Equivalent to:

```
if (x.has_value())
  return *x != v;
return true;
```

```
template<class T, class U> constexpr bool operator!=(const T& v, const optional<U>& x);
```

7 *Constraints*: `T` is not a specialization of `optional`. The expression `v != *x` is well-formed and its result is convertible to `bool`.

8 *Effects*: Equivalent to:

```
if (x.has_value())
  return v != *x;
return true;
```

```
template<class T, class U> constexpr bool operator<(const optional<T>& x, const U& v);
```

9 *Constraints*: `U` is not a specialization of `optional`. The expression `*x < v` is well-formed and its result is convertible to `bool`.

10 *Effects*: Equivalent to:

```
if (x.has_value())
  return *x < v;
return true;
```

```
template<class T, class U> constexpr bool operator<(const T& v, const optional<U>& x);
```

11 *Constraints*: `T` is not a specialization of `optional`. The expression `v < *x` is well-formed and its result is convertible to `bool`.

12 *Effects*: Equivalent to:

```
if (x.has_value())
  return v < *x;
return false;
```

```
template<class T, class U> constexpr bool operator>(const optional<T>& x, const U& v);
```

13 *Constraints*: `U` is not a specialization of `optional`. The expression `*x > v` is well-formed and its result is convertible to `bool`.

14 *Effects*: Equivalent to:

```
if (x.has_value())
  return *x > v;
return false;
```

```
template<class T, class U> constexpr bool operator>(const T& v, const optional<U>& x);
```

15 *Constraints*: `T` is not a specialization of `optional`. The expression `v > *x` is well-formed and its result is convertible to `bool`.

16 *Effects*: Equivalent to:

```
if (x.has_value())
  return v > *x;
return true;
```

```
template<class T, class U> constexpr bool operator<=(const optional<T>& x, const U& v);
```

17 *Constraints*: `U` is not a specialization of `optional`. The expression `*x <= v` is well-formed and its result is convertible to `bool`.

18 *Effects*: Equivalent to:

```
if (x.has_value())
  return *x <= v;
return true;
```

```
template<class T, class U> constexpr bool operator<=(const T& v, const optional<U>& x);
```

19 *Constraints*: `T` is not a specialization of `optional`. The expression `v <= *x` is well-formed and its result is convertible to `bool`.

20 *Effects*: Equivalent to:

```
if (x.has_value())
  return v <= *x;
return false;
```

```
template<class T, class U> constexpr bool operator>=(const optional<T>& x, const U& v);
```

21 *Constraints*: `U` is not a specialization of `optional`. The expression `*x >= v` is well-formed and its result is convertible to `bool`.

22 *Effects*: Equivalent to:

```
if (x.has_value())
  return *x >= v;
return false;
```

```
template<class T, class U> constexpr bool operator>=(const T& v, const optional<U>& x);
```

23 *Constraints*: `T` is not a specialization of `optional`. The expression `v >= *x` is well-formed and its result is convertible to `bool`.

24 *Effects*: Equivalent to:

```
if (x.has_value())
  return v >= *x;
return true;
```

```
template<class T, class U>
  requires (!is-derived-from-optional<U>) && three_way_comparable_with<T, U>
  constexpr compare_three_way_result_t<T, U>
    operator<=>(const optional<T>& x, const U& v);
```

25 *Effects*: Equivalent to: `return x.has_value() ? *x <=> v : strong_ordering::less;`

22.5.10 Specialized algorithms [optional.specalg]

```
template<class T>
  constexpr void swap(optional<T>& x, optional<T>& y) noexcept(noexcept(x.swap(y)));
```

1 *Constraints*:

```
is_reference_v<T> || (is_move_constructible_v<T> && is_swappable_v<T>)
```

is `true`.

2 *Effects*: Calls `x.swap(y)`.

```
template<class T> constexpr optional<decay_t<T>> make_optional(T&& v);
```

3 *Constraints*: The call to `make_optional` does not use an explicit *template-argument-list* that begins with a type *template-argument*.

4 *Effects*: Equivalent to: `return optional<decay_t<T>>(std::forward<T>(v));`

```
template<class T, class...Args>
  constexpr optional<T> make_optional(Args&&... args);
```

5 *Effects*: Equivalent to: `return optional<T>(in_place, std::forward<Args>(args)...);`

```
template<class T, class U, class... Args>
  constexpr optional<T> make_optional(initializer_list<U> il, Args&&... args);
```

6 *Effects*: Equivalent to: `return optional<T>(in_place, il, std::forward<Args>(args)...);`

22.5.11 Hash support [optional.hash]

```
template<class T> struct hash<optional<T>>;
```

1 The specialization `hash<optional<T>>` is enabled (22.10.19) if and only if `hash<remove_const_t<T>>` is enabled. When enabled, for an object `o` of type `optional<T>`, if `o.has_value() == true`, then `hash<optional<T>>()(o)` evaluates to the same value as `hash<remove_const_t<T>>()(*o)`; otherwise it evaluates to an unspecified value. The member functions are not guaranteed to be `noexcept`.

22.6 Variants [variant]

22.6.1 General [variant.general]

1 A variant object holds and manages the lifetime of a value. If the `variant` holds a value, that value's type has to be one of the template argument types given to `variant`. These template arguments are called alternatives.

2 In 22.6, *GET* denotes a set of exposition-only function templates (22.6.5).

22.6.2 Header <variant> synopsis [variant.syn]

```
// mostly freestanding
#include <compare>              // see 17.12.1

namespace std {
  // 22.6.3, class template variant
  template<class... Types>
    class variant;

  // 22.6.4, variant helper classes
  template<class T> struct variant_size;                          // not defined
  template<class T> struct variant_size<const T>;
  template<class T>
    constexpr size_t variant_size_v = variant_size<T>::value;

  template<class... Types>
    struct variant_size<variant<Types...>>;

  template<size_t I, class T> struct variant_alternative;         // not defined
  template<size_t I, class T> struct variant_alternative<I, const T>;
  template<size_t I, class T>
    using variant_alternative_t = variant_alternative<I, T>::type;

  template<size_t I, class... Types>
    struct variant_alternative<I, variant<Types...>>;

  inline constexpr size_t variant_npos = -1;

  // 22.6.5, value access
  template<class T, class... Types>
    constexpr bool holds_alternative(const variant<Types...>&) noexcept;

  template<size_t I, class... Types>
    constexpr variant_alternative_t<I, variant<Types...>>&
      get(variant<Types...>&);                                    // freestanding-deleted
  template<size_t I, class... Types>
    constexpr variant_alternative_t<I, variant<Types...>>&&

  template<> struct hash<monostate>;
}
```

22.6.3 Class template variant [variant.variant]

22.6.3.1 General [variant.variant.general]

```
namespace std {
  template<class... Types>
  class variant {
  public:
```

```
    // 22.6.3.2, constructors
    constexpr variant() noexcept(see below);
    constexpr variant(const variant&) noexcept(see below);
    constexpr variant(variant&&) noexcept(see below);

    template<class T>
      constexpr variant(T&&) noexcept(see below);

    template<class T, class... Args>
      constexpr explicit variant(in_place_type_t<T>, Args&&...);
    template<class T, class U, class... Args>
      constexpr explicit variant(in_place_type_t<T>, initializer_list<U>, Args&&...);

    template<size_t I, class... Args>
      constexpr explicit variant(in_place_index_t<I>, Args&&...);
    template<size_t I, class U, class... Args>
      constexpr explicit variant(in_place_index_t<I>, initializer_list<U>, Args&&...);

    // 22.6.3.3, destructor
    constexpr ~variant();

    // 22.6.3.4, assignment
    constexpr variant& operator=(const variant&);
    constexpr variant& operator=(variant&&) noexcept(see below);

    template<class T> constexpr variant& operator=(T&&) noexcept(see below);

    // 22.6.3.5, modifiers
    template<class T, class... Args>
      constexpr T& emplace(Args&&...);
    template<class T, class U, class... Args>
      constexpr T& emplace(initializer_list<U>, Args&&...);
    template<size_t I, class... Args>
      constexpr variant_alternative_t<I, variant<Types...>>& emplace(Args&&...);
    template<size_t I, class U, class... Args>
      constexpr variant_alternative_t<I, variant<Types...>>&
        emplace(initializer_list<U>, Args&&...);

    // 22.6.3.6, value status
    constexpr bool valueless_by_exception() const noexcept;
    constexpr size_t index() const noexcept;

    // 22.6.3.7, swap
    constexpr void swap(variant&) noexcept(see below);

    // 22.6.7, visitation
    template<class Self, class Visitor>
      constexpr decltype(auto) visit(this Self&&, Visitor&&);
    template<class R, class Self, class Visitor>
      constexpr R visit(this Self&&, Visitor&&);
  };
}
```

1 Any instance of `variant` at any given time either holds a value of one of its alternative types or holds no value. When an instance of `variant` holds a value of alternative type `T`, it means that a value of type `T`, referred to as the `variant` object's *contained value*, is nested within (6.8.2) the `variant` object.

2 All types in `Types` shall meet the *Cpp17Destructible* requirements (Table 35).

3 A program that instantiates the definition of `variant` with no template arguments is ill-formed.

4 If a program declares an explicit or partial specialization of `variant`, the program is ill-formed, no diagnostic required.

22.6.3.2 Constructors [variant.ctor]

1 In the descriptions that follow, let i be in the range $[0, \texttt{sizeof...(Types)})$, and $\texttt{T}_i$ be the i^{th} type in `Types`.

```
constexpr variant() noexcept(see below);
```

2 *Constraints*: `is_default_constructible_v<T0>` is `true`.

3 *Effects*: Constructs a `variant` holding a value-initialized value of type $\texttt{T}_0$.

4 *Postconditions*: `valueless_by_exception()` is `false` and `index()` is `0`.

5 *Throws*: Any exception thrown by the value-initialization of $\texttt{T}_0$.

6 *Remarks*: This function is `constexpr` if and only if the value-initialization of the alternative type $\texttt{T}_0$ would be constexpr-suitable (9.2.6). The exception specification is equivalent to `is_nothrow_default_constructible_v<T0>`.

[*Note 1*: See also class `monostate`. — *end note*]

```
constexpr variant(const variant& w) noexcept(see below);
```

7 *Effects*: If `w` holds a value, initializes the `variant` to hold the same alternative as `w` and direct-initializes the contained value with *GET*`<j>(w)`, where `j` is `w.index()`. Otherwise, initializes the `variant` to not hold a value.

8 *Throws*: Any exception thrown by the initialization of the contained value.

9 *Remarks*: This constructor is defined as deleted unless `is_copy_constructible_v<Ti>` is `true` for all i. If `is_trivially_copy_constructible_v<Ti>` is `true` for all i, this constructor is trivial. The exception specification is equivalent to the logical AND of `is_nothrow_copy_constructible_v<Ti>` for all i.

```
constexpr variant(variant&& w) noexcept(see below);
```

10 *Constraints*: `is_move_constructible_v<Ti>` is `true` for all i.

11 *Effects*: If `w` holds a value, initializes the `variant` to hold the same alternative as `w` and direct-initializes the contained value with *GET*`<j>(std::move(w))`, where `j` is `w.index()`. Otherwise, initializes the `variant` to not hold a value.

12 *Throws*: Any exception thrown by the initialization of the contained value.

13 *Remarks*: The exception specification is equivalent to the logical AND of `is_nothrow_move_constructible_v<Ti>` for all i. If `is_trivially_move_constructible_v<Ti>` is `true` for all i, this constructor is trivial.

```
template<class T> constexpr variant(T&& t) noexcept(see below);
```

14 Let $\texttt{T}_j$ be a type that is determined as follows: build an imaginary function *FUN*$(\texttt{T}_i)$ for each alternative type $\texttt{T}_i$ for which $\texttt{T}_i$ `x[] = {std::forward<T>(t)};` is well-formed for some invented variable `x`. The overload *FUN*$(\texttt{T}_j)$ selected by overload resolution for the expression *FUN*`(std::forward<T>(t))` defines the alternative $\texttt{T}_j$ which is the type of the contained value after construction.

15 *Constraints*:

(15.1) — `sizeof...(Types)` is nonzero,

(15.2) — `is_same_v<remove_cvref_t<T>, variant>` is `false`,

(15.3) — `remove_cvref_t<T>` is neither a specialization of `in_place_type_t` nor a specialization of `in_place_index_t`,

(15.4) — `is_constructible_v<`$\texttt{T}_j$`, T>` is `true`, and

(15.5) — the expression *FUN*`(std::forward<T>(t))` (with *FUN* being the above-mentioned set of imaginary functions) is well-formed.

[*Note 2*:

```
variant<string, string> v("abc");
```

is ill-formed, as both alternative types have an equally viable constructor for the argument. — *end note*]

16 *Effects*: Initializes `*this` to hold the alternative type $\texttt{T}_j$ and direct-non-list-initializes the contained value with `std::forward<T>(t)`.

17 *Postconditions*: `holds_alternative<`T_j`>(*this)` is `true`.

18 *Throws*: Any exception thrown by the initialization of the contained value.

19 *Remarks*: The exception specification is equivalent to `is_nothrow_constructible_v<`T_j`, T>`. If T_j's selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

```
template<class T, class... Args> constexpr explicit variant(in_place_type_t<T>, Args&&... args);
```

20 *Constraints*:

(20.1) — There is exactly one occurrence of `T` in `Types...` and

(20.2) — `is_constructible_v<T, Args...>` is `true`.

21 *Effects*: Direct-non-list-initializes the contained value of type `T` with `std::forward<Args>(args)...`.

22 *Postconditions*: `holds_alternative<T>(*this)` is `true`.

23 *Throws*: Any exception thrown by the initialization of the contained value.

24 *Remarks*: If `T`'s selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

```
template<class T, class U, class... Args>
  constexpr explicit variant(in_place_type_t<T>, initializer_list<U> il, Args&&... args);
```

25 *Constraints*:

(25.1) — There is exactly one occurrence of `T` in `Types...` and

(25.2) — `is_constructible_v<T, initializer_list<U>&, Args...>` is `true`.

26 *Effects*: Direct-non-list-initializes the contained value of type `T` with `il, std::forward<Args>(args)...`.

27 *Postconditions*: `holds_alternative<T>(*this)` is `true`.

28 *Throws*: Any exception thrown by the initialization of the contained value.

29 *Remarks*: If `T`'s selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

```
template<size_t I, class... Args> constexpr explicit variant(in_place_index_t<I>, Args&&... args);
```

30 *Constraints*:

(30.1) — `I` is less than `sizeof...(Types)` and

(30.2) — `is_constructible_v<`T_I`, Args...>` is `true`.

31 *Effects*: Direct-non-list-initializes the contained value of type T_I with `std::forward<Args>(args)...`.

32 *Postconditions*: `index()` is `I`.

33 *Throws*: Any exception thrown by the initialization of the contained value.

34 *Remarks*: If T_I's selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

```
template<size_t I, class U, class... Args>
  constexpr explicit variant(in_place_index_t<I>, initializer_list<U> il, Args&&... args);
```

35 *Constraints*:

(35.1) — `I` is less than `sizeof...(Types)` and

(35.2) — `is_constructible_v<`T_I`, initializer_list<U>&, Args...>` is `true`.

36 *Effects*: Direct-non-list-initializes the contained value of type T_I with `il, std::forward<Args>(args)...`.

37 *Postconditions*: `index()` is `I`.

38 *Throws*: Any exception thrown by the initialization of the contained value.

39 *Remarks*: If T_I's selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

22.6.3.3 Destructor [variant.dtor]

```
constexpr ~variant();
```

1 *Effects*: If `valueless_by_exception()` is `false`, destroys the currently contained value.

2 *Remarks*: If `is_trivially_destructible_v<`$\texttt{T}_i$`>` is `true` for all $\texttt{T}_i$, then this destructor is trivial.

22.6.3.4 Assignment [variant.assign]

```
constexpr variant& operator=(const variant& rhs);
```

1 Let j be `rhs.index()`.

2 *Effects*:

(2.1) — If neither `*this` nor `rhs` holds a value, there is no effect.

(2.2) — Otherwise, if `*this` holds a value but `rhs` does not, destroys the value contained in `*this` and sets `*this` to not hold a value.

(2.3) — Otherwise, if `index() ==` j, assigns the value contained in `rhs` to the value contained in `*this`.

(2.4) — Otherwise, if either `is_nothrow_copy_constructible_v<`$\texttt{T}_j$`>` is `true` or `is_nothrow_move_constructible_v<`$\texttt{T}_j$`>` is `false`, equivalent to `emplace<`j`>(`*GET*`<`j`>(rhs))`.

(2.5) — Otherwise, equivalent to `operator=(variant(rhs))`.

3 *Postconditions*: `index() == rhs.index()`.

4 *Returns*: `*this`.

5 *Remarks*: This operator is defined as deleted unless `is_copy_constructible_v<`$\texttt{T}_i$`> && is_copy_assignable_v<`$\texttt{T}_i$`>` is `true` for all i. If `is_trivially_copy_constructible_v<`$\texttt{T}_i$`> && is_trivially_copy_assignable_v<`$\texttt{T}_i$`> && is_trivially_destructible_v<`$\texttt{T}_i$`>` is `true` for all i, this assignment operator is trivial.

```
constexpr variant& operator=(variant&& rhs) noexcept(see below);
```

6 Let j be `rhs.index()`.

7 *Constraints*: `is_move_constructible_v<`$\texttt{T}_i$`> && is_move_assignable_v<`$\texttt{T}_i$`>` is `true` for all i.

8 *Effects*:

(8.1) — If neither `*this` nor `rhs` holds a value, there is no effect.

(8.2) — Otherwise, if `*this` holds a value but `rhs` does not, destroys the value contained in `*this` and sets `*this` to not hold a value.

(8.3) — Otherwise, if `index() ==` j, assigns *GET*`<`j`>(std::move(rhs))` to the value contained in `*this`.

(8.4) — Otherwise, equivalent to `emplace<`j`>(`*GET*`<`j`>(std::move(rhs)))`.

9 *Returns*: `*this`.

10 *Remarks*: If `is_trivially_move_constructible_v<`$\texttt{T}_i$`> && is_trivially_move_assignable_v<`$\texttt{T}_i$`> && is_trivially_destructible_v<`$\texttt{T}_i$`>` is `true` for all i, this assignment operator is trivial. The exception specification is equivalent to `is_nothrow_move_constructible_v<`$\texttt{T}_i$`> && is_nothrow_move_assignable_v<`$\texttt{T}_i$`>` for all i.

(10.1) — If an exception is thrown during the call to $\texttt{T}_j$'s move construction (with j being `rhs.index()`), the `variant` will hold no value.

(10.2) — If an exception is thrown during the call to $\texttt{T}_j$'s move assignment, the state of the contained value is as defined by the exception safety guarantee of $\texttt{T}_j$'s move assignment; `index()` will be j.

```
template<class T> constexpr variant& operator=(T&& t) noexcept(see below);
```

11 Let $\texttt{T}_j$ be a type that is determined as follows: build an imaginary function *FUN*$(\texttt{T}_i)$ for each alternative type $\texttt{T}_i$ for which $\texttt{T}_i$ `x[] = {std::forward<T>(t)};` is well-formed for some invented variable `x`. The overload *FUN*$(\texttt{T}_j)$ selected by overload resolution for the expression *FUN*`(std::forward<T>(t))` defines the alternative $\texttt{T}_j$ which is the type of the contained value after assignment.

12 *Constraints*:

(12.1) — `is_same_v<remove_cvref_t<T>, variant>` is `false`,

(12.2) — `is_assignable_v<T_j&, T> && is_constructible_v<T_j, T>` is `true`, and

(12.3) — the expression *FUN*`(std::forward<T>(t))` (with *FUN* being the above-mentioned set of imaginary functions) is well-formed.

[*Note 1*:

```
variant<string, string> v;
v = "abc";
```

is ill-formed, as both alternative types have an equally viable constructor for the argument. — *end note*]

13 *Effects*:

(13.1) — If `*this` holds a T_j, assigns `std::forward<T>(t)` to the value contained in `*this`.

(13.2) — Otherwise, if `is_nothrow_constructible_v<T_j, T> || !is_nothrow_move_constructible_v<T_j>` is `true`, equivalent to `emplace<`*j*`>(std::forward<T>(t))`.

(13.3) — Otherwise, equivalent to `emplace<`*j*`>(T_j(std::forward<T>(t)))`.

14 *Postconditions*: `holds_alternative<T_j>(*this)` is `true`, with T_j selected by the imaginary function overload resolution described above.

15 *Returns*: `*this`.

16 *Remarks*: The exception specification is equivalent to:

```
is_nothrow_assignable_v<T_j&, T> && is_nothrow_constructible_v<T_j, T>
```

(16.1) — If an exception is thrown during the assignment of `std::forward<T>(t)` to the value contained in `*this`, the state of the contained value and `t` are as defined by the exception safety guarantee of the assignment expression; `valueless_by_exception()` will be `false`.

(16.2) — If an exception is thrown during the initialization of the contained value, the `variant` object is permitted to not hold a value.

22.6.3.5 Modifiers [variant.mod]

```
template<class T, class... Args> constexpr T& emplace(Args&&... args);
```

1 *Constraints*: `is_constructible_v<T, Args...>` is `true`, and `T` occurs exactly once in `Types`.

2 *Effects*: Equivalent to:

```
return emplace<I>(std::forward<Args>(args)...);
```

where I is the zero-based index of `T` in `Types`.

```
template<class T, class U, class... Args>
  constexpr T& emplace(initializer_list<U> il, Args&&... args);
```

3 *Constraints*: `is_constructible_v<T, initializer_list<U>&, Args...>` is `true`, and `T` occurs exactly once in `Types`.

4 *Effects*: Equivalent to:

```
return emplace<I>(il, std::forward<Args>(args)...);
```

where I is the zero-based index of `T` in `Types`.

```
template<size_t I, class... Args>
  constexpr variant_alternative_t<I, variant<Types...>>& emplace(Args&&... args);
```

5 *Mandates*: `I` < `sizeof...(Types)`.

6 *Constraints*: `is_constructible_v<T_I, Args...>` is `true`.

7 *Effects*: Destroys the currently contained value if `valueless_by_exception()` is `false`. Then direct-non-list-initializes the contained value of type T_I with the arguments `std::forward<Args>(args)...`.

8 *Postconditions*: `index()` is `I`.

9 *Returns*: A reference to the new contained value.

10 *Throws*: Any exception thrown during the initialization of the contained value.

11 *Remarks*: If an exception is thrown during the initialization of the contained value, the `variant` is permitted to not hold a value.

```
template<size_t I, class U, class... Args>
  constexpr variant_alternative_t<I, variant<Types...>>&
    emplace(initializer_list<U> il, Args&&... args);
```

12 *Mandates*: `I` < `sizeof...(Types)`.

13 *Constraints*: `is_constructible_v<`T_I`, initializer_list<U>&, Args...>` is `true`.

14 *Effects*: Destroys the currently contained value if `valueless_by_exception()` is `false`. Then direct-non-list-initializes the contained value of type T_I with `il, std::forward<Args>(args)...`.

15 *Postconditions*: `index()` is `I`.

16 *Returns*: A reference to the new contained value.

17 *Throws*: Any exception thrown during the initialization of the contained value.

18 *Remarks*: If an exception is thrown during the initialization of the contained value, the `variant` is permitted to not hold a value.

22.6.3.6 Value status [variant.status]

```
constexpr bool valueless_by_exception() const noexcept;
```

1 *Effects*: Returns `false` if and only if the `variant` holds a value.

2 [*Note 1*: It is possible for a `variant` to hold no value if an exception is thrown during a type-changing assignment or emplacement. The latter means that even a `variant<float, int>` can become `valueless_by_exception()`, for instance by

```
struct S { operator int() { throw 42; }};
variant<float, int> v{12.f};
v.emplace<1>(S());
```

— *end note*]

```
constexpr size_t index() const noexcept;
```

3 *Effects*: If `valueless_by_exception()` is `true`, returns `variant_npos`. Otherwise, returns the zero-based index of the alternative of the contained value.

22.6.3.7 Swap [variant.swap]

```
constexpr void swap(variant& rhs) noexcept(see below);
```

1 *Mandates*: `is_move_constructible_v<`T_i`>` is `true` for all i.

2 *Preconditions*: Each T_i meets the *Cpp17Swappable* requirements (16.4.4.3).

3 *Effects*:

(3.1) — If `valueless_by_exception() && rhs.valueless_by_exception()` no effect.

(3.2) — Otherwise, if `index() == rhs.index()`, calls `swap(`*GET*`<`*i*`>(*this), `*GET*`<`*i*`>(rhs))` where i is `index()`.

(3.3) — Otherwise, exchanges values of `rhs` and `*this`.

4 *Throws*: If `index() == rhs.index()`, any exception thrown by `swap(`*GET*`<`*i*`>(*this), `*GET*`<`*i*`>(rhs))` with i being `index()`. Otherwise, any exception thrown by the move constructor of T_i or T_j with i being `index()` and j being `rhs.index()`.

5 *Remarks*: If an exception is thrown during the call to function `swap(`*GET*`<`*i*`>(*this), `*GET*`<`*i*`>(rhs))`, the states of the contained values of `*this` and of `rhs` are determined by the exception safety guarantee of `swap` for lvalues of T_i with i being `index()`. If an exception is thrown during the exchange of the values of `*this` and `rhs`, the states of the values of `*this` and of `rhs` are determined by the exception safety guarantee of `variant`'s move constructor. The exception specification is equivalent to the logical AND of `is_nothrow_move_constructible_v<`T_i`> && is_nothrow_swappable_v<`T_i`>` for all i.

22.6.4 `variant` helper classes [variant.helper]

```
template<class T> struct variant_size;
```

1 All specializations of `variant_size` meet the *Cpp17UnaryTypeTrait* requirements (21.3.2) with a base characteristic of `integral_constant<size_t, N>` for some `N`.

```
template<class T> struct variant_size<const T>;
```

2 Let `VS` denote `variant_size<T>` of the cv-unqualified type `T`. Then each specialization of the template meets the *Cpp17UnaryTypeTrait* requirements (21.3.2) with a base characteristic of `integral_constant<size_t, VS::value>`.

```
template<class... Types>
  struct variant_size<variant<Types...>> : integral_constant<size_t, sizeof...(Types)> { };

template<size_t I, class T> struct variant_alternative<I, const T>;
```

3 Let `VA` denote `variant_alternative<I, T>` of the cv-unqualified type `T`. Then each specialization of the template meets the *Cpp17TransformationTrait* requirements (21.3.2) with a member typedef `type` that names the type `const VA::type`.

```
variant_alternative<I, variant<Types...>>::type
```

4 *Mandates*: `I` $<$ `sizeof...(Types)`.

5 *Result*: The type $\texttt{T}_I$.

22.6.5 Value access [variant.get]

```
template<class T, class... Types>
  constexpr bool holds_alternative(const variant<Types...>& v) noexcept;
```

1 *Mandates*: The type `T` occurs exactly once in `Types`.

2 *Returns*: `true` if `index()` is equal to the zero-based index of `T` in `Types`.

```
template<size_t I, class... Types>
  constexpr variant_alternative_t<I, variant<Types...>>&
    GET(variant<Types...>& v);                                  // exposition only
template<size_t I, class... Types>
  constexpr variant_alternative_t<I, variant<Types...>>&&
    GET(variant<Types...>&& v);                                 // exposition only
template<size_t I, class... Types>
  constexpr const variant_alternative_t<I, variant<Types...>>&
    GET(const variant<Types...>& v);                            // exposition only
template<size_t I, class... Types>
  constexpr const variant_alternative_t<I, variant<Types...>>&&
    GET(const variant<Types...>&& v);                           // exposition only
```

3 *Mandates*: `I` $<$ `sizeof...(Types)`.

4 *Preconditions*: `v.index()` is `I`.

5 *Returns*: A reference to the object stored in the `variant`.

```
template<size_t I, class... Types>
  constexpr variant_alternative_t<I, variant<Types...>>& get(variant<Types...>& v);
template<size_t I, class... Types>
  constexpr variant_alternative_t<I, variant<Types...>>&& get(variant<Types...>&& v);
template<size_t I, class... Types>
  constexpr const variant_alternative_t<I, variant<Types...>>& get(const variant<Types...>& v);
template<size_t I, class... Types>
  constexpr const variant_alternative_t<I, variant<Types...>>&& get(const variant<Types...>&& v);
```

6 *Mandates*: `I` $<$ `sizeof...(Types)`.

7 *Effects*: If `v.index()` is `I`, returns a reference to the object stored in the `variant`. Otherwise, throws an exception of type `bad_variant_access`.

```
template<class T, class... Types> constexpr T& get(variant<Types...>& v);
template<class T, class... Types> constexpr T&& get(variant<Types...>&& v);
template<class T, class... Types> constexpr const T& get(const variant<Types...>& v);
template<class T, class... Types> constexpr const T&& get(const variant<Types...>&& v);
```

8 *Mandates*: The type `T` occurs exactly once in `Types`.

9 *Effects*: If `v` holds a value of type `T`, returns a reference to that value. Otherwise, throws an exception of type `bad_variant_access`.

```
template<size_t I, class... Types>
  constexpr add_pointer_t<variant_alternative_t<I, variant<Types...>>>
    get_if(variant<Types...>* v) noexcept;
template<size_t I, class... Types>
  constexpr add_pointer_t<const variant_alternative_t<I, variant<Types...>>>
    get_if(const variant<Types...>* v) noexcept;
```

10 *Mandates*: `I` < `sizeof...(Types)`.

11 *Returns*: A pointer to the value stored in the `variant`, if `v != nullptr` and `v->index() == I`. Otherwise, returns `nullptr`.

```
template<class T, class... Types>
  constexpr add_pointer_t<T>
    get_if(variant<Types...>* v) noexcept;
template<class T, class... Types>
  constexpr add_pointer_t<const T>
    get_if(const variant<Types...>* v) noexcept;
```

12 *Mandates*: The type `T` occurs exactly once in `Types`.

13 *Effects*: Equivalent to: `return get_if<`*i*`>(v);` with *i* being the zero-based index of `T` in `Types`.

22.6.6 Relational operators [variant.relops]

```
template<class... Types>
  constexpr bool operator==(const variant<Types...>& v, const variant<Types...>& w);
```

1 *Constraints*: *GET*`<`*i*`>(v) == `*GET*`<`*i*`>(w)` is a valid expression that is convertible to `bool`, for all *i*.

2 *Returns*: If `v.index() != w.index()`, `false`; otherwise if `v.valueless_by_exception()`, `true`; otherwise *GET*`<`*i*`>(v) == `*GET*`<`*i*`>(w)` with *i* being `v.index()`.

```
template<class... Types>
  constexpr bool operator!=(const variant<Types...>& v, const variant<Types...>& w);
```

3 *Constraints*: *GET*`<`*i*`>(v) != `*GET*`<`*i*`>(w)` is a valid expression that is convertible to `bool`, for all *i*.

4 *Returns*: If `v.index() != w.index()`, `true`; otherwise if `v.valueless_by_exception()`, `false`; otherwise *GET*`<`*i*`>(v) != `*GET*`<`*i*`>(w)` with *i* being `v.index()`.

```
template<class... Types>
  constexpr bool operator<(const variant<Types...>& v, const variant<Types...>& w);
```

5 *Constraints*: *GET*`<`*i*`>(v) < `*GET*`<`*i*`>(w)` is a valid expression that is convertible to `bool`, for all *i*.

6 *Returns*: If `w.valueless_by_exception()`, `false`; otherwise if `v.valueless_by_exception()`, `true`; otherwise, if `v.index() < w.index()`, `true`; otherwise if `v.index() > w.index()`, `false`; otherwise *GET*`<`*i*`>(v) < `*GET*`<`*i*`>(w)` with *i* being `v.index()`.

```
template<class... Types>
  constexpr bool operator>(const variant<Types...>& v, const variant<Types...>& w);
```

7 *Constraints*: *GET*`<`*i*`>(v) > `*GET*`<`*i*`>(w)` is a valid expression that is convertible to `bool`, for all *i*.

8 *Returns*: If `v.valueless_by_exception()`, `false`; otherwise if `w.valueless_by_exception()`, `true`; otherwise, if `v.index() > w.index()`, `true`; otherwise if `v.index() < w.index()`, `false`; otherwise *GET*`<`*i*`>(v) > `*GET*`<`*i*`>(w)` with *i* being `v.index()`.

```
template<class... Types>
  constexpr bool operator<=(const variant<Types...>& v, const variant<Types...>& w);
```

9 *Constraints*: *GET*`<`*i*`>(v) <= `*GET*`<`*i*`>(w)` is a valid expression that is convertible to `bool`, for all *i*.

10 *Returns*: If `v.valueless_by_exception()`, `true`; otherwise if `w.valueless_by_exception()`, `false`; otherwise, if `v.index() < w.index()`, `true`; otherwise if `v.index() > w.index()`, `false`; otherwise *GET*`<`*i*`>(v) <= `*GET*`<`*i*`>(w)` with *i* being `v.index()`.

```
template<class... Types>
  constexpr bool operator>=(const variant<Types...>& v, const variant<Types...>& w);
```

11 *Constraints*: *GET*`<`*i*`>(v) >= `*GET*`<`*i*`>(w)` is a valid expression that is convertible to `bool`, for all *i*.

12 *Returns*: If `w.valueless_by_exception()`, `true`; otherwise if `v.valueless_by_exception()`, `false`; otherwise, if `v.index() > w.index()`, `true`; otherwise if `v.index() < w.index()`, `false`; otherwise *GET*`<`*i*`>(v) >= `*GET*`<`*i*`>(w)` with *i* being `v.index()`.

```
template<class... Types> requires (three_way_comparable<Types> && ...)
  constexpr common_comparison_category_t<compare_three_way_result_t<Types>...>
    operator<=>(const variant<Types...>& v, const variant<Types...>& w);
```

13 *Effects*: Equivalent to:

```
if (v.valueless_by_exception() && w.valueless_by_exception())
  return strong_ordering::equal;
if (v.valueless_by_exception()) return strong_ordering::less;
if (w.valueless_by_exception()) return strong_ordering::greater;
if (auto c = v.index() <=> w.index(); c != 0) return c;
return GET<i>(v) <=> GET<i>(w);
```

with *i* being `v.index()`.

22.6.7 Visitation [variant.visit]

```
template<class Visitor, class... Variants>
  constexpr see below visit(Visitor&& vis, Variants&&... vars);
template<class R, class Visitor, class... Variants>
  constexpr R visit(Visitor&& vis, Variants&&... vars);
```

1 Let *as-variant* denote the following exposition-only function templates:

```
template<class... Ts>
  constexpr auto&& as-variant(variant<Ts...>& var) { return var; }
template<class... Ts>
  constexpr auto&& as-variant(const variant<Ts...>& var) { return var; }
template<class... Ts>
  constexpr auto&& as-variant(variant<Ts...>&& var) { return std::move(var); }
template<class... Ts>
  constexpr auto&& as-variant(const variant<Ts...>&& var) { return std::move(var); }
```

Let n be `sizeof...(Variants)`. For each $0 \le i < n$, let $\texttt{V}_i$ denote the type `decltype(`*as-variant*`(std::forward<Variants`$_i$`>(vars`$_i$`)))`.

2 *Constraints*: $\texttt{V}_i$ is a valid type for all $0 \le i < n$.

3 Let `V` denote the pack of types $\texttt{V}_i$.

4 Let m be a pack of n values of type `size_t`. Such a pack is valid if $0 \le m_i <$ `variant_size_v<remove_reference_t<V`$_i$`>>` for all $0 \le i < n$. For each valid pack m, let $e(m)$ denote the expression:

```
INVOKE(std::forward<Visitor>(vis), GET<m>(std::forward<V>(vars))...)  // see 22.10.4
```

for the first form and

```
INVOKE<R>(std::forward<Visitor>(vis), GET<m>(std::forward<V>(vars))...)  // see 22.10.4
```

for the second form.

5 *Mandates*: For each valid pack m, $e(m)$ is a valid expression. All such expressions are of the same type and value category.

6 *Returns*: $e(m)$, where m is the pack for which m_i is *as-variant*`(vars`$_i$`).index()` for all $0 \le i < n$. The return type is `decltype(`$e(m)$`)` for the first form.

7 *Throws*: `bad_variant_access` if `(`*as-variant*`(vars).valueless_by_exception() || ...)` is `true`.

8 *Complexity*: For $n \le 1$, the invocation of the callable object is implemented in constant time, i.e., for $n = 1$, it does not depend on the number of alternative types of $\texttt{V}_0$. For $n > 1$, the invocation of the callable object has no complexity requirements.

```
template<class Self, class Visitor>
  constexpr decltype(auto) visit(this Self&& self, Visitor&& vis);
```

9 Let `V` be *OVERRIDE_REF*`(Self&&, `*COPY_CONST*`(remove_reference_t<Self>, variant))` (22.2.4).

10 *Constraints*: The call to `visit` does not use an explicit *template-argument-list* that begins with a type *template-argument*.

11 *Effects*: Equivalent to: `return std::visit(std::forward<Visitor>(vis), (V)self);`

```
template<class R, class Self, class Visitor>
  constexpr R visit(this Self&& self, Visitor&& vis);
```

12 Let `V` be *`OVERRIDE_REF`*`(Self&&, `*`COPY_CONST`*`(remove_reference_t<Self>, variant))` (22.2.4).

13 *Effects*: Equivalent to: `return std::visit<R>(std::forward<Visitor>(vis), (V)self);`

22.6.8 Class `monostate` [variant.monostate]

```
struct monostate{};
```

1 The class `monostate` can serve as a first alternative type for a `variant` to make the `variant` type default constructible.

22.6.9 `monostate` relational operators [variant.monostate.relops]

```
constexpr bool operator==(monostate, monostate) noexcept { return true; }
constexpr strong_ordering operator<=>(monostate, monostate) noexcept
{ return strong_ordering::equal; }
```

1 [*Note 1*: `monostate` objects have only a single state; they thus always compare equal. — *end note*]

22.6.10 Specialized algorithms [variant.specalg]

```
template<class... Types>
  constexpr void swap(variant<Types...>& v, variant<Types...>& w) noexcept(see below);
```

1 *Constraints*: `is_move_constructible_v<`T_i`> && is_swappable_v<`T_i`>` is `true` for all i.

2 *Effects*: Equivalent to `v.swap(w)`.

3 *Remarks*: The exception specification is equivalent to `noexcept(v.swap(w))`.

22.6.11 Class `bad_variant_access` [variant.bad.access]

```
namespace std {
  class bad_variant_access : public exception {
  public:
    // see 17.9.3 for the specification of the special member functions
    constexpr const char* what() const noexcept override;
  };
}
```

1 Objects of type `bad_variant_access` are thrown to report invalid accesses to the value of a `variant` object.

```
constexpr const char* what() const noexcept override;
```

2 *Returns*: An implementation-defined NTBS, which during constant evaluation is encoded with the ordinary literal encoding (5.13.3).

22.6.12 Hash support [variant.hash]

```
template<class... Types> struct hash<variant<Types...>>;
```

1 The specialization `hash<variant<Types...>>` is enabled (22.10.19) if and only if every specialization in `hash<remove_const_t<Types>>...` is enabled. The member functions are not guaranteed to be `noexcept`.

```
template<> struct hash<monostate>;
```

2 The specialization is enabled (22.10.19).

22.7 Storage for any type [any]

22.7.1 General [any.general]

1 Subclause 22.7 describes components that C++ programs may use to perform operations on objects of a discriminated type.

2 [*Note 1*: The discriminated type can contain values of different types but does not attempt conversion between them, i.e., `5` is held strictly as an `int` and is not implicitly convertible either to `"5"` or to `5.0`. This indifference to interpretation but awareness of type effectively allows safe, generic containers of single values, with no scope for surprises from ambiguous conversions. — *end note*]

22.7.2 Header <any> synopsis [any.synop]

```
#include <initializer_list>     // see 17.11.2
#include <typeinfo>             // see 17.7.2

namespace std {
  // 22.7.3, class bad_any_cast
  class bad_any_cast;

  // 22.7.4, class any
  class any;

  // 22.7.5, non-member functions
  void swap(any& x, any& y) noexcept;

  template<class T, class... Args>
    any make_any(Args&&... args);
  template<class T, class U, class... Args>
    any make_any(initializer_list<U> il, Args&&... args);

  template<class T>
    T any_cast(const any& operand);
  template<class T>
    T any_cast(any& operand);
  template<class T>
    T any_cast(any&& operand);

  template<class T>
    const T* any_cast(const any* operand) noexcept;
  template<class T>
    T* any_cast(any* operand) noexcept;
}
```

22.7.3 Class bad_any_cast [any.bad.any.cast]

```
namespace std {
  class bad_any_cast : public bad_cast {
  public:
    // see 17.9.3 for the specification of the special member functions
    const char* what() const noexcept override;
  };
}
```

1 Objects of type `bad_any_cast` are thrown by a failed `any_cast` (22.7.5).

```
const char* what() const noexcept override;
```

2 *Returns*: An implementation-defined NTBS.

22.7.4 Class any [any.class]

22.7.4.1 General [any.class.general]

```
namespace std {
  class any {
  public:
    // 22.7.4.2, construction and destruction
    constexpr any() noexcept;

    any(const any& other);
    any(any&& other) noexcept;
```

```
    template<class T>
      any(T&& value);

    template<class T, class... Args>
      explicit any(in_place_type_t<T>, Args&&...);
    template<class T, class U, class... Args>
      explicit any(in_place_type_t<T>, initializer_list<U>, Args&&...);

    ~any();

    // 22.7.4.3, assignments
    any& operator=(const any& rhs);
    any& operator=(any&& rhs) noexcept;

    template<class T>
      any& operator=(T&& rhs);

    // 22.7.4.4, modifiers
    template<class T, class... Args>
      decay_t<T>& emplace(Args&&...);
    template<class T, class U, class... Args>
      decay_t<T>& emplace(initializer_list<U>, Args&&...);
    void reset() noexcept;
    void swap(any& rhs) noexcept;

    // 22.7.4.5, observers
    bool has_value() const noexcept;
    const type_info& type() const noexcept;
  };
}
```

1 An object of class `any` stores an instance of any type that meets the constructor requirements or it has no value, and this is referred to as the *state* of the class `any` object. The stored instance is called the *contained value*. Two states are equivalent if either they both have no value, or they both have a value and the contained values are equivalent.

2 The non-member `any_cast` functions provide type-safe access to the contained value.

3 Implementations should avoid the use of dynamically allocated memory for a small contained value. However, any such small-object optimization shall only be applied to types `T` for which `is_nothrow_move_constructible_v<T>` is `true`.

[*Example 1*: A contained value of type `int` could be stored in an internal buffer, not in separately-allocated memory. — *end example*]

22.7.4.2 Construction and destruction [any.cons]

```
constexpr any() noexcept;
```

1 *Postconditions*: `has_value()` is `false`.

```
any(const any& other);
```

2 *Effects*: If `other.has_value()` is `false`, constructs an object that has no value. Otherwise, equivalent to `any(in_place_type<T>, any_cast<const T&>(other))` where `T` is the type of the contained value.

3 *Throws*: Any exceptions arising from calling the selected constructor for the contained value.

```
any(any&& other) noexcept;
```

4 *Effects*: If `other.has_value()` is `false`, constructs an object that has no value. Otherwise, constructs an object of type `any` that contains either the contained value of `other`, or contains an object of the same type constructed from the contained value of `other` considering that contained value as an rvalue.

```
template<class T>
  any(T&& value);
```

5 Let `VT` be `decay_t<T>`.

6 *Constraints*: `VT` is not the same type as `any`, `VT` is not a specialization of `in_place_type_t`, and `is_copy_constructible_v<VT>` is `true`.

7 *Preconditions*: `VT` meets the *Cpp17CopyConstructible* requirements.

8 *Effects*: Constructs an object of type `any` that contains an object of type `VT` direct-initialized with `std::forward<T>(value)`.

9 *Throws*: Any exception thrown by the selected constructor of `VT`.

```
template<class T, class... Args>
  explicit any(in_place_type_t<T>, Args&&... args);
```

10 Let `VT` be `decay_t<T>`.

11 *Constraints*: `is_copy_constructible_v<VT>` is `true` and `is_constructible_v<VT, Args...>` is `true`.

12 *Preconditions*: `VT` meets the *Cpp17CopyConstructible* requirements.

13 *Effects*: Direct-non-list-initializes the contained value of type `VT` with `std::forward<Args>(args)...`.

14 *Postconditions*: `*this` contains a value of type `VT`.

15 *Throws*: Any exception thrown by the selected constructor of `VT`.

```
template<class T, class U, class... Args>
  explicit any(in_place_type_t<T>, initializer_list<U> il, Args&&... args);
```

16 Let `VT` be `decay_t<T>`.

17 *Constraints*: `is_copy_constructible_v<VT>` is `true` and `is_constructible_v<VT, initializer_list<U>&, Args...>` is `true`.

18 *Preconditions*: `VT` meets the *Cpp17CopyConstructible* requirements.

19 *Effects*: Direct-non-list-initializes the contained value of type `VT` with `il, std::forward<Args>(args)...`.

20 *Postconditions*: `*this` contains a value.

21 *Throws*: Any exception thrown by the selected constructor of `VT`.

```
~any();
```

22 *Effects*: As if by `reset()`.

22.7.4.3 Assignment [any.assign]

```
any& operator=(const any& rhs);
```

1 *Effects*: As if by `any(rhs).swap(*this)`. No effects if an exception is thrown.

2 *Returns*: `*this`.

3 *Throws*: Any exceptions arising from the copy constructor for the contained value.

```
any& operator=(any&& rhs) noexcept;
```

4 *Effects*: As if by `any(std::move(rhs)).swap(*this)`.

5 *Postconditions*: The state of `*this` is equivalent to the original state of `rhs`.

6 *Returns*: `*this`.

```
template<class T>
  any& operator=(T&& rhs);
```

7 Let `VT` be `decay_t<T>`.

8 *Constraints*: `VT` is not the same type as `any` and `is_copy_constructible_v<VT>` is `true`.

9 *Preconditions*: `VT` meets the *Cpp17CopyConstructible* requirements.

10 *Effects*: Constructs an object `tmp` of type `any` that contains an object of type `VT` direct-initialized with `std::forward<T>(rhs)`, and `tmp.swap(*this)`. No effects if an exception is thrown.

11 *Returns*: `*this`.

12 *Throws*: Any exception thrown by the selected constructor of `VT`.

22.7.4.4 Modifiers [any.modifiers]

```
template<class T, class... Args>
  decay_t<T>& emplace(Args&&... args);
```

1 Let `VT` be `decay_t<T>`.

2 *Constraints*: `is_copy_constructible_v<VT>` is `true` and `is_constructible_v<VT, Args...>` is `true`.

3 *Preconditions*: `VT` meets the *Cpp17CopyConstructible* requirements.

4 *Effects*: Calls `reset()`. Then direct-non-list-initializes the contained value of type `VT` with `std::forward<Args>(args)...`.

5 *Postconditions*: `*this` contains a value.

6 *Returns*: A reference to the new contained value.

7 *Throws*: Any exception thrown by the selected constructor of `VT`.

8 *Remarks*: If an exception is thrown during the call to `VT`'s constructor, `*this` does not contain a value, and any previously contained value has been destroyed.

```
template<class T, class U, class... Args>
  decay_t<T>& emplace(initializer_list<U> il, Args&&... args);
```

9 Let `VT` be `decay_t<T>`.

10 *Constraints*: `is_copy_constructible_v<VT>` is `true` and `is_constructible_v<VT, initializer_list<U>&, Args...>` is `true`.

11 *Preconditions*: `VT` meets the *Cpp17CopyConstructible* requirements.

12 *Effects*: Calls `reset()`. Then direct-non-list-initializes the contained value of type `VT` with `il, std::forward<Args>(args)...`.

13 *Postconditions*: `*this` contains a value.

14 *Returns*: A reference to the new contained value.

15 *Throws*: Any exception thrown by the selected constructor of `VT`.

16 *Remarks*: If an exception is thrown during the call to `VT`'s constructor, `*this` does not contain a value, and any previously contained value has been destroyed.

```
void reset() noexcept;
```

17 *Effects*: If `has_value()` is `true`, destroys the contained value.

18 *Postconditions*: `has_value()` is `false`.

```
void swap(any& rhs) noexcept;
```

19 *Effects*: Exchanges the states of `*this` and `rhs`.

22.7.4.5 Observers [any.observers]

```
bool has_value() const noexcept;
```

1 *Returns*: `true` if `*this` contains an object, otherwise `false`.

```
const type_info& type() const noexcept;
```

2 *Returns*: `typeid(T)` if `*this` has a contained value of type `T`, otherwise `typeid(void)`.

3 [*Note 1*: Useful for querying against types known either at compile time or only at runtime. — *end note*]

22.7.5 Non-member functions [any.nonmembers]

```
void swap(any& x, any& y) noexcept;
```

1 *Effects*: Equivalent to `x.swap(y)`.

```
template<class T, class... Args>
  any make_any(Args&&... args);
```

2 *Effects*: Equivalent to: `return any(in_place_type<T>, std::forward<Args>(args)...);`

```
template<class T, class U, class... Args>
  any make_any(initializer_list<U> il, Args&&... args);
```

3 *Effects*: Equivalent to: `return any(in_place_type<T>, il, std::forward<Args>(args)...);`

```
template<class T>
  T any_cast(const any& operand);
template<class T>
  T any_cast(any& operand);
template<class T>
  T any_cast(any&& operand);
```

4 Let `U` be the type `remove_cvref_t<T>`.

5 *Mandates*: For the first overload, `is_constructible_v<T, const U&>` is `true`. For the second overload, `is_constructible_v<T, U&>` is `true`. For the third overload, `is_constructible_v<T, U>` is `true`.

6 *Returns*: For the first and second overload, `static_cast<T>(*any_cast<U>(&operand))`. For the third overload, `static_cast<T>(std::move(*any_cast<U>(&operand)))`.

7 *Throws*: `bad_any_cast` if `operand.type() != typeid(remove_reference_t<T>)`.

8 [*Example 1*:

```
any x(5);                                  // x holds int
assert(any_cast<int>(x) == 5);             // cast to value
any_cast<int&>(x) = 10;                    // cast to reference
assert(any_cast<int>(x) == 10);

x = "Meow";                                // x holds const char*
assert(strcmp(any_cast<const char*>(x), "Meow") == 0);
any_cast<const char*&>(x) = "Harry";
assert(strcmp(any_cast<const char*>(x), "Harry") == 0);

x = string("Meow");                        // x holds string
string s, s2("Jane");
s = move(any_cast<string&>(x));            // move from any
assert(s == "Meow");
any_cast<string&>(x) = move(s2);           // move to any
assert(any_cast<const string&>(x) == "Jane");

string cat("Meow");
const any y(cat);                          // const y holds string
assert(any_cast<const string&>(y) == cat);

any_cast<string&>(y);                      // error: cannot any_cast away const
```

— *end example*]

```
template<class T>
  const T* any_cast(const any* operand) noexcept;
template<class T>
  T* any_cast(any* operand) noexcept;
```

9 *Mandates*: `is_void_v<T>` is `false`.

10 *Returns*: If `operand != nullptr && operand->type() == typeid(T)` is `true`, a pointer to the object contained by `operand`; otherwise, `nullptr`.

11 [*Example 2*:

```
bool is_string(const any& operand) {
  return any_cast<string>(&operand) != nullptr;
}
```

— *end example*]

22.8 Expected objects [expected]

22.8.1 General [expected.general]

[1] Subclause 22.8 describes the class template `expected` that represents expected objects. An `expected<T, E>` object holds an object of type `T` or an object of type `E` and manages the lifetime of the contained objects.

22.8.2 Header <expected> synopsis [expected.syn]

```
// mostly freestanding
namespace std {
  // 22.8.3, class template unexpected
  template<class E> class unexpected;

  // 22.8.4, class template bad_expected_access
  template<class E> class bad_expected_access;

  // 22.8.5, specialization for void
  template<> class bad_expected_access<void>;

  // in-place construction of unexpected values
  struct unexpect_t {
    explicit unexpect_t() = default;
  };
  inline constexpr unexpect_t unexpect{};

  // 22.8.6, class template expected
  template<class T, class E> class expected;                                  // partially freestanding

  // 22.8.7, partial specialization of expected for void types
  template<class T, class E> requires is_void_v<T> class expected<T, E>;      // partially freestanding
}
```

22.8.3 Class template unexpected [expected.unexpected]

22.8.3.1 General [expected.un.general]

[1] Subclause 22.8.3 describes the class template `unexpected` that represents unexpected objects stored in `expected` objects.

```
namespace std {
  template<class E>
  class unexpected {
  public:
    // 22.8.3.2, constructors
    constexpr unexpected(const unexpected&) = default;
    constexpr unexpected(unexpected&&) = default;
    template<class Err = E>
      constexpr explicit unexpected(Err&&);
    template<class... Args>
      constexpr explicit unexpected(in_place_t, Args&&...);
    template<class U, class... Args>
      constexpr explicit unexpected(in_place_t, initializer_list<U>, Args&&...);

    constexpr unexpected& operator=(const unexpected&) = default;
    constexpr unexpected& operator=(unexpected&&) = default;

    constexpr const E& error() const & noexcept;
    constexpr E& error() & noexcept;
    constexpr const E&& error() const && noexcept;
    constexpr E&& error() && noexcept;

    constexpr void swap(unexpected& other) noexcept(see below);

    template<class E2>
      friend constexpr bool operator==(const unexpected&, const unexpected<E2>&);
```

```
    friend constexpr void swap(unexpected& x, unexpected& y) noexcept(noexcept(x.swap(y)));

  private:
    E unex;              // exposition only
  };

  template<class E> unexpected(E) -> unexpected<E>;
}
```

2 A program that instantiates the definition of `unexpected` for a non-object type, an array type, a specialization of `unexpected`, or a cv-qualified type is ill-formed.

22.8.3.2 Constructors [expected.un.cons]

```
template<class Err = E>
  constexpr explicit unexpected(Err&& e);
```

1 *Constraints*:

(1.1) — `is_same_v<remove_cvref_t<Err>, unexpected>` is `false`; and

(1.2) — `is_same_v<remove_cvref_t<Err>, in_place_t>` is `false`; and

(1.3) — `is_constructible_v<E, Err>` is `true`.

2 *Effects*: Direct-non-list-initializes *unex* with `std::forward<Err>(e)`.

3 *Throws*: Any exception thrown by the initialization of *unex*.

```
template<class... Args>
  constexpr explicit unexpected(in_place_t, Args&&... args);
```

4 *Constraints*: `is_constructible_v<E, Args...>` is `true`.

5 *Effects*: Direct-non-list-initializes *unex* with `std::forward<Args>(args)...`.

6 *Throws*: Any exception thrown by the initialization of *unex*.

```
template<class U, class... Args>
  constexpr explicit unexpected(in_place_t, initializer_list<U> il, Args&&... args);
```

7 *Constraints*: `is_constructible_v<E, initializer_list<U>&, Args...>` is `true`.

8 *Effects*: Direct-non-list-initializes *unex* with `il, std::forward<Args>(args)...`.

9 *Throws*: Any exception thrown by the initialization of *unex*.

22.8.3.3 Observers [expected.un.obs]

```
constexpr const E& error() const & noexcept;
constexpr E& error() & noexcept;
```

1 *Returns*: *unex*.

```
constexpr E&& error() && noexcept;
constexpr const E&& error() const && noexcept;
```

2 *Returns*: `std::move(`*unex*`)`.

22.8.3.4 Swap [expected.un.swap]

```
constexpr void swap(unexpected& other) noexcept(is_nothrow_swappable_v<E>);
```

1 *Mandates*: `is_swappable_v<E>` is `true`.

2 *Effects*: Equivalent to: `using std::swap; swap(`*unex*`, other.`*unex*`);`

```
friend constexpr void swap(unexpected& x, unexpected& y) noexcept(noexcept(x.swap(y)));
```

3 *Constraints*: `is_swappable_v<E>` is `true`.

4 *Effects*: Equivalent to `x.swap(y)`.

22.8.3.5 Equality operator [expected.un.eq]

```
template<class E2>
  friend constexpr bool operator==(const unexpected& x, const unexpected<E2>& y);
```

1 *Mandates*: The expression `x.error() == y.error()` is well-formed and its result is convertible to `bool`.

2 *Returns*: `x.error() == y.error()`.

22.8.4 Class template `bad_expected_access` [expected.bad]

```
namespace std {
  template<class E>
  class bad_expected_access : public bad_expected_access<void> {
  public:
    constexpr explicit bad_expected_access(E);
    constexpr const char* what() const noexcept override;
    constexpr E& error() & noexcept;
    constexpr const E& error() const & noexcept;
    constexpr E&& error() && noexcept;
    constexpr const E&& error() const && noexcept;

  private:
    E unex;              // exposition only
  };
}
```

1 The class template `bad_expected_access` defines the type of objects thrown as exceptions to report the situation where an attempt is made to access the value of an `expected<T, E>` object for which `has_value()` is `false`.

```
constexpr explicit bad_expected_access(E e);
```

2 *Effects*: Initializes *unex* with `std::move(e)`.

```
constexpr const E& error() const & noexcept;
constexpr E& error() & noexcept;
```

3 *Returns*: *unex*.

```
constexpr E&& error() && noexcept;
constexpr const E&& error() const && noexcept;
```

4 *Returns*: `std::move(`*unex*`)`.

```
constexpr const char* what() const noexcept override;
```

5 *Returns*: An implementation-defined NTBS, which during constant evaluation is encoded with the ordinary literal encoding (5.13.3).

22.8.5 Class template specialization `bad_expected_access<void>` [expected.bad.void]

```
namespace std {
  template<>
  class bad_expected_access<void> : public exception {
  protected:
    constexpr bad_expected_access() noexcept;
    constexpr bad_expected_access(const bad_expected_access&) noexcept;
    constexpr bad_expected_access(bad_expected_access&&) noexcept;
    constexpr bad_expected_access& operator=(const bad_expected_access&) noexcept;
    constexpr bad_expected_access& operator=(bad_expected_access&&) noexcept;
    constexpr ~bad_expected_access();

  public:
    constexpr const char* what() const noexcept override;
  };
}
```

```
constexpr const char* what() const noexcept override;
```

1 *Returns*: An implementation-defined NTBS, which during constant evaluation is encoded with the ordinary literal encoding (5.13.3).

22.8.6 Class template expected [expected.expected]

22.8.6.1 General [expected.object.general]

```
namespace std {
  template<class T, class E>
  class expected {
  public:
    using value_type = T;
    using error_type = E;
    using unexpected_type = unexpected<E>;

    template<class U>
    using rebind = expected<U, error_type>;

    // 22.8.6.2, constructors
    constexpr expected();
    constexpr expected(const expected&);
    constexpr expected(expected&&) noexcept(see below);
    template<class U, class G>
      constexpr explicit(see below) expected(const expected<U, G>&);
    template<class U, class G>
      constexpr explicit(see below) expected(expected<U, G>&&);

    template<class U = remove_cv_t<T>>
      constexpr explicit(see below) expected(U&& v);

    template<class G>
      constexpr explicit(see below) expected(const unexpected<G>&);
    template<class G>
      constexpr explicit(see below) expected(unexpected<G>&&);

    template<class... Args>
      constexpr explicit expected(in_place_t, Args&&...);
    template<class U, class... Args>
      constexpr explicit expected(in_place_t, initializer_list<U>, Args&&...);
    template<class... Args>
      constexpr explicit expected(unexpect_t, Args&&...);
    template<class U, class... Args>
      constexpr explicit expected(unexpect_t, initializer_list<U>, Args&&...);

    // 22.8.6.3, destructor
    constexpr ~expected();

    // 22.8.6.4, assignment
    constexpr expected& operator=(const expected&);
    constexpr expected& operator=(expected&&) noexcept(see below);
    template<class U = remove_cv_t<T>> constexpr expected& operator=(U&&);
    template<class G>
      constexpr expected& operator=(const unexpected<G>&);
    template<class G>
      constexpr expected& operator=(unexpected<G>&&);

    template<class... Args>
      constexpr T& emplace(Args&&...) noexcept;
    template<class U, class... Args>
      constexpr T& emplace(initializer_list<U>, Args&&...) noexcept;

    // 22.8.6.5, swap
    constexpr void swap(expected&) noexcept(see below);
    friend constexpr void swap(expected& x, expected& y) noexcept(noexcept(x.swap(y)));
```

```
    // 22.8.6.6, observers
    constexpr const T* operator->() const noexcept;
    constexpr T* operator->() noexcept;
    constexpr const T& operator*() const & noexcept;
    constexpr T& operator*() & noexcept;
    constexpr const T&& operator*() const && noexcept;
    constexpr T&& operator*() && noexcept;
    constexpr explicit operator bool() const noexcept;
    constexpr bool has_value() const noexcept;
    constexpr const T& value() const &;                          // freestanding-deleted
    constexpr T& value() &;                                      // freestanding-deleted
    constexpr const T&& value() const &&;                        // freestanding-deleted
    constexpr T&& value() &&;                                    // freestanding-deleted
    constexpr const E& error() const & noexcept;
    constexpr E& error() & noexcept;
    constexpr const E&& error() const && noexcept;
    constexpr E&& error() && noexcept;
    template<class U = remove_cv_t<T>> constexpr T value_or(U&&) const &;
    template<class U = remove_cv_t<T>> constexpr T value_or(U&&) &&;
    template<class G = E> constexpr E error_or(G&&) const &;
    template<class G = E> constexpr E error_or(G&&) &&;

    // 22.8.6.7, monadic operations
    template<class F> constexpr auto and_then(F&& f) &;
    template<class F> constexpr auto and_then(F&& f) &&;
    template<class F> constexpr auto and_then(F&& f) const &;
    template<class F> constexpr auto and_then(F&& f) const &&;
    template<class F> constexpr auto or_else(F&& f) &;
    template<class F> constexpr auto or_else(F&& f) &&;
    template<class F> constexpr auto or_else(F&& f) const &;
    template<class F> constexpr auto or_else(F&& f) const &&;
    template<class F> constexpr auto transform(F&& f) &;
    template<class F> constexpr auto transform(F&& f) &&;
    template<class F> constexpr auto transform(F&& f) const &;
    template<class F> constexpr auto transform(F&& f) const &&;
    template<class F> constexpr auto transform_error(F&& f) &;
    template<class F> constexpr auto transform_error(F&& f) &&;
    template<class F> constexpr auto transform_error(F&& f) const &;
    template<class F> constexpr auto transform_error(F&& f) const &&;

    // 22.8.6.8, equality operators
    template<class T2, class E2> requires (!is_void_v<T2>)
      friend constexpr bool operator==(const expected& x, const expected<T2, E2>& y);
    template<class T2>
      friend constexpr bool operator==(const expected&, const T2&);
    template<class E2>
      friend constexpr bool operator==(const expected&, const unexpected<E2>&);

  private:
    bool has_val;            // exposition only
    union {
      remove_cv_t<T> val;    // exposition only
      E unex;                // exposition only
    };
  };
}
```

1 Any object of type `expected<T, E>` either contains a value of type `T` or a value of type `E` nested within (6.8.2) it. Member *`has_val`* indicates whether the `expected<T, E>` object contains an object of type `T`.

2 A type `T` is a *valid value type for* ***`expected`***, if `remove_cv_t<T>` is `void` or a complete non-array object type that is not `in_place_t`, `unexpect_t`, or a specialization of `unexpected`. A program which instantiates class template `expected<T, E>` with an argument `T` that is not a valid value type for `expected` is ill-formed. A

program that instantiates the definition of the template `expected<T, E>` with a type for the `E` parameter that is not a valid template argument for `unexpected` is ill-formed.

3 When `T` is not *cv* `void`, it shall meet the *Cpp17Destructible* requirements (Table 35). `E` shall meet the *Cpp17Destructible* requirements.

22.8.6.2 Constructors [expected.object.cons]

1 The exposition-only variable template *converts-from-any-cvref* defined in 22.5.3.2 is used by some constructors for `expected`.

```
constexpr expected();
```

2 *Constraints*: `is_default_constructible_v<T>` is `true`.

3 *Effects*: Value-initializes *val*.

4 *Postconditions*: `has_value()` is `true`.

5 *Throws*: Any exception thrown by the initialization of *val*.

```
constexpr expected(const expected& rhs);
```

6 *Effects*: If `rhs.has_value()` is `true`, direct-non-list-initializes *val* with `*rhs`. Otherwise, direct-non-list-initializes *unex* with `rhs.error()`.

7 *Postconditions*: `rhs.has_value() == this->has_value()`.

8 *Throws*: Any exception thrown by the initialization of *val* or *unex*.

9 *Remarks*: This constructor is defined as deleted unless

(9.1) — `is_copy_constructible_v<T>` is `true` and

(9.2) — `is_copy_constructible_v<E>` is `true`.

10 This constructor is trivial if

(10.1) — `is_trivially_copy_constructible_v<T>` is `true` and

(10.2) — `is_trivially_copy_constructible_v<E>` is `true`.

```
constexpr expected(expected&& rhs) noexcept(see below);
```

11 *Constraints*:

(11.1) — `is_move_constructible_v<T>` is `true` and

(11.2) — `is_move_constructible_v<E>` is `true`.

12 *Effects*: If `rhs.has_value()` is `true`, direct-non-list-initializes *val* with `std::move(*rhs)`. Otherwise, direct-non-list-initializes *unex* with `std::move(rhs.error())`.

13 *Postconditions*: `rhs.has_value()` is unchanged; `rhs.has_value() == this->has_value()` is `true`.

14 *Throws*: Any exception thrown by the initialization of *val* or *unex*.

15 *Remarks*: The exception specification is equivalent to `is_nothrow_move_constructible_v<T> && is_nothrow_move_constructible_v<E>`.

16 This constructor is trivial if

(16.1) — `is_trivially_move_constructible_v<T>` is `true` and

(16.2) — `is_trivially_move_constructible_v<E>` is `true`.

```
template<class U, class G>
  constexpr explicit(see below) expected(const expected<U, G>& rhs);
template<class U, class G>
  constexpr explicit(see below) expected(expected<U, G>&& rhs);
```

17 Let:

(17.1) — `UF` be `const U&` for the first overload and `U` for the second overload.

(17.2) — `GF` be `const G&` for the first overload and `G` for the second overload.

18 *Constraints*:

(18.1) — `is_constructible_v<T, UF>` is `true`; and

(18.2) — `is_constructible_v<E, GF>` is `true`; and

(18.3) — if `T` is not *cv* `bool`, *`converts-from-any-cvref`*`<T, expected<U, G>>` is `false`; and

(18.4) — `is_constructible_v<unexpected<E>, expected<U, G>&>` is `false`; and

(18.5) — `is_constructible_v<unexpected<E>, expected<U, G>>` is `false`; and

(18.6) — `is_constructible_v<unexpected<E>, const expected<U, G>&>` is `false`; and

(18.7) — `is_constructible_v<unexpected<E>, const expected<U, G>>` is `false`.

19 *Effects*: If `rhs.has_value()`, direct-non-list-initializes *`val`* with `std::forward<UF>(*rhs)`. Otherwise, direct-non-list-initializes *`unex`* with `std::forward<GF>(rhs.error())`.

20 *Postconditions*: `rhs.has_value()` is unchanged; `rhs.has_value() == this->has_value()` is `true`.

21 *Throws*: Any exception thrown by the initialization of *`val`* or *`unex`*.

22 *Remarks*: The expression inside `explicit` is equivalent to `!is_convertible_v<UF, T> || !is_convertible_v<GF, E>`.

```
template<class U = remove_cv_t<T>>
  constexpr explicit(!is_convertible_v<U, T>) expected(U&& v);
```

23 *Constraints*:

(23.1) — `is_same_v<remove_cvref_t<U>, in_place_t>` is `false`; and

(23.2) — `is_same_v<remove_cvref_t<U>, expected>` is `false`; and

(23.3) — `is_same_v<remove_cvref_t<U>, unexpect_t>` is `false`; and

(23.4) — `remove_cvref_t<U>` is not a specialization of `unexpected`; and

(23.5) — `is_constructible_v<T, U>` is `true`; and

(23.6) — if `T` is *cv* `bool`, `remove_cvref_t<U>` is not a specialization of `expected`.

24 *Effects*: Direct-non-list-initializes *`val`* with `std::forward<U>(v)`.

25 *Postconditions*: `has_value()` is `true`.

26 *Throws*: Any exception thrown by the initialization of *`val`*.

```
template<class G>
  constexpr explicit(!is_convertible_v<const G&, E>) expected(const unexpected<G>& e);
template<class G>
  constexpr explicit(!is_convertible_v<G, E>) expected(unexpected<G>&& e);
```

27 Let `GF` be `const G&` for the first overload and `G` for the second overload.

28 *Constraints*: `is_constructible_v<E, GF>` is `true`.

29 *Effects*: Direct-non-list-initializes *`unex`* with `std::forward<GF>(e.error())`.

30 *Postconditions*: `has_value()` is `false`.

31 *Throws*: Any exception thrown by the initialization of *`unex`*.

```
template<class... Args>
  constexpr explicit expected(in_place_t, Args&&... args);
```

32 *Constraints*: `is_constructible_v<T, Args...>` is `true`.

33 *Effects*: Direct-non-list-initializes *`val`* with `std::forward<Args>(args)...`.

34 *Postconditions*: `has_value()` is `true`.

35 *Throws*: Any exception thrown by the initialization of *`val`*.

```
template<class U, class... Args>
  constexpr explicit expected(in_place_t, initializer_list<U> il, Args&&... args);
```

36 *Constraints*: `is_constructible_v<T, initializer_list<U>&, Args...>` is `true`.

37 *Effects*: Direct-non-list-initializes *`val`* with `il, std::forward<Args>(args)...`.

38 *Postconditions*: `has_value()` is `true`.

39 *Throws*: Any exception thrown by the initialization of *`val`*.

```
template<class... Args>
  constexpr explicit expected(unexpect_t, Args&&... args);
```

40 *Constraints*: `is_constructible_v<E, Args...>` is `true`.

41 *Effects*: Direct-non-list-initializes *unex* with `std::forward<Args>(args)...`.

42 *Postconditions*: `has_value()` is `false`.

43 *Throws*: Any exception thrown by the initialization of *unex*.

```
template<class U, class... Args>
  constexpr explicit expected(unexpect_t, initializer_list<U> il, Args&&... args);
```

44 *Constraints*: `is_constructible_v<E, initializer_list<U>&, Args...>` is `true`.

45 *Effects*: Direct-non-list-initializes *unex* with `il, std::forward<Args>(args)...`.

46 *Postconditions*: `has_value()` is `false`.

47 *Throws*: Any exception thrown by the initialization of *unex*.

22.8.6.3 Destructor [expected.object.dtor]

```
constexpr ~expected();
```

1 *Effects*: If `has_value()` is `true`, destroys *val*, otherwise destroys *unex*.

2 *Remarks*: If `is_trivially_destructible_v<T>` is `true`, and `is_trivially_destructible_v<E>` is `true`, then this destructor is a trivial destructor.

22.8.6.4 Assignment [expected.object.assign]

1 This subclause makes use of the following exposition-only function template:

```
template<class T, class U, class... Args>
constexpr void reinit-expected(T& newval, U& oldval, Args&&... args) {  // exposition only
  if constexpr (is_nothrow_constructible_v<T, Args...>) {
    destroy_at(addressof(oldval));
    construct_at(addressof(newval), std::forward<Args>(args)...);
  } else if constexpr (is_nothrow_move_constructible_v<T>) {
    T tmp(std::forward<Args>(args)...);
    destroy_at(addressof(oldval));
    construct_at(addressof(newval), std::move(tmp));
  } else {
    U tmp(std::move(oldval));
    destroy_at(addressof(oldval));
    try {
      construct_at(addressof(newval), std::forward<Args>(args)...);
    } catch (...) {
      construct_at(addressof(oldval), std::move(tmp));
      throw;
    }
  }
}
```

```
constexpr expected& operator=(const expected& rhs);
```

2 *Effects*:

(2.1) — If `this->has_value() && rhs.has_value()` is `true`, equivalent to *val* `= *rhs`.

(2.2) — Otherwise, if `this->has_value()` is `true`, equivalent to:

reinit-expected(*unex*, *val*, `rhs.error()`)

(2.3) — Otherwise, if `rhs.has_value()` is `true`, equivalent to:

reinit-expected(*val*, *unex*, `*rhs`)

(2.4) — Otherwise, equivalent to *unex* `= rhs.error()`.

Then, if no exception was thrown, equivalent to: *has_val* `= rhs.has_value(); return *this;`

3 *Returns*: `*this`.

4 *Remarks*: This operator is defined as deleted unless:

(4.1) — `is_copy_assignable_v<T>` is `true` and

(4.2) — `is_copy_constructible_v<T>` is `true` and

(4.3) — `is_copy_assignable_v<E>` is `true` and

(4.4) — `is_copy_constructible_v<E>` is `true` and

(4.5) — `is_nothrow_move_constructible_v<T> || is_nothrow_move_constructible_v<E>` is `true`.

5 This operator is trivial if:

(5.1) — `is_trivially_copy_constructible_v<T>` is `true`, and

(5.2) — `is_trivially_copy_assignable_v<T>` is `true`, and

(5.3) — `is_trivially_destructible_v<T>` is `true`, and

(5.4) — `is_trivially_copy_constructible_v<E>` is `true`, and

(5.5) — `is_trivially_copy_assignable_v<E>` is `true`, and

(5.6) — `is_trivially_destructible_v<E>` is `true`.

```
constexpr expected& operator=(expected&& rhs) noexcept(see below);
```

6 *Constraints*:

(6.1) — `is_move_constructible_v<T>` is `true` and

(6.2) — `is_move_assignable_v<T>` is `true` and

(6.3) — `is_move_constructible_v<E>` is `true` and

(6.4) — `is_move_assignable_v<E>` is `true` and

(6.5) — `is_nothrow_move_constructible_v<T> || is_nothrow_move_constructible_v<E>` is `true`.

7 *Effects*:

(7.1) — If `this->has_value() && rhs.has_value()` is `true`, equivalent to *`val`* `= std::move(*rhs)`.

(7.2) — Otherwise, if `this->has_value()` is `true`, equivalent to:

`reinit-expected``(`*`unex`*`, `*`val`*`, std::move(rhs.error()))`

(7.3) — Otherwise, if `rhs.has_value()` is `true`, equivalent to:

`reinit-expected``(`*`val`*`, `*`unex`*`, std::move(*rhs))`

(7.4) — Otherwise, equivalent to *`unex`* `= std::move(rhs.error())`.

Then, if no exception was thrown, equivalent to: `has_val = rhs.has_value(); return *this;`

8 *Returns*: `*this`.

9 *Remarks*: The exception specification is equivalent to:

```
is_nothrow_move_assignable_v<T> && is_nothrow_move_constructible_v<T> &&
is_nothrow_move_assignable_v<E> && is_nothrow_move_constructible_v<E>
```

10 This operator is trivial if:

(10.1) — `is_trivially_move_constructible_v<T>` is `true`, and

(10.2) — `is_trivially_move_assignable_v<T>` is `true`, and

(10.3) — `is_trivially_destructible_v<T>` is `true`, and

(10.4) — `is_trivially_move_constructible_v<E>` is `true`, and

(10.5) — `is_trivially_move_assignable_v<E>` is `true`, and

(10.6) — `is_trivially_destructible_v<E>` is `true`.

```
template<class U = remove_cv_t<T>>
  constexpr expected& operator=(U&& v);
```

11 *Constraints*:

(11.1) — `is_same_v<expected, remove_cvref_t<U>>` is `false`; and

(11.2) — `remove_cvref_t<U>` is not a specialization of `unexpected`; and

(11.3) — `is_constructible_v<T, U>` is `true`; and

(11.4) — `is_assignable_v<T&, U>` is `true`; and

(11.5) — `is_nothrow_constructible_v<T, U> || is_nothrow_move_constructible_v<T> || is_nothrow_move_constructible_v<E>` is `true`.

12 *Effects*:

(12.1) — If `has_value()` is `true`, equivalent to: *val* `= std::forward<U>(v);`

(12.2) — Otherwise, equivalent to:

```
reinit-expected(val, unex, std::forward<U>(v));
has_val = true;
```

13 *Returns*: `*this`.

```
template<class G>
  constexpr expected& operator=(const unexpected<G>& e);
template<class G>
  constexpr expected& operator=(unexpected<G>&& e);
```

14 Let `GF` be `const G&` for the first overload and `G` for the second overload.

15 *Constraints*:

(15.1) — `is_constructible_v<E, GF>` is `true`; and

(15.2) — `is_assignable_v<E&, GF>` is `true`; and

(15.3) — `is_nothrow_constructible_v<E, GF> || is_nothrow_move_constructible_v<T> || is_nothrow_move_constructible_v<E>` is `true`.

16 *Effects*:

(16.1) — If `has_value()` is `true`, equivalent to:

```
reinit-expected(unex, val, std::forward<GF>(e.error()));
has_val = false;
```

(16.2) — Otherwise, equivalent to: *unex* `= std::forward<GF>(e.error());`

17 *Returns*: `*this`.

```
template<class... Args>
  constexpr T& emplace(Args&&... args) noexcept;
```

18 *Constraints*: `is_nothrow_constructible_v<T, Args...>` is `true`.

19 *Effects*: Equivalent to:

```
if (has_value()) {
  destroy_at(addressof(val));
} else {
  destroy_at(addressof(unex));
  has_val = true;
}
return *construct_at(addressof(val), std::forward<Args>(args)...);
```

```
template<class U, class... Args>
  constexpr T& emplace(initializer_list<U> il, Args&&... args) noexcept;
```

20 *Constraints*: `is_nothrow_constructible_v<T, initializer_list<U>&, Args...>` is `true`.

21 *Effects*: Equivalent to:

```
if (has_value()) {
  destroy_at(addressof(val));
} else {
  destroy_at(addressof(unex));
  has_val = true;
}
return *construct_at(addressof(val), il, std::forward<Args>(args)...);
```

22.8.6.5 Swap [expected.object.swap]

```
constexpr void swap(expected& rhs) noexcept(see below);
```

1 *Constraints*:

(1.1) — `is_swappable_v<T>` is `true` and

(1.2) — `is_swappable_v<E>` is `true` and

(1.3) — `is_move_constructible_v<T> && is_move_constructible_v<E>` is `true`, and

(1.4) — `is_nothrow_move_constructible_v<T> || is_nothrow_move_constructible_v<E>` is `true`.

2 *Effects*: See Table 72.

Table 72 — `swap(expected&)` effects [tab:expected.object.swap]

	`this->has_value()`	`!this->has_value()`
`rhs.has_value()`	equivalent to: `using std::swap; swap(val, rhs.val);`	calls `rhs.swap(*this)`
`!rhs.has_value()`	*see below*	equivalent to: `using std::swap; swap(unex, rhs.unex);`

For the case where `rhs.has_value()` is `false` and `this->has_value()` is `true`, equivalent to:

```
if constexpr (is_nothrow_move_constructible_v<E>) {
  E tmp(std::move(rhs.unex));
  destroy_at(addressof(rhs.unex));
  try {
    construct_at(addressof(rhs.val), std::move(val));
    destroy_at(addressof(val));
    construct_at(addressof(unex), std::move(tmp));
  } catch(...) {
    construct_at(addressof(rhs.unex), std::move(tmp));
    throw;
  }
} else {
  remove_cv_t<T> tmp(std::move(val));
  destroy_at(addressof(val));
  try {
    construct_at(addressof(unex), std::move(rhs.unex));
    destroy_at(addressof(rhs.unex));
    construct_at(addressof(rhs.val), std::move(tmp));
  } catch (...) {
    construct_at(addressof(val), std::move(tmp));
    throw;
  }
}
has_val = false;
rhs.has_val = true;
```

3 *Throws*: Any exception thrown by the expressions in the *Effects*.

4 *Remarks*: The exception specification is equivalent to:

```
is_nothrow_move_constructible_v<T> && is_nothrow_swappable_v<T> &&
is_nothrow_move_constructible_v<E> && is_nothrow_swappable_v<E>
```

```
friend constexpr void swap(expected& x, expected& y) noexcept(noexcept(x.swap(y)));
```

5 *Effects*: Equivalent to `x.swap(y)`.

22.8.6.6 Observers [expected.object.obs]

```
constexpr const T* operator->() const noexcept;
constexpr T* operator->() noexcept;
```

1 *Hardened preconditions*: `has_value()` is `true`.

2 *Returns*: `addressof(`*`val`*`)`.

```
constexpr const T& operator*() const & noexcept;
constexpr T& operator*() & noexcept;
```

3 *Hardened preconditions*: `has_value()` is `true`.

4 *Returns*: *`val`*.

```
constexpr T&& operator*() && noexcept;
constexpr const T&& operator*() const && noexcept;
```

5 *Hardened preconditions*: `has_value()` is `true`.

6 *Returns*: `std::move(`*`val`*`)`.

```
constexpr explicit operator bool() const noexcept;
constexpr bool has_value() const noexcept;
```

7 *Returns*: *`has_val`*.

```
constexpr const T& value() const &;
constexpr T& value() &;
```

8 *Mandates*: `is_copy_constructible_v<E>` is `true`.

9 *Returns*: *`val`*, if `has_value()` is `true`.

10 *Throws*: `bad_expected_access(as_const(error()))` if `has_value()` is `false`.

```
constexpr T&& value() &&;
constexpr const T&& value() const &&;
```

11 *Mandates*: `is_copy_constructible_v<E>` is `true` and `is_constructible_v<E, decltype(std::move(error()))>` is `true`.

12 *Returns*: `std::move(`*`val`*`)`, if `has_value()` is `true`.

13 *Throws*: `bad_expected_access(std::move(error()))` if `has_value()` is `false`.

```
constexpr const E& error() const & noexcept;
constexpr E& error() & noexcept;
```

14 *Hardened preconditions*: `has_value()` is `false`.

15 *Returns*: *`unex`*.

```
constexpr E&& error() && noexcept;
constexpr const E&& error() const && noexcept;
```

16 *Hardened preconditions*: `has_value()` is `false`.

17 *Returns*: `std::move(`*`unex`*`)`.

```
template<class U = remove_cv_t<T>> constexpr T value_or(U&& v) const &;
```

18 *Mandates*: `is_copy_constructible_v<T>` is `true` and `is_convertible_v<U, T>` is `true`.

19 *Returns*: `has_value() ? **this : static_cast<T>(std::forward<U>(v))`.

```
template<class U = remove_cv_t<T>> constexpr T value_or(U&& v) &&;
```

20 *Mandates*: `is_move_constructible_v<T>` is `true` and `is_convertible_v<U, T>` is `true`.

21 *Returns*: `has_value() ? std::move(**this) : static_cast<T>(std::forward<U>(v))`.

```
template<class G = E> constexpr E error_or(G&& e) const &;
```

22 *Mandates*: `is_copy_constructible_v<E>` is `true` and `is_convertible_v<G, E>` is `true`.

23 *Returns*: `std::forward<G>(e)` if `has_value()` is `true`, `error()` otherwise.

```
template<class G = E> constexpr E error_or(G&& e) &&;
```

24 *Mandates*: `is_move_constructible_v<E>` is `true` and `is_convertible_v<G, E>` is `true`.

25 *Returns*: `std::forward<G>(e)` if `has_value()` is `true`, `std::move(error())` otherwise.

22.8.6.7 Monadic operations [expected.object.monadic]

```
template<class F> constexpr auto and_then(F&& f) &;
template<class F> constexpr auto and_then(F&& f) const &;
```

1 Let `U` be `remove_cvref_t<invoke_result_t<F, decltype((val))>>`.

2 *Constraints*: `is_constructible_v<E, decltype(error())>` is `true`.

3 *Mandates*: `U` is a specialization of `expected` and `is_same_v<typename U::error_type, E>` is `true`.

4 *Effects*: Equivalent to:

```
if (has_value())
  return invoke(std::forward<F>(f), val);
else
  return U(unexpect, error());
```

```
template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &&;
```

5 Let `U` be `remove_cvref_t<invoke_result_t<F, decltype(std::move(val))>>`.

6 *Constraints*: `is_constructible_v<E, decltype(std::move(error()))>` is `true`.

7 *Mandates*: `U` is a specialization of `expected` and `is_same_v<typename U::error_type, E>` is `true`.

8 *Effects*: Equivalent to:

```
if (has_value())
  return invoke(std::forward<F>(f), std::move(val));
else
  return U(unexpect, std::move(error()));
```

```
template<class F> constexpr auto or_else(F&& f) &;
template<class F> constexpr auto or_else(F&& f) const &;
```

9 Let `G` be `remove_cvref_t<invoke_result_t<F, decltype(error())>>`.

10 *Constraints*: `is_constructible_v<T, decltype((val))>` is `true`.

11 *Mandates*: `G` is a specialization of `expected` and `is_same_v<typename G::value_type, T>` is `true`.

12 *Effects*: Equivalent to:

```
if (has_value())
  return G(in_place, val);
else
  return invoke(std::forward<F>(f), error());
```

```
template<class F> constexpr auto or_else(F&& f) &&;
template<class F> constexpr auto or_else(F&& f) const &&;
```

13 Let `G` be `remove_cvref_t<invoke_result_t<F, decltype(std::move(error()))>>`.

14 *Constraints*: `is_constructible_v<T, decltype(std::move(val))>` is `true`.

15 *Mandates*: `G` is a specialization of `expected` and `is_same_v<typename G::value_type, T>` is `true`.

16 *Effects*: Equivalent to:

```
if (has_value())
  return G(in_place, std::move(val));
else
  return invoke(std::forward<F>(f), std::move(error()));
```

```
template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) const &;
```

17 Let `U` be `remove_cv_t<invoke_result_t<F, decltype((val))>>`.

18 *Constraints*: `is_constructible_v<E, decltype(error())>` is `true`.

19 *Mandates*: `U` is a valid value type for `expected`. If `is_void_v<U>` is `false`, the declaration

```
U u(invoke(std::forward<F>(f), val));
```

is well-formed.

20 *Effects*:

(20.1) — If `has_value()` is `false`, returns `expected<U, E>(unexpect, error())`.

(20.2) — Otherwise, if `is_void_v<U>` is `false`, returns an `expected<U, E>` object whose *`has_val`* member is `true` and *`val`* member is direct-non-list-initialized with `invoke(std::forward<F>(f), val)`.

(20.3) — Otherwise, evaluates `invoke(std::forward<F>(f), val)` and then returns `expected<U, E>()`.

```
template<class F> constexpr auto transform(F&& f) &&;
template<class F> constexpr auto transform(F&& f) const &&;
```

21 Let `U` be `remove_cv_t<invoke_result_t<F, decltype(std::move(val))>>`.

22 *Constraints*: `is_constructible_v<E, decltype(std::move(error()))>` is `true`.

23 *Mandates*: `U` is a valid value type for `expected`. If `is_void_v<U>` is `false`, the declaration

```
U u(invoke(std::forward<F>(f), std::move(val)));
```

is well-formed.

24 *Effects*:

(24.1) — If `has_value()` is `false`, returns `expected<U, E>(unexpect, std::move(error()))`.

(24.2) — Otherwise, if `is_void_v<U>` is `false`, returns an `expected<U, E>` object whose *`has_val`* member is `true` and *`val`* member is direct-non-list-initialized with `invoke(std::forward<F>(f), std::move(val))`.

(24.3) — Otherwise, evaluates `invoke(std::forward<F>(f), std::move(val))` and then returns `expected<U, E>()`.

```
template<class F> constexpr auto transform_error(F&& f) &;
template<class F> constexpr auto transform_error(F&& f) const &;
```

25 Let `G` be `remove_cv_t<invoke_result_t<F, decltype(error())>>`.

26 *Constraints*: `is_constructible_v<T, decltype((val))>` is `true`.

27 *Mandates*: `G` is a valid template argument for `unexpected` (22.8.3.1) and the declaration

```
G g(invoke(std::forward<F>(f), error()));
```

is well-formed.

28 *Returns*: If `has_value()` is `true`, `expected<T, G>(in_place, val)`; otherwise, an `expected<T, G>` object whose *`has_val`* member is `false` and *`unex`* member is direct-non-list-initialized with `invoke(std::forward<F>(f), error())`.

```
template<class F> constexpr auto transform_error(F&& f) &&;
template<class F> constexpr auto transform_error(F&& f) const &&;
```

29 Let `G` be `remove_cv_t<invoke_result_t<F, decltype(std::move(error()))>>`.

30 *Constraints*: `is_constructible_v<T, decltype(std::move(val))>` is `true`.

31 *Mandates*: `G` is a valid template argument for `unexpected` (22.8.3.1) and the declaration

```
G g(invoke(std::forward<F>(f), std::move(error())));
```

is well-formed.

32 *Returns*: If `has_value()` is `true`, `expected<T, G>(in_place, std::move(val))`; otherwise, an `expected<T, G>` object whose *`has_val`* member is `false` and *`unex`* member is direct-non-list-initialized with `invoke(std::forward<F>(f), std::move(error()))`.

22.8.6.8 Equality operators [expected.object.eq]

```
template<class T2, class E2> requires (!is_void_v<T2>)
  friend constexpr bool operator==(const expected& x, const expected<T2, E2>& y);
```

1 *Constraints*: The expressions `*x == *y` and `x.error() == y.error()` are well-formed and their results are convertible to `bool`.

2 *Returns*: If `x.has_value()` does not equal `y.has_value()`, `false`; otherwise if `x.has_value()` is `true`, `*x == *y`; otherwise `x.error() == y.error()`.

```
template<class T2> friend constexpr bool operator==(const expected& x, const T2& v);
```

3 *Constraints*: `T2` is not a specialization of `expected`. The expression `*x == v` is well-formed and its result is convertible to `bool`.

[*Note 1*: `T` need not be *Cpp17EqualityComparable*. — *end note*]

4 *Returns*: If `x.has_value()` is `true`, `*x == v`; otherwise `false`.

```
template<class E2> friend constexpr bool operator==(const expected& x, const unexpected<E2>& e);
```

5 *Constraints*: The expression `x.error() == e.error()` is well-formed and its result is convertible to `bool`.

6 *Returns*: If `!x.has_value()` is `true`, `x.error() == e.error()`; otherwise `false`.

22.8.7 Partial specialization of `expected` for `void` types [expected.void]

22.8.7.1 General [expected.void.general]

```
template<class T, class E> requires is_void_v<T>
class expected<T, E> {
public:
  using value_type = T;
  using error_type = E;
  using unexpected_type = unexpected<E>;

  template<class U>
  using rebind = expected<U, error_type>;

  // 22.8.7.2, constructors
  constexpr expected() noexcept;
  constexpr expected(const expected&);
  constexpr expected(expected&&) noexcept(see below);
  template<class U, class G>
    constexpr explicit(see below) expected(const expected<U, G>&);
  template<class U, class G>
    constexpr explicit(see below) expected(expected<U, G>&&);

  template<class G>
    constexpr explicit(see below) expected(const unexpected<G>&);
  template<class G>
    constexpr explicit(see below) expected(unexpected<G>&&);

  constexpr explicit expected(in_place_t) noexcept;
  template<class... Args>
    constexpr explicit expected(unexpect_t, Args&&...);
  template<class U, class... Args>
    constexpr explicit expected(unexpect_t, initializer_list<U>, Args&&...);

  // 22.8.7.3, destructor
  constexpr ~expected();

  // 22.8.7.4, assignment
  constexpr expected& operator=(const expected&);
  constexpr expected& operator=(expected&&) noexcept(see below);
  template<class G>
    constexpr expected& operator=(const unexpected<G>&);
  template<class G>
    constexpr expected& operator=(unexpected<G>&&);
  constexpr void emplace() noexcept;

  // 22.8.7.5, swap
  constexpr void swap(expected&) noexcept(see below);
  friend constexpr void swap(expected& x, expected& y) noexcept(noexcept(x.swap(y)));

  // 22.8.7.6, observers
  constexpr explicit operator bool() const noexcept;
```

```
    constexpr bool has_value() const noexcept;
    constexpr void operator*() const noexcept;
    constexpr void value() const &;                                  // freestanding-deleted
    constexpr void value() &&;                                       // freestanding-deleted
    constexpr const E& error() const & noexcept;
    constexpr E& error() & noexcept;
    constexpr const E&& error() const && noexcept;
    constexpr E&& error() && noexcept;
    template<class G = E> constexpr E error_or(G&&) const &;
    template<class G = E> constexpr E error_or(G&&) &&;

    // 22.8.7.7, monadic operations
    template<class F> constexpr auto and_then(F&& f) &;
    template<class F> constexpr auto and_then(F&& f) &&;
    template<class F> constexpr auto and_then(F&& f) const &;
    template<class F> constexpr auto and_then(F&& f) const &&;
    template<class F> constexpr auto or_else(F&& f) &;
    template<class F> constexpr auto or_else(F&& f) &&;
    template<class F> constexpr auto or_else(F&& f) const &;
    template<class F> constexpr auto or_else(F&& f) const &&;
    template<class F> constexpr auto transform(F&& f) &;
    template<class F> constexpr auto transform(F&& f) &&;
    template<class F> constexpr auto transform(F&& f) const &;
    template<class F> constexpr auto transform(F&& f) const &&;
    template<class F> constexpr auto transform_error(F&& f) &;
    template<class F> constexpr auto transform_error(F&& f) &&;
    template<class F> constexpr auto transform_error(F&& f) const &;
    template<class F> constexpr auto transform_error(F&& f) const &&;

    // 22.8.7.8, equality operators
    template<class T2, class E2> requires is_void_v<T2>
      friend constexpr bool operator==(const expected& x, const expected<T2, E2>& y);
    template<class E2>
      friend constexpr bool operator==(const expected&, const unexpected<E2>&);

  private:
    bool has_val;          // exposition only
    union {
      E unex;              // exposition only
    };
  };
```

1 Any object of type `expected<T, E>` either represents a value of type `T`, or contains a value of type `E` nested within (6.8.2) it. Member *`has_val`* indicates whether the `expected<T, E>` object represents a value of type `T`.

2 A program that instantiates the definition of the template `expected<T, E>` with a type for the `E` parameter that is not a valid template argument for `unexpected` is ill-formed.

3 `E` shall meet the requirements of *Cpp17Destructible* (Table 35).

22.8.7.2 Constructors [expected.void.cons]

```
constexpr expected() noexcept;
```

1 *Postconditions*: `has_value()` is `true`.

```
constexpr expected(const expected& rhs);
```

2 *Effects*: If `rhs.has_value()` is `false`, direct-non-list-initializes *`unex`* with `rhs.error()`.

3 *Postconditions*: `rhs.has_value() == this->has_value()`.

4 *Throws*: Any exception thrown by the initialization of *`unex`*.

5 *Remarks*: This constructor is defined as deleted unless `is_copy_constructible_v<E>` is `true`.

6 This constructor is trivial if `is_trivially_copy_constructible_v<E>` is `true`.

```
constexpr expected(expected&& rhs) noexcept(is_nothrow_move_constructible_v<E>);
```

7 *Constraints*: `is_move_constructible_v<E>` is `true`.

8 *Effects*: If `rhs.has_value()` is `false`, direct-non-list-initializes *unex* with `std::move(rhs.error())`.

9 *Postconditions*: `rhs.has_value()` is unchanged; `rhs.has_value() == this->has_value()` is `true`.

10 *Throws*: Any exception thrown by the initialization of *unex*.

11 *Remarks*: This constructor is trivial if `is_trivially_move_constructible_v<E>` is `true`.

```
template<class U, class G>
  constexpr explicit(!is_convertible_v<const G&, E>) expected(const expected<U, G>& rhs);
template<class U, class G>
  constexpr explicit(!is_convertible_v<G, E>) expected(expected<U, G>&& rhs);
```

12 Let `GF` be `const G&` for the first overload and `G` for the second overload.

13 *Constraints*:

(13.1) — `is_void_v<U>` is `true`; and

(13.2) — `is_constructible_v<E, GF>` is `true`; and

(13.3) — `is_constructible_v<unexpected<E>, expected<U, G>&>` is `false`; and

(13.4) — `is_constructible_v<unexpected<E>, expected<U, G>>` is `false`; and

(13.5) — `is_constructible_v<unexpected<E>, const expected<U, G>&>` is `false`; and

(13.6) — `is_constructible_v<unexpected<E>, const expected<U, G>>` is `false`.

14 *Effects*: If `rhs.has_value()` is `false`, direct-non-list-initializes *unex* with `std::forward<GF>(rhs.error())`.

15 *Postconditions*: `rhs.has_value()` is unchanged; `rhs.has_value() == this->has_value()` is `true`.

16 *Throws*: Any exception thrown by the initialization of *unex*.

```
template<class G>
  constexpr explicit(!is_convertible_v<const G&, E>) expected(const unexpected<G>& e);
template<class G>
  constexpr explicit(!is_convertible_v<G, E>) expected(unexpected<G>&& e);
```

17 Let `GF` be `const G&` for the first overload and `G` for the second overload.

18 *Constraints*: `is_constructible_v<E, GF>` is `true`.

19 *Effects*: Direct-non-list-initializes *unex* with `std::forward<GF>(e.error())`.

20 *Postconditions*: `has_value()` is `false`.

21 *Throws*: Any exception thrown by the initialization of *unex*.

```
constexpr explicit expected(in_place_t) noexcept;
```

22 *Postconditions*: `has_value()` is `true`.

```
template<class... Args>
  constexpr explicit expected(unexpect_t, Args&&... args);
```

23 *Constraints*: `is_constructible_v<E, Args...>` is `true`.

24 *Effects*: Direct-non-list-initializes *unex* with `std::forward<Args>(args)...`.

25 *Postconditions*: `has_value()` is `false`.

26 *Throws*: Any exception thrown by the initialization of *unex*.

```
template<class U, class... Args>
  constexpr explicit expected(unexpect_t, initializer_list<U> il, Args&&... args);
```

27 *Constraints*: `is_constructible_v<E, initializer_list<U>&, Args...>` is `true`.

28 *Effects*: Direct-non-list-initializes *unex* with `il, std::forward<Args>(args)...`.

29 *Postconditions*: `has_value()` is `false`.

30 *Throws*: Any exception thrown by the initialization of *unex*.

22.8.7.3 Destructor [expected.void.dtor]

```
constexpr ~expected();
```

1 *Effects*: If `has_value()` is `false`, destroys *unex*.

2 *Remarks*: If `is_trivially_destructible_v<E>` is `true`, then this destructor is a trivial destructor.

22.8.7.4 Assignment [expected.void.assign]

```
constexpr expected& operator=(const expected& rhs);
```

1 *Effects*:

(1.1) — If `this->has_value() && rhs.has_value()` is `true`, no effects.

(1.2) — Otherwise, if `this->has_value()` is `true`, equivalent to: `construct_at(addressof(`*unex*`), rhs.`*unex*`); `*has_val*` = false;`

(1.3) — Otherwise, if `rhs.has_value()` is `true`, destroys *unex* and sets *has_val* to `true`.

(1.4) — Otherwise, equivalent to *unex* `= rhs.error()`.

2 *Returns*: `*this`.

3 *Remarks*: This operator is defined as deleted unless `is_copy_assignable_v<E>` is `true` and `is_copy_constructible_v<E>` is `true`.

4 This operator is trivial if `is_trivially_copy_constructible_v<E>`, `is_trivially_copy_assignable_v<E>`, and `is_trivially_destructible_v<E>` are all `true`.

```
constexpr expected& operator=(expected&& rhs) noexcept(see below);
```

5 *Constraints*: `is_move_constructible_v<E>` is `true` and `is_move_assignable_v<E>` is `true`.

6 *Effects*:

(6.1) — If `this->has_value() && rhs.has_value()` is `true`, no effects.

(6.2) — Otherwise, if `this->has_value()` is `true`, equivalent to:

```
construct_at(addressof(unex), std::move(rhs.unex));
has_val = false;
```

(6.3) — Otherwise, if `rhs.has_value()` is `true`, destroys *unex* and sets *has_val* to `true`.

(6.4) — Otherwise, equivalent to *unex* `= std::move(rhs.error())`.

7 *Returns*: `*this`.

8 *Remarks*: The exception specification is equivalent to `is_nothrow_move_constructible_v<E> && is_nothrow_move_assignable_v<E>`.

9 This operator is trivial if `is_trivially_move_constructible_v<E>`, `is_trivially_move_assignable_v<E>`, and `is_trivially_destructible_v<E>` are all `true`.

```
template<class G>
  constexpr expected& operator=(const unexpected<G>& e);
template<class G>
  constexpr expected& operator=(unexpected<G>&& e);
```

10 Let `GF` be `const G&` for the first overload and `G` for the second overload.

11 *Constraints*: `is_constructible_v<E, GF>` is `true` and `is_assignable_v<E&, GF>` is `true`.

12 *Effects*:

(12.1) — If `has_value()` is `true`, equivalent to:

```
construct_at(addressof(unex), std::forward<GF>(e.error()));
has_val = false;
```

(12.2) — Otherwise, equivalent to: *unex* `= std::forward<GF>(e.error());`

13 *Returns*: `*this`.

```
constexpr void emplace() noexcept;
```

14 *Effects*: If `has_value()` is `false`, destroys *unex* and sets *has_val* to `true`.

22.8.7.5 Swap [expected.void.swap]

```
constexpr void swap(expected& rhs) noexcept(see below);
```

1 *Constraints*: `is_swappable_v<E>` is `true` and `is_move_constructible_v<E>` is `true`.

2 *Effects*: See Table 73.

Table 73 — `swap(expected&)` effects [tab:expected.void.swap]

	`this->has_value()`	`!this->has_value()`
`rhs.has_value()`	no effects	calls `rhs.swap(*this)`
`!rhs.has_value()`	*see below*	equivalent to: `using std::swap;` `swap(`*unex*`, rhs.`*unex*`);`

For the case where `rhs.has_value()` is `false` and `this->has_value()` is `true`, equivalent to:

```
construct_at(addressof(unex), std::move(rhs.unex));
destroy_at(addressof(rhs.unex));
has_val = false;
rhs.has_val = true;
```

3 *Throws*: Any exception thrown by the expressions in the *Effects*.

4 *Remarks*: The exception specification is equivalent to `is_nothrow_move_constructible_v<E> && is_nothrow_swappable_v<E>`.

```
friend constexpr void swap(expected& x, expected& y) noexcept(noexcept(x.swap(y)));
```

5 *Effects*: Equivalent to `x.swap(y)`.

22.8.7.6 Observers [expected.void.obs]

```
constexpr explicit operator bool() const noexcept;
constexpr bool has_value() const noexcept;
```

1 *Returns*: *has_val*.

```
constexpr void operator*() const noexcept;
```

2 *Hardened preconditions*: `has_value()` is `true`.

```
constexpr void value() const &;
```

3 *Mandates*: `is_copy_constructible_v<E>` is `true`.

4 *Throws*: `bad_expected_access(error())` if `has_value()` is `false`.

```
constexpr void value() &&;
```

5 *Mandates*: `is_copy_constructible_v<E>` is `true` and `is_move_constructible_v<E>` is `true`.

6 *Throws*: `bad_expected_access(std::move(error()))` if `has_value()` is `false`.

```
constexpr const E& error() const & noexcept;
constexpr E& error() & noexcept;
```

7 *Hardened preconditions*: `has_value()` is `false`.

8 *Returns*: *unex*.

```
constexpr E&& error() && noexcept;
constexpr const E&& error() const && noexcept;
```

9 *Hardened preconditions*: `has_value()` is `false`.

10 *Returns*: `std::move(`*unex*`)`.

```
template<class G = E> constexpr E error_or(G&& e) const &;
```

11 *Mandates*: `is_copy_constructible_v<E>` is `true` and `is_convertible_v<G, E>` is `true`.

12 *Returns*: `std::forward<G>(e)` if `has_value()` is `true`, `error()` otherwise.

```
template<class G = E> constexpr E error_or(G&& e) &&;
```

13 *Mandates*: `is_move_constructible_v<E>` is `true` and `is_convertible_v<G, E>` is `true`.

14 *Returns*: `std::forward<G>(e)` if `has_value()` is `true`, `std::move(error())` otherwise.

22.8.7.7 Monadic operations [expected.void.monadic]

```
template<class F> constexpr auto and_then(F&& f) &;
template<class F> constexpr auto and_then(F&& f) const &;
```

1 Let `U` be `remove_cvref_t<invoke_result_t<F>>`.

2 *Constraints*: `is_constructible_v<E, decltype(error())>>` is `true`.

3 *Mandates*: `U` is a specialization of `expected` and `is_same_v<typename U::error_type, E>` is `true`.

4 *Effects*: Equivalent to:

```
if (has_value())
  return invoke(std::forward<F>(f));
else
  return U(unexpect, error());
```

```
template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &&;
```

5 Let `U` be `remove_cvref_t<invoke_result_t<F>>`.

6 *Constraints*: `is_constructible_v<E, decltype(std::move(error()))>` is `true`.

7 *Mandates*: `U` is a specialization of `expected` and `is_same_v<typename U::error_type, E>` is `true`.

8 *Effects*: Equivalent to:

```
if (has_value())
  return invoke(std::forward<F>(f));
else
  return U(unexpect, std::move(error()));
```

```
template<class F> constexpr auto or_else(F&& f) &;
template<class F> constexpr auto or_else(F&& f) const &;
```

9 Let `G` be `remove_cvref_t<invoke_result_t<F, decltype(error())>>`.

10 *Mandates*: `G` is a specialization of `expected` and `is_same_v<typename G::value_type, T>` is `true`.

11 *Effects*: Equivalent to:

```
if (has_value())
  return G();
else
  return invoke(std::forward<F>(f), error());
```

```
template<class F> constexpr auto or_else(F&& f) &&;
template<class F> constexpr auto or_else(F&& f) const &&;
```

12 Let `G` be `remove_cvref_t<invoke_result_t<F, decltype(std::move(error()))>>`.

13 *Mandates*: `G` is a specialization of `expected` and `is_same_v<typename G::value_type, T>` is `true`.

14 *Effects*: Equivalent to:

```
if (has_value())
  return G();
else
  return invoke(std::forward<F>(f), std::move(error()));
```

```
template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) const &;
```

15 Let `U` be `remove_cv_t<invoke_result_t<F>>`.

16 *Constraints*: `is_constructible_v<E, decltype(error())>` is `true`.

17 *Mandates*: `U` is a valid value type for `expected`. If `is_void_v<U>` is `false`, the declaration

```
U u(invoke(std::forward<F>(f)));
```

is well-formed.

18 *Effects*:

(18.1) — If `has_value()` is `false`, returns `expected<U, E>(unexpect, error())`.

(18.2) — Otherwise, if `is_void_v<U>` is `false`, returns an `expected<U, E>` object whose *`has_val`* member is `true` and *`val`* member is direct-non-list-initialized with `invoke(std::forward<F>(f))`.

(18.3) — Otherwise, evaluates `invoke(std::forward<F>(f))` and then returns `expected<U, E>()`.

```
template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) const &;
```

19 Let `U` be `remove_cv_t<invoke_result_t<F>>`.

20 *Constraints*: `is_constructible_v<E, decltype(std::move(error()))>` is `true`.

21 *Mandates*: `U` is a valid value type for `expected`. If `is_void_v<U>` is `false`, the declaration

```
U u(invoke(std::forward<F>(f)));
```

is well-formed.

22 *Effects*:

(22.1) — If `has_value()` is `false`, returns `expected<U, E>(unexpect, std::move(error()))`.

(22.2) — Otherwise, if `is_void_v<U>` is `false`, returns an `expected<U, E>` object whose *`has_val`* member is `true` and *`val`* member is direct-non-list-initialized with `invoke(std::forward<F>(f))`.

(22.3) — Otherwise, evaluates `invoke(std::forward<F>(f))` and then returns `expected<U, E>()`.

```
template<class F> constexpr auto transform_error(F&& f) &;
template<class F> constexpr auto transform_error(F&& f) const &;
```

23 Let `G` be `remove_cv_t<invoke_result_t<F, decltype(error())>>`.

24 *Mandates*: `G` is a valid template argument for `unexpected` (22.8.3.1) and the declaration

```
G g(invoke(std::forward<F>(f), error()));
```

is well-formed.

25 *Returns*: If `has_value()` is `true`, `expected<T, G>()`; otherwise, an `expected<T, G>` object whose *`has_val`* member is `false` and *`unex`* member is direct-non-list-initialized with `invoke(std::forward<F>(f), error())`.

```
template<class F> constexpr auto transform_error(F&& f) &&;
template<class F> constexpr auto transform_error(F&& f) const &&;
```

26 Let `G` be `remove_cv_t<invoke_result_t<F, decltype(std::move(error()))>>`.

27 *Mandates*: `G` is a valid template argument for `unexpected` (22.8.3.1) and the declaration

```
G g(invoke(std::forward<F>(f), std::move(error())));
```

is well-formed.

28 *Returns*: If `has_value()` is `true`, `expected<T, G>()`; otherwise, an `expected<T, G>` object whose *`has_val`* member is `false` and *`unex`* member is direct-non-list-initialized with `invoke(std::forward<F>(f), std::move(error()))`.

22.8.7.8 Equality operators [expected.void.eq]

```
template<class T2, class E2> requires is_void_v<T2>
  friend constexpr bool operator==(const expected& x, const expected<T2, E2>& y);
```

1 *Constraints*: The expression `x.error() == y.error()` is well-formed and its result is convertible to `bool`.

2 *Returns*: If `x.has_value()` does not equal `y.has_value()`, `false`; otherwise if `x.has_value()` is `true`, `true`; otherwise `x.error() == y.error()`.

```
template<class E2>
  friend constexpr bool operator==(const expected& x, const unexpected<E2>& e);
```

3 *Constraints*: The expression `x.error() == e.error()` is well-formed and its result is convertible to `bool`.

4 *Returns*: If `!x.has_value()` is `true`, `x.error() == e.error()`; otherwise `false`.

22.9 Bitsets [bitset]

22.9.1 Header <bitset> synopsis [bitset.syn]

1 The header `<bitset>` defines a class template and several related functions for representing and manipulating fixed-size sequences of bits.

```
#include <string>    // see 27.4.2
#include <iosfwd>    // for istream (31.7.1), ostream (31.7.2), see 31.3.1

namespace std {
  template<size_t N> class bitset;

  // 22.9.4, bitset operators
  template<size_t N>
    constexpr bitset<N> operator&(const bitset<N>&, const bitset<N>&) noexcept;
  template<size_t N>
    constexpr bitset<N> operator|(const bitset<N>&, const bitset<N>&) noexcept;
  template<size_t N>
    constexpr bitset<N> operator^(const bitset<N>&, const bitset<N>&) noexcept;
  template<class charT, class traits, size_t N>
    basic_istream<charT, traits>&
      operator>>(basic_istream<charT, traits>& is, bitset<N>& x);
  template<class charT, class traits, size_t N>
    basic_ostream<charT, traits>&
      operator<<(basic_ostream<charT, traits>& os, const bitset<N>& x);
}
```

22.9.2 Class template bitset [template.bitset]

22.9.2.1 General [template.bitset.general]

```
namespace std {
  template<size_t N> class bitset {
  public:
    // bit reference
    class reference {
    public:
      constexpr reference(const reference& x) noexcept;
      constexpr ~reference();
      constexpr reference& operator=(bool x) noexcept;                // for b[i] = x;

  constexpr bool none() const noexcept;
};

// 22.9.3, hash support
template<class T> struct hash;
template<size_t N> struct hash<bitset<N>>;
}
```

[1] The class template `bitset<N>` describes an object that can store a sequence consisting of a fixed number of bits, `N`.

2 Each bit represents either the value zero (reset) or one (set). To *toggle* a bit is to change the value zero to one, or the value one to zero. Each bit has a non-negative position `pos`. When converting between an object of type `bitset<N>` and a value of some integral type, bit position `pos` corresponds to the *bit value* `1 << pos`. The integral value corresponding to two or more bits is the sum of their bit values.

3 `reference` is a class that simulates a reference to a single bit in the sequence.

```
constexpr reference::reference(const reference& x) noexcept;
```

4 *Effects*: Initializes `*this` to refer to the same bit as `x`.

```
constexpr reference::~reference();
```

5 *Effects*: None.

```
constexpr reference& reference::operator=(bool x) noexcept;
constexpr reference& reference::operator=(const reference& x) noexcept;
constexpr const reference& reference::operator=(bool x) const noexcept;
```

6 *Effects*: Sets the bit referred to by `*this` if `bool(x)` is `true`, and clears it otherwise.

7 *Returns*: `*this`.

```
constexpr reference::operator bool() const noexcept;
```

8 *Returns*: `true` if the value of the bit referred to by `*this` is one, `false` otherwise.

```
constexpr bool reference::operator~() const noexcept;
```

9 *Returns*: `!bool(*this)`.

```
constexpr void swap(reference x, reference y) noexcept;
constexpr void swap(reference x, bool& y) noexcept;
constexpr void swap(bool& x, reference y) noexcept;
```

10 *Effects*: Exchanges the values denoted by `x` and `y` as if by:

```
bool b = x;
x = y;
y = b;
```

```
constexpr reference& reference::flip() noexcept;
```

11 *Effects*: Equivalent to `*this = !*this`.

12 *Returns*: `*this`.

13 The functions described in 22.9.2 can report three kinds of errors, each associated with a distinct exception:

(13.1) — an *invalid-argument* error is associated with exceptions of type `invalid_argument` (19.2.5);

(13.2) — an *out-of-range* error is associated with exceptions of type `out_of_range` (19.2.7);

(13.3) — an *overflow* error is associated with exceptions of type `overflow_error` (19.2.10).

22.9.2.2 Constructors [bitset.cons]

```
constexpr bitset() noexcept;
```

1 *Effects*: Initializes all bits in `*this` to zero.

```
constexpr bitset(unsigned long long val) noexcept;
```

2 *Effects*: Initializes the first `M` bit positions to the corresponding bit values in `val`. `M` is the smaller of `N` and the number of bits in the value representation (6.9.1) of `unsigned long long`. If `M < N`, the remaining bit positions are initialized to zero.

```
template<class charT, class traits, class Allocator>
  constexpr explicit bitset(
    const basic_string<charT, traits, Allocator>& str,
    typename basic_string<charT, traits, Allocator>::size_type pos = 0,
    typename basic_string<charT, traits, Allocator>::size_type n
      = basic_string<charT, traits, Allocator>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));
```

```
template<class charT, class traits>
  constexpr explicit bitset(
    basic_string_view<charT, traits> str,
    typename basic_string_view<charT, traits>::size_type pos = 0,
    typename basic_string_view<charT, traits>::size_type n
      = basic_string_view<charT, traits>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));
```

3 *Effects*: Determines the effective length `rlen` of the initializing string as the smaller of `n` and `str.size() - pos`. Initializes the first `M` bit positions to values determined from the corresponding characters in the string `str`. `M` is the smaller of `N` and `rlen`.

4 An element of the constructed object has value zero if the corresponding character in `str`, beginning at position `pos`, is `zero`. Otherwise, the element has the value one. Character position `pos + M - 1` corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions.

5 If `M < N`, remaining bit positions are initialized to zero.

6 The function uses `traits::eq` to compare the character values.

7 *Throws*: `out_of_range` if `pos > str.size()` or `invalid_argument` if any of the `rlen` characters in `str` beginning at position `pos` is other than `zero` or `one`.

```
template<class charT>
  constexpr explicit bitset(
    const charT* str,
    typename basic_string_view<charT>::size_type n = basic_string_view<charT>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));
```

8 *Constraints*:

(8.1) — `is_array_v<charT>` is `false`,

(8.2) — `is_trivially_copyable_v<charT>` is `true`,

(8.3) — `is_standard_layout_v<charT>` is `true`, and

(8.4) — `is_trivially_default_constructible_v<charT>` is `true`.

9 *Effects*: As if by:

```
bitset(n == basic_string_view<charT>::npos
          ? basic_string_view<charT>(str)
          : basic_string_view<charT>(str, n),
       0, n, zero, one)
```

22.9.2.3 Members [bitset.members]

```
constexpr bitset& operator&=(const bitset& rhs) noexcept;
```

1 *Effects*: Clears each bit in `*this` for which the corresponding bit in `rhs` is clear, and leaves all other bits unchanged.

2 *Returns*: `*this`.

```
constexpr bitset& operator|=(const bitset& rhs) noexcept;
```

3 *Effects*: Sets each bit in `*this` for which the corresponding bit in `rhs` is set, and leaves all other bits unchanged.

4 *Returns*: `*this`.

```
constexpr bitset& operator^=(const bitset& rhs) noexcept;
```

5 *Effects*: Toggles each bit in `*this` for which the corresponding bit in `rhs` is set, and leaves all other bits unchanged.

6 *Returns*: `*this`.

```
constexpr bitset& operator<<=(size_t pos) noexcept;
```

7 *Effects*: Replaces each bit at position `I` in `*this` with a value determined as follows:

(7.1) — If `I < pos`, the new value is zero;

(7.2) — If `I >= pos`, the new value is the previous value of the bit at position `I - pos`.

8 *Returns*: `*this`.

```
constexpr bitset& operator>>=(size_t pos) noexcept;
```

9 *Effects*: Replaces each bit at position `I` in `*this` with a value determined as follows:

(9.1) — If `pos >= N - I`, the new value is zero;

(9.2) — If `pos < N - I`, the new value is the previous value of the bit at position `I + pos`.

10 *Returns*: `*this`.

```
constexpr bitset operator<<(size_t pos) const noexcept;
```

11 *Returns*: `bitset(*this) <<= pos`.

```
constexpr bitset operator>>(size_t pos) const noexcept;
```

12 *Returns*: `bitset(*this) >>= pos`.

```
constexpr bitset& set() noexcept;
```

13 *Effects*: Sets all bits in `*this`.

14 *Returns*: `*this`.

```
constexpr bitset& set(size_t pos, bool val = true);
```

15 *Effects*: Stores a new value in the bit at position `pos` in `*this`. If `val` is `true`, the stored value is one, otherwise it is zero.

16 *Returns*: `*this`.

17 *Throws*: `out_of_range` if `pos` does not correspond to a valid bit position.

```
constexpr bitset& reset() noexcept;
```

18 *Effects*: Resets all bits in `*this`.

19 *Returns*: `*this`.

```
constexpr bitset& reset(size_t pos);
```

20 *Effects*: Resets the bit at position `pos` in `*this`.

21 *Returns*: `*this`.

22 *Throws*: `out_of_range` if `pos` does not correspond to a valid bit position.

```
constexpr bitset operator~() const noexcept;
```

23 *Effects*: Constructs an object `x` of class `bitset` and initializes it with `*this`.

24 *Returns*: `x.flip()`.

```
constexpr bitset& flip() noexcept;
```

25 *Effects*: Toggles all bits in `*this`.

26 *Returns*: `*this`.

```
constexpr bitset& flip(size_t pos);
```

27 *Effects*: Toggles the bit at position `pos` in `*this`.

28 *Returns*: `*this`.

29 *Throws*: `out_of_range` if `pos` does not correspond to a valid bit position.

```
constexpr bool operator[](size_t pos) const;
```

30 *Hardened preconditions*: `pos < size()` is `true`.

31 *Returns*: `true` if the bit at position `pos` in `*this` has the value one, otherwise `false`.

32 *Throws*: Nothing.

```
constexpr bitset::reference operator[](size_t pos);
```

33 *Hardened preconditions*: `pos < size()` is `true`.

34 *Returns*: An object of type `bitset::reference` such that `(*this)[pos] == this->test(pos)`, and such that `(*this)[pos] = val` is equivalent to `this->set(pos, val)`.

35 *Throws*: Nothing.

36 *Remarks*: For the purpose of determining the presence of a data race (6.10.2), any access or update through the resulting reference potentially accesses or modifies, respectively, the entire underlying bitset.

```
constexpr unsigned long to_ulong() const;
```

37 *Returns*: `x`.

38 *Throws*: `overflow_error` if the integral value `x` corresponding to the bits in `*this` cannot be represented as type `unsigned long`.

```
constexpr unsigned long long to_ullong() const;
```

39 *Returns*: `x`.

40 *Throws*: `overflow_error` if the integral value `x` corresponding to the bits in `*this` cannot be represented as type `unsigned long long`.

```
template<class charT = char,
         class traits = char_traits<charT>,
         class Allocator = allocator<charT>>
  constexpr basic_string<charT, traits, Allocator>
    to_string(charT zero = charT('0'), charT one = charT('1')) const;
```

41 *Effects*: Constructs a string object of the appropriate type and initializes it to a string of length `N` characters. Each character is determined by the value of its corresponding bit position in `*this`. Character position `N - 1` corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions. Bit value zero becomes the character `zero`, bit value one becomes the character `one`.

42 *Returns*: The created object.

```
constexpr size_t count() const noexcept;
```

43 *Returns*: A count of the number of bits set in `*this`.

```
constexpr size_t size() const noexcept;
```

44 *Returns*: `N`.

```
constexpr bool operator==(const bitset& rhs) const noexcept;
```

45 *Returns*: `true` if the value of each bit in `*this` equals the value of the corresponding bit in `rhs`.

```
constexpr bool test(size_t pos) const;
```

46 *Returns*: `true` if the bit at position `pos` in `*this` has the value one.

47 *Throws*: `out_of_range` if `pos` does not correspond to a valid bit position.

```
constexpr bool all() const noexcept;
```

48 *Returns*: `count() == size()`.

```
constexpr bool any() const noexcept;
```

49 *Returns*: `count() != 0`.

```
constexpr bool none() const noexcept;
```

50 *Returns*: `count() == 0`.

22.9.3 `bitset` hash support [bitset.hash]

```
template<size_t N> struct hash<bitset<N>>;
```

1 The specialization is enabled (22.10.19).

22.9.4 `bitset` operators [bitset.operators]

```
template<size_t N>
  constexpr bitset<N> operator&(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;
```

1 *Returns*: `bitset<N>(lhs) &= rhs`.

```
template<size_t N>
  constexpr bitset<N> operator|(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;
```

2 *Returns*: `bitset<N>(lhs) |= rhs`.

```
template<size_t N>
  constexpr bitset<N> operator^(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;
```

3 *Returns*: `bitset<N>(lhs) ^= rhs`.

```
template<class charT, class traits, size_t N>
  basic_istream<charT, traits>&
    operator>>(basic_istream<charT, traits>& is, bitset<N>& x);
```

4 A formatted input function (31.7.5.3).

5 *Effects*: Extracts up to `N` characters from `is`. Stores these characters in a temporary object `str` of type `basic_string<charT, traits>`, then evaluates the expression `x = bitset<N>(str)`. Characters are extracted and stored until any of the following occurs:

(5.1) — `N` characters have been extracted and stored;

(5.2) — end-of-file occurs on the input sequence;

(5.3) — the next input character is neither `is.widen('0')` nor `is.widen('1')` (in which case the input character is not extracted).

6 If `N > 0` and no characters are stored in `str`, `ios_base::failbit` is set in the input function's local error state before `setstate` is called.

7 *Returns*: `is`.

```
template<class charT, class traits, size_t N>
  basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const bitset<N>& x);
```

8 *Returns*:

```
os << x.template to_string<charT, traits, allocator<charT>>(
  use_facet<ctype<charT>>(os.getloc()).widen('0'),
  use_facet<ctype<charT>>(os.getloc()).widen('1'))
```

(see 31.7.6.3).

22.10 Function objects [function.objects]

22.10.1 General [function.objects.general]

1 A *function object type* is an object type (6.9.1) that can be the type of the *postfix-expression* in a function call (7.6.1.3, 12.2.2.2).[173] A *function object* is an object of a function object type. In the places where one would expect to pass a pointer to a function to an algorithmic template (Clause 26), the interface is specified to accept a function object. This not only makes algorithmic templates work with pointers to functions, but also enables them to work with arbitrary function objects.

22.10.2 Header `<functional>` synopsis [functional.syn]

```
#include <initializer_list>     // see 17.11.2
#include <typeinfo>             // see 17.7.2
```

173) Such a type is a function pointer or a class type which has a member `operator()` or a class type which has a conversion to a pointer to function.

```
namespace std {
  // 22.10.5, invoke
  template<class F, class... Args>
    constexpr invoke_result_t<F, Args...> invoke(F&& f, Args&&... args)              // freestanding
      noexcept(is_nothrow_invocable_v<F, Args...>);

  template<class R, class F, class... Args>
    constexpr R invoke_r(F&& f, Args&&... args)                                      // freestanding
      noexcept(is_nothrow_invocable_r_v<R, F, Args...>);

  // 22.10.6, reference_wrapper
  template<class T> class reference_wrapper;                                         // freestanding

  struct less_equal;                                                                        // freestanding
}

template<class Fn, class... Args>
  concept callable =                                                    // exposition only
    requires (Fn&& fn, Args&&... args) {
      std::forward<Fn>(fn)(std::forward<Args>(args)...);
    };
```

```
  template<class Fn, class... Args>
    concept nothrow-callable =                                    // exposition only
      callable<Fn, Args...> &&
      requires (Fn&& fn, Args&&... args) {
        { std::forward<Fn>(fn)(std::forward<Args>(args)...) } noexcept;
      };

  template<class Fn, class... Args>
    using call-result-t = decltype(declval<Fn>()(declval<Args>()...));  // exposition only

  template<const auto& T>
    using decayed-typeof = decltype(auto(T));                     // exposition only
}
```

1 [*Example 1*: If a C++ program wants to have a by-element addition of two vectors `a` and `b` containing `double` and put the result into `a`, it can do:

```
transform(a.begin(), a.end(), b.begin(), a.begin(), plus<double>());
```

— *end example*]

2 [*Example 2*: To negate every element of `a`:

```
transform(a.begin(), a.end(), a.begin(), negate<double>());
```

— *end example*]

22.10.3 Definitions [func.def]

1 The following definitions apply to this Clause:

2 A *call signature* is the name of a return type followed by a parenthesized comma-separated list of zero or more argument types.

3 A *callable type* is a function object type (22.10) or a pointer to member.

4 A *callable object* is an object of a callable type.

5 A *call wrapper type* is a type that holds a *target object*, which is either a callable object or an object representing a callable object, and supports a call operation that forwards to that callable object.

6 A *call wrapper* is an object of a call wrapper type.

7 A call wrapper type may additionally hold a sequence of objects and references that may be passed as arguments to the callable object. These entities are collectively referred to as *bound argument entities*.

8 The target object and bound argument entities of the call wrapper are collectively referred to as *state entities*.

22.10.4 Requirements [func.require]

1 Define *INVOKE*(f, t_1, t_2, ..., t_N) as follows:

(1.1) — (t_1.*f)(t_2, ..., t_N) when f is a pointer to a member function of a class T and is_same_v<T, remove_cvref_t<decltype(t_1)>> || is_base_of_v<T, remove_cvref_t<decltype(t_1)>> is true;

(1.2) — (t_1.get().*f)(t_2, ..., t_N) when f is a pointer to a member function of a class T and remove_cvref_t<decltype(t_1)> is a specialization of reference_wrapper;

(1.3) — ((*t_1).*f)(t_2, ..., t_N) when f is a pointer to a member function of a class T and t_1 does not satisfy the previous two items;

(1.4) — t_1.*f when $N = 1$ and f is a pointer to data member of a class T and is_same_v<T, remove_cvref_t<decltype(t_1)>> || is_base_of_v<T, remove_cvref_t<decltype(t_1)>> is true;

(1.5) — t_1.get().*f when $N = 1$ and f is a pointer to data member of a class T and remove_cvref_t<decltype(t_1)> is a specialization of reference_wrapper;

(1.6) — (*t_1).*f when $N = 1$ and f is a pointer to data member of a class T and t_1 does not satisfy the previous two items;

(1.7) — f(t_1, t_2, ..., t_N) in all other cases.

2 Define *INVOKE*<R>(f, t_1, t_2, ..., t_N) as static_cast<void>(*INVOKE*(f, t_1, t_2, ..., t_N)) if R is *cv* void, otherwise *INVOKE*(f, t_1, t_2, ..., t_N) implicitly converted to R. If reference_converts_from_-

`temporary_v<R, decltype(`*INVOKE*`(f, t1, t2, ..., tN))>` is `true`, *INVOKE*`<R>(f, t1, t2, ..., tN)` is ill-formed.

3 Every call wrapper (22.10.3) meets the *Cpp17MoveConstructible* and *Cpp17Destructible* requirements. An *argument forwarding call wrapper* is a call wrapper that can be called with an arbitrary argument list and delivers the arguments to the target object as references. This forwarding step delivers rvalue arguments as rvalue references and lvalue arguments as lvalue references.

[*Note 1*: In a typical implementation, argument forwarding call wrappers have an overloaded function call operator of the form

```
template<class... UnBoundArgs>
  constexpr R operator()(UnBoundArgs&&... unbound_args) cv-qual ;
```

— *end note*]

4 A *perfect forwarding call wrapper* is an argument forwarding call wrapper that forwards its state entities to the underlying call expression. This forwarding step delivers a state entity of type `T` as *cv* `T&` when the call is performed on an lvalue of the call wrapper type and as *cv* `T&&` otherwise, where *cv* represents the cv-qualifiers of the call wrapper and where *cv* shall be neither `volatile` nor `const volatile`.

5 A *call pattern* defines the semantics of invoking a perfect forwarding call wrapper. A postfix call performed on a perfect forwarding call wrapper is expression-equivalent (3.22) to an expression `e` determined from its call pattern `cp` by replacing all occurrences of the arguments of the call wrapper and its state entities with references as described in the corresponding forwarding steps.

6 A *simple call wrapper* is a perfect forwarding call wrapper that meets the *Cpp17CopyConstructible* and *Cpp17CopyAssignable* requirements and whose copy constructor, move constructor, and assignment operators are constexpr functions that do not throw exceptions.

7 The copy/move constructor of an argument forwarding call wrapper has the same apparent semantics as if memberwise copy/move of its state entities were performed (11.4.5.3).

[*Note 2*: This implies that each of the copy/move constructors has the same exception-specification as the corresponding implicit definition and is declared as `constexpr` if the corresponding implicit definition would be considered to be constexpr. — *end note*]

8 Argument forwarding call wrappers returned by a given standard library function template have the same type if the types of their corresponding state entities are the same.

22.10.5 `invoke` functions [func.invoke]

```
template<class F, class... Args>
  constexpr invoke_result_t<F, Args...> invoke(F&& f, Args&&... args)
    noexcept(is_nothrow_invocable_v<F, Args...>);
```

1 *Constraints*: `is_invocable_v<F, Args...>` is `true`.

2 *Returns*: *INVOKE*`(std::forward<F>(f), std::forward<Args>(args)...)` (22.10.4).

```
template<class R, class F, class... Args>
  constexpr R invoke_r(F&& f, Args&&... args)
    noexcept(is_nothrow_invocable_r_v<R, F, Args...>);
```

3 *Constraints*: `is_invocable_r_v<R, F, Args...>` is `true`.

4 *Returns*: *INVOKE*`<R>(std::forward<F>(f), std::forward<Args>(args)...)` (22.10.4).

22.10.6 Class template `reference_wrapper` [refwrap]

22.10.6.1 General [refwrap.general]

```
namespace std {
  template<class T> class reference_wrapper {
  public:
    // types
    using type = T;

    // 22.10.6.2, constructors
    template<class U>
      constexpr reference_wrapper(U&&) noexcept(see below);
    constexpr reference_wrapper(const reference_wrapper& x) noexcept;
```

```
    // 22.10.6.3, assignment
    constexpr reference_wrapper& operator=(const reference_wrapper& x) noexcept;

    // 22.10.6.4, access
    constexpr operator T& () const noexcept;
    constexpr T& get() const noexcept;

    // 22.10.6.5, invocation
    template<class... ArgTypes>
      constexpr invoke_result_t<T&, ArgTypes...> operator()(ArgTypes&&...) const
        noexcept(is_nothrow_invocable_v<T&, ArgTypes...>);

    // 22.10.6.6, comparisons
    friend constexpr bool operator==(reference_wrapper, reference_wrapper);
    friend constexpr bool operator==(reference_wrapper, const T&);
    friend constexpr bool operator==(reference_wrapper, reference_wrapper<const T>);

    friend constexpr auto operator<=>(reference_wrapper, reference_wrapper);
    friend constexpr auto operator<=>(reference_wrapper, const T&);
    friend constexpr auto operator<=>(reference_wrapper, reference_wrapper<const T>);
  };

  template<class T>
    reference_wrapper(T&) -> reference_wrapper<T>;
}
```

1 `reference_wrapper<T>` is a *Cpp17CopyConstructible* and *Cpp17CopyAssignable* wrapper around a reference to an object or function of type `T`.

2 `reference_wrapper<T>` is a trivially copyable type (6.9.1).

3 The template parameter `T` of `reference_wrapper` may be an incomplete type.

[*Note 1*: Using the comparison operators described in 22.10.6.6 with `T` being an incomplete type can lead to an ill-formed program with no diagnostic required (13.8.4.1, 13.5.2.3). — *end note*]

22.10.6.2 Constructors [refwrap.const]

```
template<class U>
  constexpr reference_wrapper(U&& u) noexcept(see below);
```

1 Let *FUN* denote the exposition-only functions

```
void FUN(T&) noexcept;
void FUN(T&&) = delete;
```

2 *Constraints*: The expression `FUN(declval<U>())` is well-formed and `is_same_v<remove_cvref_t<U>, reference_wrapper>` is `false`.

3 *Effects*: Creates a variable `r` as if by `T& r = std::forward<U>(u)`, then constructs a `reference_wrapper` object that stores a reference to `r`.

4 *Remarks*: The exception specification is equivalent to `noexcept(FUN(declval<U>()))`.

```
constexpr reference_wrapper(const reference_wrapper& x) noexcept;
```

5 *Effects*: Constructs a `reference_wrapper` object that stores a reference to `x.get()`.

22.10.6.3 Assignment [refwrap.assign]

```
constexpr reference_wrapper& operator=(const reference_wrapper& x) noexcept;
```

1 *Postconditions*: `*this` stores a reference to `x.get()`.

22.10.6.4 Access [refwrap.access]

```
constexpr operator T& () const noexcept;
```

1 *Returns*: The stored reference.

```
constexpr T& get() const noexcept;
```

2 *Returns*: The stored reference.

22.10.6.5 Invocation [refwrap.invoke]

```
template<class... ArgTypes>
  constexpr invoke_result_t<T&, ArgTypes...>
    operator()(ArgTypes&&... args) const noexcept(is_nothrow_invocable_v<T&, ArgTypes...>);
```

1 *Mandates*: `T` is a complete type.

2 *Returns*: *INVOKE*`(get(), std::forward<ArgTypes>(args)...)` (22.10.4).

22.10.6.6 Comparisons [refwrap.comparisons]

```
friend constexpr bool operator==(reference_wrapper x, reference_wrapper y);
```

1 *Constraints*: The expression `x.get() == y.get()` is well-formed and its result is convertible to `bool`.

2 *Returns*: `x.get() == y.get()`.

```
friend constexpr bool operator==(reference_wrapper x, const T& y);
```

3 *Constraints*: The expression `x.get() == y` is well-formed and its result is convertible to `bool`.

4 *Returns*: `x.get() == y`.

```
friend constexpr bool operator==(reference_wrapper x, reference_wrapper<const T> y);
```

5 *Constraints*: `is_const_v<T>` is `false` and the expression `x.get() == y.get()` is well-formed and its result is convertible to `bool`.

6 *Returns*: `x.get() == y.get()`.

```
friend constexpr auto operator<=>(reference_wrapper x, reference_wrapper y);
```

7 *Constraints*: The expression *synth-three-way*`(x.get(), y.get())` is well-formed.

8 *Returns*: *synth-three-way*`(x.get(), y.get())`.

```
friend constexpr auto operator<=>(reference_wrapper x, const T& y);
```

9 *Constraints*: The expression *synth-three-way*`(x.get(), y)` is well-formed.

10 *Returns*: *synth-three-way*`(x.get(), y)`.

```
friend constexpr auto operator<=>(reference_wrapper x, reference_wrapper<const T> y);
```

11 *Constraints*: `is_const_v<T>` is `false`. The expression *synth-three-way*`(x.get(), y.get())` is well-formed.

12 *Returns*: *synth-three-way*`(x.get(), y.get())`.

22.10.6.7 Helper functions [refwrap.helpers]

1 The template parameter `T` of the following `ref` and `cref` function templates may be an incomplete type.

```
template<class T> constexpr reference_wrapper<T> ref(T& t) noexcept;
```

2 *Returns*: `reference_wrapper<T>(t)`.

```
template<class T> constexpr reference_wrapper<T> ref(reference_wrapper<T> t) noexcept;
```

3 *Returns*: `t`.

```
template<class T> constexpr reference_wrapper<const T> cref(const T& t) noexcept;
```

4 *Returns*: `reference_wrapper<const T>(t)`.

```
template<class T> constexpr reference_wrapper<const T> cref(reference_wrapper<T> t) noexcept;
```

5 *Returns*: `t`.

22.10.6.8 `common_reference` related specializations [refwrap.common.ref]

```
namespace std {
  template<class T>
    constexpr bool is-ref-wrapper = false;                                  // exposition only

  template<class T>
    constexpr bool is-ref-wrapper<reference_wrapper<T>> = true;

  template<class R, class T, class RQ, class TQ>
    concept ref-wrap-common-reference-exists-with =                         // exposition only
      is-ref-wrapper<R> &&
      requires { typename common_reference_t<typename R::type&, TQ>; } &&
      convertible_to<RQ, common_reference_t<typename R::type&, TQ>>;

  template<class R, class T, template<class> class RQual, template<class> class TQual>
    requires (ref-wrap-common-reference-exists-with<R, T, RQual<R>, TQual<T>> &&
              !ref-wrap-common-reference-exists-with<T, R, TQual<T>, RQual<R>>)
  struct basic_common_reference<R, T, RQual, TQual> {
    using type = common_reference_t<typename R::type&, TQual<T>>;
  };

  template<class T, class R, template<class> class TQual, template<class> class RQual>
    requires (ref-wrap-common-reference-exists-with<R, T, RQual<R>, TQual<T>> &&
              !ref-wrap-common-reference-exists-with<T, R, TQual<T>, RQual<R>>)
  struct basic_common_reference<T, R, TQual, RQual> {
    using type = common_reference_t<typename R::type&, TQual<T>>;
  };
}
```

22.10.7 Arithmetic operations [arithmetic.operations]

22.10.7.1 General [arithmetic.operations.general]

1 The library provides basic function object classes for all of the arithmetic operators in the language (7.6.5, 7.6.6).

22.10.7.2 Class template `plus` [arithmetic.operations.plus]

```
template<class T = void> struct plus {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;
```

1 *Returns*: `x + y`.

```
template<> struct plus<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) + std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) + std::forward<U>(u));
```

2 *Returns*: `std::forward<T>(t) + std::forward<U>(u)`.

22.10.7.3 Class template `minus` [arithmetic.operations.minus]

```
template<class T = void> struct minus {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;
```

1 *Returns*: `x - y`.

```
template<> struct minus<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) - std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) - std::forward<U>(u));
```

2 *Returns*: `std::forward<T>(t) - std::forward<U>(u)`.

22.10.7.4 Class template `multiplies` [arithmetic.operations.multiplies]

```
template<class T = void> struct multiplies {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;
```

1 *Returns*: `x * y`.

```
template<> struct multiplies<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) * std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) * std::forward<U>(u));
```

2 *Returns*: `std::forward<T>(t) * std::forward<U>(u)`.

22.10.7.5 Class template `divides` [arithmetic.operations.divides]

```
template<class T = void> struct divides {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;
```

1 *Returns*: `x / y`.

```
template<> struct divides<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) / std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) / std::forward<U>(u));
```

2 *Returns*: `std::forward<T>(t) / std::forward<U>(u)`.

22.10.7.6 Class template `modulus` [arithmetic.operations.modulus]

```
template<class T = void> struct modulus {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;
```

1 *Returns*: `x % y`.

```
template<> struct modulus<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) % std::forward<U>(u));
```

```
  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) % std::forward<U>(u));
```

2 *Returns*: `std::forward<T>(t) % std::forward<U>(u)`.

22.10.7.7 Class template `negate` [arithmetic.operations.negate]

```
template<class T = void> struct negate {
  constexpr T operator()(const T& x) const;
};

constexpr T operator()(const T& x) const;
```

1 *Returns*: `-x`.

```
template<> struct negate<void> {
  template<class T> constexpr auto operator()(T&& t) const
    -> decltype(-std::forward<T>(t));

  using is_transparent = unspecified;
};

template<class T> constexpr auto operator()(T&& t) const
  -> decltype(-std::forward<T>(t));
```

2 *Returns*: `-std::forward<T>(t)`.

22.10.8 Comparisons [comparisons]

22.10.8.1 General [comparisons.general]

1 The library provides basic function object classes for all of the comparison operators in the language (7.6.9, 7.6.10).

2 For templates `less`, `greater`, `less_equal`, and `greater_equal`, the specializations for any pointer type yield a result consistent with the implementation-defined strict total order over pointers (3.28).

[*Note 1*: If `a < b` is well-defined for pointers `a` and `b` of type `P`, then `(a < b) == less<P>()(a, b)`, `(a > b) == greater<P>()(a, b)`, and so forth. — *end note*]

For template specializations `less<void>`, `greater<void>`, `less_equal<void>`, and `greater_equal<void>`, if the call operator calls a built-in operator comparing pointers, the call operator yields a result consistent with the implementation-defined strict total order over pointers.

22.10.8.2 Class template `equal_to` [comparisons.equal.to]

```
template<class T = void> struct equal_to {
  constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
```

1 *Returns*: `x == y`.

```
template<> struct equal_to<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) == std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) == std::forward<U>(u));
```

2 *Returns*: `std::forward<T>(t) == std::forward<U>(u)`.

22.10.8.3 Class template `not_equal_to` [comparisons.not.equal.to]

```
template<class T = void> struct not_equal_to {
  constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
```

1 *Returns*: `x != y`.

```
template<> struct not_equal_to<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) != std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) != std::forward<U>(u));
```

2 *Returns*: `std::forward<T>(t) != std::forward<U>(u)`.

22.10.8.4 Class template `greater` [comparisons.greater]

```
template<class T = void> struct greater {
  constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
```

1 *Returns*: `x > y`.

```
template<> struct greater<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) > std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) > std::forward<U>(u));
```

2 *Returns*: `std::forward<T>(t) > std::forward<U>(u)`.

22.10.8.5 Class template `less` [comparisons.less]

```
template<class T = void> struct less {
  constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
```

1 *Returns*: `x < y`.

```
template<> struct less<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) < std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) < std::forward<U>(u));
```

2 *Returns*: `std::forward<T>(t) < std::forward<U>(u)`.

22.10.8.6 Class template greater_equal [comparisons.greater.equal]

```
template<class T = void> struct greater_equal {
  constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
```

1 *Returns*: x >= y.

```
template<> struct greater_equal<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) >= std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) >= std::forward<U>(u));
```

2 *Returns*: std::forward<T>(t) >= std::forward<U>(u).

22.10.8.7 Class template less_equal [comparisons.less.equal]

```
template<class T = void> struct less_equal {
  constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
```

1 *Returns*: x <= y.

```
template<> struct less_equal<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) <= std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) <= std::forward<U>(u));
```

2 *Returns*: std::forward<T>(t) <= std::forward<U>(u).

22.10.8.8 Class compare_three_way [comparisons.three.way]

```
namespace std {
  struct compare_three_way {
    template<class T, class U>
      constexpr auto operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;
  };
}

template<class T, class U>
  constexpr auto operator()(T&& t, U&& u) const;
```

1 *Constraints*: T and U satisfy three_way_comparable_with.

2 *Preconditions*: If the expression std::forward<T>(t) <=> std::forward<U>(u) results in a call to a built-in operator <=> comparing pointers of type P, the conversion sequences from both T and U to P are equality-preserving (18.2); otherwise, T and U model three_way_comparable_with.

3 *Effects*:

(3.1) — If the expression std::forward<T>(t) <=> std::forward<U>(u) results in a call to a built-in operator <=> comparing pointers of type P, returns strong_ordering::less if (the converted value of) t precedes u in the implementation-defined strict total order over pointers (3.28), strong_ordering::greater if u precedes t, and otherwise strong_ordering::equal.

(3.2) — Otherwise, equivalent to: `return std::forward<T>(t) <=> std::forward<U>(u);`

22.10.9 Concept-constrained comparisons [range.cmp]

```
struct ranges::equal_to {
  template<class T, class U>
    constexpr bool operator()(T&& t, U&& u) const;

  using is_transparent = unspecified;
};
```

```
template<class T, class U>
  constexpr bool operator()(T&& t, U&& u) const;
```

1 *Constraints*: `T` and `U` satisfy `equality_comparable_with`.

2 *Preconditions*: If the expression `std::forward<T>(t) == std::forward<U>(u)` results in a call to a built-in operator `==` comparing pointers of type `P`, the conversion sequences from both `T` and `U` to `P` are equality-preserving (18.2); otherwise, `T` and `U` model `equality_comparable_with`.

3 *Effects*:

(3.1) — If the expression `std::forward<T>(t) == std::forward<U>(u)` results in a call to a built-in operator `==` comparing pointers: returns `false` if either (the converted value of) `t` precedes `u` or `u` precedes `t` in the implementation-defined strict total order over pointers (3.28) and otherwise `true`.

(3.2) — Otherwise, equivalent to: `return std::forward<T>(t) == std::forward<U>(u);`

```
struct ranges::not_equal_to {
  template<class T, class U>
    constexpr bool operator()(T&& t, U&& u) const;

  using is_transparent = unspecified;
};
```

```
template<class T, class U>
  constexpr bool operator()(T&& t, U&& u) const;
```

4 *Constraints*: `T` and `U` satisfy `equality_comparable_with`.

5 *Effects*: Equivalent to:

```
return !ranges::equal_to{}(std::forward<T>(t), std::forward<U>(u));
```

```
struct ranges::greater {
  template<class T, class U>
    constexpr bool operator()(T&& t, U&& u) const;

  using is_transparent = unspecified;
};
```

```
template<class T, class U>
  constexpr bool operator()(T&& t, U&& u) const;
```

6 *Constraints*: `T` and `U` satisfy `totally_ordered_with`.

7 *Effects*: Equivalent to:

```
return ranges::less{}(std::forward<U>(u), std::forward<T>(t));
```

```
struct ranges::less {
  template<class T, class U>
    constexpr bool operator()(T&& t, U&& u) const;

  using is_transparent = unspecified;
};
```

```
template<class T, class U>
  constexpr bool operator()(T&& t, U&& u) const;
```

8 *Constraints*: `T` and `U` satisfy `totally_ordered_with`.

9 *Preconditions*: If the expression `std::forward<T>(t) < std::forward<U>(u)` results in a call to a built-in operator `<` comparing pointers of type `P`, the conversion sequences from both `T` and `U` to `P` are equality-preserving (18.2); otherwise, `T` and `U` model `totally_ordered_with`. For any expressions `ET` and `EU` such that `decltype((ET))` is `T` and `decltype((EU))` is `U`, exactly one of `ranges::less{}(ET, EU)`, `ranges::less{}(EU, ET)`, or `ranges::equal_to{}(ET, EU)` is `true`.

10 *Effects*:

(10.1) — If the expression `std::forward<T>(t) < std::forward<U>(u)` results in a call to a built-in operator `<` comparing pointers: returns `true` if (the converted value of) `t` precedes `u` in the implementation-defined strict total order over pointers (3.28) and otherwise `false`.

(10.2) — Otherwise, equivalent to: `return std::forward<T>(t) < std::forward<U>(u);`

```
struct ranges::greater_equal {
  template<class T, class U>
    constexpr bool operator()(T&& t, U&& u) const;

  using is_transparent = unspecified;
};

template<class T, class U>
  constexpr bool operator()(T&& t, U&& u) const;
```

11 *Constraints*: `T` and `U` satisfy `totally_ordered_with`.

12 *Effects*: Equivalent to:

```
return !ranges::less{}(std::forward<T>(t), std::forward<U>(u));
```

```
struct ranges::less_equal {
  template<class T, class U>
    constexpr bool operator()(T&& t, U&& u) const;

  using is_transparent = unspecified;
};

template<class T, class U>
  constexpr bool operator()(T&& t, U&& u) const;
```

13 *Constraints*: `T` and `U` satisfy `totally_ordered_with`.

14 *Effects*: Equivalent to:

```
return !ranges::less{}(std::forward<U>(u), std::forward<T>(t));
```

22.10.10 Logical operations [logical.operations]

22.10.10.1 General [logical.operations.general]

1 The library provides basic function object classes for all of the logical operators in the language (7.6.14, 7.6.15, 7.6.2.2).

22.10.10.2 Class template `logical_and` [logical.operations.and]

```
template<class T = void> struct logical_and {
  constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
```

1 *Returns*: `x && y`.

```
template<> struct logical_and<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) && std::forward<U>(u));

  using is_transparent = unspecified;
};
```

```
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) && std::forward<U>(u));
```

2 *Returns*: `std::forward<T>(t) && std::forward<U>(u)`.

22.10.10.3 Class template `logical_or` [logical.operations.or]

```
template<class T = void> struct logical_or {
  constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
```

1 *Returns*: `x || y`.

```
template<> struct logical_or<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) || std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) || std::forward<U>(u));
```

2 *Returns*: `std::forward<T>(t) || std::forward<U>(u)`.

22.10.10.4 Class template `logical_not` [logical.operations.not]

```
template<class T = void> struct logical_not {
  constexpr bool operator()(const T& x) const;
};

constexpr bool operator()(const T& x) const;
```

1 *Returns*: `!x`.

```
template<> struct logical_not<void> {
  template<class T> constexpr auto operator()(T&& t) const
    -> decltype(!std::forward<T>(t));

  using is_transparent = unspecified;
};

template<class T> constexpr auto operator()(T&& t) const
  -> decltype(!std::forward<T>(t));
```

2 *Returns*: `!std::forward<T>(t)`.

22.10.11 Bitwise operations [bitwise.operations]

22.10.11.1 General [bitwise.operations.general]

1 The library provides basic function object classes for all of the bitwise operators in the language (7.6.11, 7.6.13, 7.6.12, 7.6.2.2).

22.10.11.2 Class template `bit_and` [bitwise.operations.and]

```
template<class T = void> struct bit_and {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;
```

1 *Returns*: `x & y`.

```
template<> struct bit_and<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) & std::forward<U>(u));
```

```
  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) & std::forward<U>(u));
```

2 *Returns*: `std::forward<T>(t) & std::forward<U>(u)`.

22.10.11.3 Class template `bit_or` [bitwise.operations.or]

```
template<class T = void> struct bit_or {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;
```

1 *Returns*: `x | y`.

```
template<> struct bit_or<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) | std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) | std::forward<U>(u));
```

2 *Returns*: `std::forward<T>(t) | std::forward<U>(u)`.

22.10.11.4 Class template `bit_xor` [bitwise.operations.xor]

```
template<class T = void> struct bit_xor {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;
```

1 *Returns*: `x ^ y`.

```
template<> struct bit_xor<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) ^ std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) ^ std::forward<U>(u));
```

2 *Returns*: `std::forward<T>(t) ^ std::forward<U>(u)`.

22.10.11.5 Class template `bit_not` [bitwise.operations.not]

```
template<class T = void> struct bit_not {
  constexpr T operator()(const T& x) const;
};

constexpr T operator()(const T& x) const;
```

1 *Returns*: `~x`.

```
template<> struct bit_not<void> {
  template<class T> constexpr auto operator()(T&& t) const
    -> decltype(~std::forward<T>(t));

  using is_transparent = unspecified;
};
```

```
template<class T> constexpr auto operator()(T&& t) const
  -> decltype(~std::forward<T>(t));
```

2 *Returns*: `~std::forward<T>(t)`.

22.10.12 Class `identity` [func.identity]

```
struct identity {
  template<class T>
    constexpr T&& operator()(T&& t) const noexcept;

  using is_transparent = unspecified;
};

template<class T>
  constexpr T&& operator()(T&& t) const noexcept;
```

1 *Effects*: Equivalent to: `return std::forward<T>(t);`

22.10.13 Function template `not_fn` [func.not.fn]

```
template<class F> constexpr unspecified not_fn(F&& f);
```

1 In the text that follows:

(1.1) — `g` is a value of the result of a `not_fn` invocation,

(1.2) — `FD` is the type `decay_t<F>`,

(1.3) — `fd` is the target object of `g` (22.10.3) of type `FD`, direct-non-list-initialized with `std::forward<F>(f)`,

(1.4) — `call_args` is an argument pack used in a function call expression (7.6.1.3) of `g`.

2 *Mandates*: `is_constructible_v<FD, F> && is_move_constructible_v<FD>` is `true`.

3 *Preconditions*: `FD` meets the *Cpp17MoveConstructible* requirements.

4 *Returns*: A perfect forwarding call wrapper (22.10.4) `g` with call pattern `!invoke(fd, call_args...)`.

5 *Throws*: Any exception thrown by the initialization of `fd`.

```
template<auto f> constexpr unspecified not_fn() noexcept;
```

6 In the text that follows:

(6.1) — `F` is the type of `f`,

(6.2) — `g` is a value of the result of a `not_fn` invocation,

(6.3) — `call_args` is an argument pack used in a function call expression (7.6.1.3) of `g`.

7 *Mandates*: If `is_pointer_v<F> || is_member_pointer_v<F>` is `true`, then `f != nullptr` is `true`.

8 *Returns*: A perfect forwarding call wrapper (22.10.4) `g` whose target object is a copy of `cw<f>`, and whose call pattern is `!invoke(f, call_args...)`.

22.10.14 Function templates `bind_front` and `bind_back` [func.bind.partial]

```
template<class F, class... Args>
  constexpr unspecified bind_front(F&& f, Args&&... args);
template<class F, class... Args>
  constexpr unspecified bind_back(F&& f, Args&&... args);
```

1 Within this subclause:

(1.1) — `g` is a value of the result of a `bind_front` or `bind_back` invocation,

(1.2) — `FD` is the type `decay_t<F>`,

(1.3) — `fd` is the target object of `g` (22.10.3) of type `FD`, direct-non-list-initialized with `std::forward<F>(f)`,

(1.4) — `BoundArgs` is a pack that denotes `decay_t<Args>...`,

(1.5) — `bound_args` is a pack of bound argument entities of `g` (22.10.3) of types `BoundArgs...`, direct-non-list-initialized with `std::forward<Args>(args)...`, respectively, and

(1.6) — `call_args` is an argument pack used in a function call expression (7.6.1.3) of `g`.

2 *Mandates*:

```
is_constructible_v<FD, F> &&
is_move_constructible_v<FD> &&
(is_constructible_v<BoundArgs, Args> && ...) &&
(is_move_constructible_v<BoundArgs> && ...)
```

is `true`.

3 *Preconditions*: `FD` meets the *Cpp17MoveConstructible* requirements. For each $\texttt{T}_i$ in `BoundArgs`, if $\texttt{T}_i$ is an object type, $\texttt{T}_i$ meets the *Cpp17MoveConstructible* requirements.

4 *Returns*: A perfect forwarding call wrapper (22.10.4) `g` with call pattern:

(4.1) — `invoke(fd, bound_args..., call_args...)` for a `bind_front` invocation, or

(4.2) — `invoke(fd, call_args..., bound_args...)` for a `bind_back` invocation.

5 *Throws*: Any exception thrown by the initialization of the state entities of `g` (22.10.3).

```
template<auto f, class... Args>
  constexpr unspecified bind_front(Args&&... args);
template<auto f, class... Args>
  constexpr unspecified bind_back(Args&&... args);
```

6 Within this subclause:

(6.1) — `F` is the type of `f`,

(6.2) — `g` is a value of the result of a `bind_front` or `bind_back` invocation,

(6.3) — `BoundArgs` is a pack that denotes `decay_t<Args>...`,

(6.4) — `bound_args` is a pack of bound argument entities of `g` (22.10.3) of types `BoundArgs...`, direct-non-list-initialized with `std::forward<Args>(args)...`, respectively, and

(6.5) — `call_args` is an argument pack used in a function call expression (7.6.1.3) of `g`.

7 *Mandates*:

(7.1) — `(is_constructible_v<BoundArgs, Args> && ...)` is `true`, and

(7.2) — `(is_move_constructible_v<BoundArgs> && ...)` is `true`, and

(7.3) — if `is_pointer_v<F> || is_member_pointer_v<F>` is `true`, then `f != nullptr` is `true`.

8 *Preconditions*: For each $\texttt{T}_i$ in `BoundArgs`, $\texttt{T}_i$ meets the *Cpp17MoveConstructible* requirements.

9 *Returns*: A perfect forwarding call wrapper (22.10.4) `g` whose target object is a copy of `cw<f>`, and whose call pattern is:

(9.1) — `invoke(f, bound_args..., call_args...)` for a `bind_front` invocation, or

(9.2) — `invoke(f, call_args..., bound_args...)` for a `bind_back` invocation.

10 *Throws*: Any exception thrown by the initialization of `bound_args`.

22.10.15 Function object binders [func.bind]

22.10.15.1 General [func.bind.general]

1 Subclause 22.10.15 describes a uniform mechanism for binding arguments of callable objects.

22.10.15.2 Class template `is_bind_expression` [func.bind.isbind]

```
namespace std {
  template<class T> struct is_bind_expression;  // see below
}
```

1 The class template `is_bind_expression` can be used to detect function objects generated by `bind`. The function template `bind` uses `is_bind_expression` to detect subexpressions.

2 Specializations of the `is_bind_expression` template shall meet the *Cpp17UnaryTypeTrait* requirements (21.3.2). The implementation provides a definition that has a base characteristic of `true_type` if `T` is a type returned from `bind`, otherwise it has a base characteristic of `false_type`. A program may specialize this template for a program-defined type `T` to have a base characteristic of `true_type` to indicate that `T` should be treated as a subexpression in a `bind` call.

22.10.15.3 Class template `is_placeholder` [func.bind.isplace]

```
namespace std {
  template<class T> struct is_placeholder;      // see below
}
```

1 The class template `is_placeholder` can be used to detect the standard placeholders `_1`, `_2`, and so on (22.10.15.5). The function template `bind` uses `is_placeholder` to detect placeholders.

2 Specializations of the `is_placeholder` template shall meet the *Cpp17UnaryTypeTrait* requirements (21.3.2). The implementation provides a definition that has the base characteristic of `integral_constant<int, J>` if `T` is the type of `std::placeholders::_J`, otherwise it has a base characteristic of `integral_constant<int, 0>`. A program may specialize this template for a program-defined type `T` to have a base characteristic of `integral_constant<int, N>` with `N > 0` to indicate that `T` should be treated as a placeholder type.

22.10.15.4 Function template `bind` [func.bind.bind]

1 In the text that follows:

(1.1) — `g` is a value of the result of a `bind` invocation,

(1.2) — `FD` is the type `decay_t<F>`,

(1.3) — `fd` is an lvalue that is a target object of `g` (22.10.3) of type `FD` direct-non-list-initialized with `std::forward<F>(f)`,

(1.4) — $\texttt{T}_i$ is the i^{th} type in the template parameter pack `BoundArgs`,

(1.5) — $\texttt{TD}_i$ is the type `decay_t<`$\texttt{T}_i$`>`,

(1.6) — $\texttt{t}_i$ is the i^{th} argument in the function parameter pack `bound_args`,

(1.7) — $\texttt{td}_i$ is a bound argument entity of `g` (22.10.3) of type $\texttt{TD}_i$ direct-non-list-initialized with `std::forward<`$\texttt{T}_i$`>(`$\texttt{t}_i$`)`,

(1.8) — $\texttt{U}_j$ is the j^{th} deduced type of the `UnBoundArgs&&...` parameter of the argument forwarding call wrapper, and

(1.9) — $\texttt{u}_j$ is the j^{th} argument associated with $\texttt{U}_j$.

```
template<class F, class... BoundArgs>
  constexpr unspecified bind(F&& f, BoundArgs&&... bound_args);
template<class R, class F, class... BoundArgs>
  constexpr unspecified bind(F&& f, BoundArgs&&... bound_args);
```

2 *Mandates*: `is_constructible_v<FD, F>` is `true`. For each $\texttt{T}_i$ in `BoundArgs`, `is_constructible_v<`$\texttt{TD}_i$`, `$\texttt{T}_i$`>` is `true`.

3 *Preconditions*: `FD` and each $\texttt{TD}_i$ meet the *Cpp17MoveConstructible* and *Cpp17Destructible* requirements. *INVOKE*`(fd, `$\texttt{w}_1$`, `$\texttt{w}_2$`, ..., `$\texttt{w}_N$`)` (22.10.4) is a valid expression for some values $\texttt{w}_1$, $\texttt{w}_2$, ..., $\texttt{w}_N$, where N has the value `sizeof...(bound_args)`.

4 *Returns*: An argument forwarding call wrapper `g` (22.10.4). A program that attempts to invoke a volatile-qualified `g` is ill-formed. When `g` is not volatile-qualified, invocation of `g(`$\texttt{u}_1$`, `$\texttt{u}_2$`, ..., `$\texttt{u}_M$`)` is expression-equivalent (3.22) to

```
INVOKE(static_cast<Vfd>(vfd),
       static_cast<V1>(v1), static_cast<V2>(v2), ..., static_cast<VN>(vN))
```

for the first overload, and

```
INVOKE<R>(static_cast<Vfd>(vfd),
          static_cast<V1>(v1), static_cast<V2>(v2), ..., static_cast<VN>(vN))
```

for the second overload, where the values and types of the target argument $\texttt{v}_{\texttt{fd}}$ and of the bound arguments $\texttt{v}_1$, $\texttt{v}_2$, ..., $\texttt{v}_N$ are determined as specified below.

5 *Throws*: Any exception thrown by the initialization of the state entities of `g`.

6 [*Note 1*: If all of `FD` and $\texttt{TD}_i$ meet the requirements of *Cpp17CopyConstructible*, then the return type meets the requirements of *Cpp17CopyConstructible*. — *end note*]

7 The values of the *bound arguments* $\texttt{v}_1$, $\texttt{v}_2$, ..., $\texttt{v}_N$ and their corresponding types $\texttt{V}_1$, $\texttt{V}_2$, ..., $\texttt{V}_N$ depend on the types $\texttt{TD}_i$ derived from the call to `bind` and the cv-qualifiers *cv* of the call wrapper `g` as follows:

(7.1) — if $\texttt{TD}_i$ is `reference_wrapper<T>`, the argument is $\texttt{td}_i$`.get()` and its type $\texttt{V}_i$ is `T&`;

(7.2) — if the value of `is_bind_expression_v<TD_i>` is `true`, the argument is

`static_cast<cv TD_i&>(td_i)(std::forward<U_j>(u_j)...)`

and its type `V_i` is `invoke_result_t<cv TD_i&, U_j...>&&`;

(7.3) — if the value `j` of `is_placeholder_v<TD_i>` is not zero, the argument is `std::forward<U_j>(u_j)` and its type `V_i` is `U_j&&`;

(7.4) — otherwise, the value is `td_i` and its type `V_i` is *cv* `TD_i&`.

8 The value of the target argument `v_fd` is `fd` and its corresponding type `V_fd` is *cv* `FD&`.

22.10.15.5 Placeholders [func.bind.place]

```
namespace std::placeholders {
  // M is the number of placeholders
  see below _1;
  see below _2;
            ⋮
  see below _M;
}
```

1 The number *M* of placeholders is implementation-defined.

2 All placeholder types meet the *Cpp17DefaultConstructible* and *Cpp17CopyConstructible* requirements, and their default constructors and copy/move constructors are constexpr functions that do not throw exceptions. It is implementation-defined whether placeholder types meet the *Cpp17CopyAssignable* requirements, but if so, their copy assignment operators are constexpr functions that do not throw exceptions.

3 Placeholders should be defined as:

```
inline constexpr unspecified _1{};
```

If they are not, they are declared as:

```
extern unspecified _1;
```

4 Placeholders are freestanding items (16.3.3.7).

22.10.16 Function template `mem_fn` [func.memfn]

```
template<class R, class T> constexpr unspecified mem_fn(R T::* pm) noexcept;
```

1 *Returns*: A simple call wrapper (22.10.4) `fn` with call pattern `invoke(pmd, call_args...)`, where `pmd` is the target object of `fn` of type `R T::*` direct-non-list-initialized with `pm`, and `call_args` is an argument pack used in a function call expression (7.6.1.3) of `fn`.

22.10.17 Polymorphic function wrappers [func.wrap]

22.10.17.1 General [func.wrap.general]

1 Subclause 22.10.17 describes polymorphic wrapper classes that encapsulate arbitrary callable objects.

2 Let `t` be an object of a type that is a specialization of `function`, `copyable_function`, `move_only_function`, or `function_ref`, such that the target object `x` of `t` has a type that is a specialization of `function`, `copyable_function`, `move_only_function`, or `function_ref`. Each argument of the invocation of `x` evaluated as part of the invocation of `t` may alias an argument in the same position in the invocation of `t` that has the same type, even if the corresponding parameter is not of reference type.

[*Example 1*:

```
move_only_function<void(T)> f{copyable_function<void(T)>{[](T) {}}};
T t;
f(t);                                   // it is unspecified how many copies of T are made
```

— *end example*]

3 *Recommended practice*: Implementations should avoid double wrapping when constructing polymorphic wrappers from one another.

22.10.17.2 Class `bad_function_call` [func.wrap.badcall]

1 An exception of type `bad_function_call` is thrown by `function::operator()` (22.10.17.3.5) when the function wrapper object has no target.

```
namespace std {
  class bad_function_call : public exception {
  public:
    // see 17.9.3 for the specification of the special member functions
    const char* what() const noexcept override;
  };
}
```

```
const char* what() const noexcept override;
```

2 *Returns*: An implementation-defined NTBS.

22.10.17.3 Class template `function` [func.wrap.func]

22.10.17.3.1 General [func.wrap.func.general]

```
namespace std {
  template<class R, class... ArgTypes>
  class function<R(ArgTypes...)> {
  public:
    using result_type = R;

    // 22.10.17.3.2, construct/copy/destroy
    function() noexcept;
    function(nullptr_t) noexcept;
    function(const function&);
    function(function&&) noexcept;
    template<class F> function(F&&);

    function& operator=(const function&);
    function& operator=(function&&);
    function& operator=(nullptr_t) noexcept;
    template<class F> function& operator=(F&&);
    template<class F> function& operator=(reference_wrapper<F>) noexcept;

    ~function();

    // 22.10.17.3.3, function modifiers
    void swap(function&) noexcept;

    // 22.10.17.3.4, function capacity
    explicit operator bool() const noexcept;

    // 22.10.17.3.5, function invocation
    R operator()(ArgTypes...) const;

    // 22.10.17.3.6, function target access
    const type_info& target_type() const noexcept;
    template<class T>       T* target() noexcept;
    template<class T> const T* target() const noexcept;
  };

  template<class R, class... ArgTypes>
    function(R(*)(ArgTypes...)) -> function<R(ArgTypes...)>;

  template<class F> function(F) -> function<see below>;
}
```

1 The `function` class template provides polymorphic wrappers that generalize the notion of a function pointer. Wrappers can store, copy, and call arbitrary callable objects (22.10.3), given a call signature (22.10.3).

2 The `function` class template is a call wrapper (22.10.3) whose call signature (22.10.3) is `R(ArgTypes...)`.

3 [*Note 1*: The types deduced by the deduction guides for `function` might change in future revisions of C++. — *end note*]

22.10.17.3.2 Constructors and destructor [func.wrap.func.con]

`function() noexcept;`

1 *Postconditions*: `!*this`.

`function(nullptr_t) noexcept;`

2 *Postconditions*: `!*this`.

`function(const function& f);`

3 *Postconditions*: `!*this` if `!f`; otherwise, the target object of `*this` is a copy of the target object of `f`.

4 *Throws*: Nothing if `f`'s target is a specialization of `reference_wrapper` or a function pointer. Otherwise, may throw `bad_alloc` or any exception thrown by the copy constructor of the stored callable object.

5 *Recommended practice*: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where `f`'s target is an object holding only a pointer or reference to an object and a member function pointer.

`function(function&& f) noexcept;`

6 *Postconditions*: If `!f`, `*this` has no target; otherwise, the target of `*this` is equivalent to the target of `f` before the construction, and `f` is in a valid state with an unspecified value.

7 *Recommended practice*: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where `f`'s target is an object holding only a pointer or reference to an object and a member function pointer.

`template<class F> function(F&& f);`

8 Let `FD` be `decay_t<F>`.

9 *Constraints*:

(9.1) — `is_same_v<remove_cvref_t<F>, function>` is `false`, and

(9.2) — `is_invocable_r_v<R, FD&, ArgTypes...>` is `true`.

10 *Mandates*:

(10.1) — `is_copy_constructible_v<FD>` is `true`, and

(10.2) — `is_constructible_v<FD, F>` is `true`.

11 *Preconditions*: `FD` meets the *Cpp17CopyConstructible* requirements.

12 *Postconditions*: `!*this` is `true` if any of the following hold:

(12.1) — `f` is a null function pointer value.

(12.2) — `f` is a null member pointer value.

(12.3) — `remove_cvref_t<F>` is a specialization of the `function` class template, and `!f` is `true`.

13 Otherwise, `*this` has a target object of type `FD` direct-non-list-initialized with `std::forward<F>(f)`.

14 *Throws*: Nothing if `FD` is a specialization of `reference_wrapper` or a function pointer type. Otherwise, may throw `bad_alloc` or any exception thrown by the initialization of the target object.

15 *Recommended practice*: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where `f` refers to an object holding only a pointer or reference to an object and a member function pointer.

`template<class F> function(F) -> function<`*see below*`>;`

16 *Constraints*: `&F::operator()` is well-formed when treated as an unevaluated operand and either

(16.1) — `F::operator()` is a non-static member function and `decltype(&F::operator())` is either of the form `R(G::*)(A...)` *cv* `&`$_{opt}$ `noexcept`$_{opt}$ or of the form `R(*)(G, A...) noexcept`$_{opt}$ for a type `G`, or

(16.2) — `F::operator()` is a static member function and `decltype(&F::operator())` is of the form `R(*)(A...) noexcept`$_{opt}$.

17 *Remarks*: The deduced type is `function<R(A...)>`.

18 [*Example 1*:

```
void f() {
  int i{5};
  function g = [&](double) { return i; };        // deduces function<int(double)>
}
```

— *end example*]

```
function& operator=(const function& f);
```

19 *Effects*: As if by `function(f).swap(*this);`

20 *Returns*: `*this`.

```
function& operator=(function&& f);
```

21 *Effects*: Replaces the target of `*this` with the target of `f`.

22 *Returns*: `*this`.

```
function& operator=(nullptr_t) noexcept;
```

23 *Effects*: If `*this != nullptr`, destroys the target of `this`.

24 *Postconditions*: `!(*this)`.

25 *Returns*: `*this`.

```
template<class F> function& operator=(F&& f);
```

26 *Constraints*: `is_invocable_r_v<R, decay_t<F>&, ArgTypes...>` is `true`.

27 *Effects*: As if by: `function(std::forward<F>(f)).swap(*this);`

28 *Returns*: `*this`.

```
template<class F> function& operator=(reference_wrapper<F> f) noexcept;
```

29 *Effects*: As if by: `function(f).swap(*this);`

30 *Returns*: `*this`.

```
~function();
```

31 *Effects*: If `*this != nullptr`, destroys the target of `this`.

22.10.17.3.3 Modifiers [func.wrap.func.mod]

```
void swap(function& other) noexcept;
```

1 *Effects*: Interchanges the target objects of `*this` and `other`.

22.10.17.3.4 Capacity [func.wrap.func.cap]

```
explicit operator bool() const noexcept;
```

1 *Returns*: `true` if `*this` has a target, otherwise `false`.

22.10.17.3.5 Invocation [func.wrap.func.inv]

```
R operator()(ArgTypes... args) const;
```

1 *Returns*: *INVOKE*`<R>(f, std::forward<ArgTypes>(args)...)` (22.10.4), where `f` is the target object (22.10.3) of `*this`.

2 *Throws*: `bad_function_call` if `!*this`; otherwise, any exception thrown by the target object.

22.10.17.3.6 Target access [func.wrap.func.targ]

```
const type_info& target_type() const noexcept;
```

1 *Returns*: If `*this` has a target of type `T`, `typeid(T)`; otherwise, `typeid(void)`.

```
template<class T>       T* target() noexcept;
template<class T> const T* target() const noexcept;
```

2 *Returns*: If `target_type() == typeid(T)` a pointer to the stored function target; otherwise a null pointer.

22.10.17.3.7 Null pointer comparison operator functions [func.wrap.func.nullptr]

```
template<class R, class... ArgTypes>
  bool operator==(const function<R(ArgTypes...)>& f, nullptr_t) noexcept;
```

1 *Returns*: `!f`.

22.10.17.3.8 Specialized algorithms [func.wrap.func.alg]

```
template<class R, class... ArgTypes>
  void swap(function<R(ArgTypes...)>& f1, function<R(ArgTypes...)>& f2) noexcept;
```

1 *Effects*: As if by: `f1.swap(f2);`

22.10.17.4 Move-only wrapper [func.wrap.move]

22.10.17.4.1 General [func.wrap.move.general]

1 The header provides partial specializations of `move_only_function` for each combination of the possible replacements of the placeholders *cv*, *ref*, and *noex* where

(1.1) — *cv* is either const or empty,

(1.2) — *ref* is either `&`, `&&`, or empty, and

(1.3) — *noex* is either `true` or `false`.

2 For each of the possible combinations of the placeholders mentioned above, there is a placeholder *inv-quals* defined as follows:

(2.1) — If *ref* is empty, let *inv-quals* be *cv*`&`,

(2.2) — otherwise, let *inv-quals* be *cv ref*.

22.10.17.4.2 Class template `move_only_function` [func.wrap.move.class]

```
namespace std {
  template<class R, class... ArgTypes>
  class move_only_function<R(ArgTypes...) cv ref noexcept(noex)> {
  public:
    using result_type = R;

    // 22.10.17.4.3, constructors, assignments, and destructor
    move_only_function() noexcept;
    move_only_function(nullptr_t) noexcept;
    move_only_function(move_only_function&&) noexcept;
    template<class F> move_only_function(F&&);
    template<class T, class... Args>
      explicit move_only_function(in_place_type_t<T>, Args&&...);
    template<class T, class U, class... Args>
      explicit move_only_function(in_place_type_t<T>, initializer_list<U>, Args&&...);

    move_only_function& operator=(move_only_function&&);
    move_only_function& operator=(nullptr_t) noexcept;
    template<class F> move_only_function& operator=(F&&);

    ~move_only_function();

    // 22.10.17.4.4, invocation
    explicit operator bool() const noexcept;
    R operator()(ArgTypes...) cv ref noexcept(noex);

    // 22.10.17.4.5, utility
    void swap(move_only_function&) noexcept;
    friend void swap(move_only_function&, move_only_function&) noexcept;
    friend bool operator==(const move_only_function&, nullptr_t) noexcept;
```

```
  private:
    template<class VT>
      static constexpr bool is-callable-from = see below;        // exposition only
  };
}
```

1 The `move_only_function` class template provides polymorphic wrappers that generalize the notion of a callable object (22.10.3). These wrappers can store, move, and call arbitrary callable objects, given a call signature.

2 *Recommended practice*: Implementations should avoid the use of dynamically allocated memory for a small contained value.

[*Note 1*: Such small-object optimization can only be applied to a type `T` for which `is_nothrow_move_constructible_v<T>` is `true`. — *end note*]

22.10.17.4.3 Constructors, assignments, and destructor [func.wrap.move.ctor]

```
template<class VT>
  static constexpr bool is-callable-from = see below;
```

1 If *noex* is `true`, *is-callable-from*`<VT>` is equal to:

```
is_nothrow_invocable_r_v<R, VT cv ref, ArgTypes...> &&
is_nothrow_invocable_r_v<R, VT inv-quals, ArgTypes...>
```

Otherwise, *is-callable-from*`<VT>` is equal to:

```
is_invocable_r_v<R, VT cv ref, ArgTypes...> &&
is_invocable_r_v<R, VT inv-quals, ArgTypes...>
```

```
move_only_function() noexcept;
move_only_function(nullptr_t) noexcept;
```

2 *Postconditions*: `*this` has no target object.

```
move_only_function(move_only_function&& f) noexcept;
```

3 *Postconditions*: The target object of `*this` is the target object `f` had before construction, and `f` is in a valid state with an unspecified value.

```
template<class F> move_only_function(F&& f);
```

4 Let `VT` be `decay_t<F>`.

5 *Constraints*:

(5.1) — `remove_cvref_t<F>` is not the same type as `move_only_function`, and

(5.2) — `remove_cvref_t<F>` is not a specialization of `in_place_type_t`, and

(5.3) — *is-callable-from*`<VT>` is `true`.

6 *Mandates*: `is_constructible_v<VT, F>` is `true`.

7 *Preconditions*: `VT` meets the *Cpp17Destructible* requirements, and if `is_move_constructible_v<VT>` is `true`, `VT` meets the *Cpp17MoveConstructible* requirements.

8 *Postconditions*: `*this` has no target object if any of the following hold:

(8.1) — `f` is a null function pointer value,

(8.2) — `f` is a null member pointer value, or

(8.3) — `remove_cvref_t<F>` is a specialization of the `move_only_function` or `copyable_function` class template, and `f` has no target object.

Otherwise, `*this` has a target object of type `VT` direct-non-list-initialized with `std::forward<F>(f)`.

9 *Throws*: Any exception thrown by the initialization of the target object. May throw `bad_alloc` unless `VT` is a function pointer or a specialization of `reference_wrapper`.

```
template<class T, class... Args>
  explicit move_only_function(in_place_type_t<T>, Args&&... args);
```

10 Let `VT` be `decay_t<T>`.

11 *Constraints*:

(11.1) — `is_constructible_v<VT, Args...>` is `true`, and

(11.2) — *`is-callable-from`*`<VT>` is `true`.

12 *Mandates*: `VT` is the same type as `T`.

13 *Preconditions*: `VT` meets the *Cpp17Destructible* requirements, and if `is_move_constructible_v<VT>` is `true`, `VT` meets the *Cpp17MoveConstructible* requirements.

14 *Postconditions*: `*this` has a target object of type `VT` direct-non-list-initialized with `std::forward<Args>(args)...`.

15 *Throws*: Any exception thrown by the initialization of the target object. May throw `bad_alloc` unless `VT` is a function pointer or a specialization of `reference_wrapper`.

```
template<class T, class U, class... Args>
  explicit move_only_function(in_place_type_t<T>, initializer_list<U> ilist, Args&&... args);
```

16 Let `VT` be `decay_t<T>`.

17 *Constraints*:

(17.1) — `is_constructible_v<VT, initializer_list<U>&, Args...>` is `true`, and

(17.2) — *`is-callable-from`*`<VT>` is `true`.

18 *Mandates*: `VT` is the same type as `T`.

19 *Preconditions*: `VT` meets the *Cpp17Destructible* requirements, and if `is_move_constructible_v<VT>` is `true`, `VT` meets the *Cpp17MoveConstructible* requirements.

20 *Postconditions*: `*this` has a target object of type `VT` direct-non-list-initialized with `ilist, std::forward<Args>(args)...`.

21 *Throws*: Any exception thrown by the initialization of the target object. May throw `bad_alloc` unless `VT` is a function pointer or a specialization of `reference_wrapper`.

```
move_only_function& operator=(move_only_function&& f);
```

22 *Effects*: Equivalent to: `move_only_function(std::move(f)).swap(*this);`

23 *Returns*: `*this`.

```
move_only_function& operator=(nullptr_t) noexcept;
```

24 *Effects*: Destroys the target object of `*this`, if any.

25 *Returns*: `*this`.

```
template<class F> move_only_function& operator=(F&& f);
```

26 *Effects*: Equivalent to: `move_only_function(std::forward<F>(f)).swap(*this);`

27 *Returns*: `*this`.

```
~move_only_function();
```

28 *Effects*: Destroys the target object of `*this`, if any.

22.10.17.4.4 Invocation [func.wrap.move.inv]

```
explicit operator bool() const noexcept;
```

1 *Returns*: `true` if `*this` has a target object, otherwise `false`.

```
R operator()(ArgTypes... args) cv ref noexcept(noex);
```

2 *Preconditions*: `*this` has a target object.

3 *Effects*: Equivalent to:

```
return INVOKE<R>(static_cast<F inv-quals>(f), std::forward<ArgTypes>(args)...);
```

where `f` is an lvalue designating the target object of `*this` and `F` is the type of `f`.

22.10.17.4.5 Utility [func.wrap.move.util]

```
void swap(move_only_function& other) noexcept;
```

1 *Effects*: Exchanges the target objects of `*this` and `other`.

```
friend void swap(move_only_function& f1, move_only_function& f2) noexcept;
```

2 *Effects*: Equivalent to `f1.swap(f2)`.

```
friend bool operator==(const move_only_function& f, nullptr_t) noexcept;
```

3 *Returns*: `true` if `f` has no target object, otherwise `false`.

22.10.17.5 Copyable wrapper [func.wrap.copy]

22.10.17.5.1 General [func.wrap.copy.general]

1 The header provides partial specializations of `copyable_function` for each combination of the possible replacements of the placeholders *cv*, *ref*, and *noex* where

(1.1) — *cv* is either const or empty,

(1.2) — *ref* is either `&`, `&&`, or empty, and

(1.3) — *noex* is either `true` or `false`.

2 For each of the possible combinations of the placeholders mentioned above, there is a placeholder *inv-quals* defined as follows:

(2.1) — If *ref* is empty, let *inv-quals* be *cv*`&`,

(2.2) — otherwise, let *inv-quals* be *cv ref*.

22.10.17.5.2 Class template `copyable_function` [func.wrap.copy.class]

```
namespace std {
  template<class R, class... ArgTypes>
  class copyable_function<R(ArgTypes...) cv ref noexcept(noex)> {
  public:
    using result_type = R;

    // 22.10.17.5.3, constructors, assignments, and destructor
    copyable_function() noexcept;
    copyable_function(nullptr_t) noexcept;
    copyable_function(const copyable_function&);
    copyable_function(copyable_function&&) noexcept;
    template<class F> copyable_function(F&&);
    template<class T, class... Args>
      explicit copyable_function(in_place_type_t<T>, Args&&...);
    template<class T, class U, class... Args>
      explicit copyable_function(in_place_type_t<T>, initializer_list<U>, Args&&...);

    copyable_function& operator=(const copyable_function&);
    copyable_function& operator=(copyable_function&&);
    copyable_function& operator=(nullptr_t) noexcept;
    template<class F> copyable_function& operator=(F&&);

    ~copyable_function();

    // 22.10.17.5.4, invocation
    explicit operator bool() const noexcept;
    R operator()(ArgTypes...) cv ref noexcept(noex);

    // 22.10.17.5.5, utility
    void swap(copyable_function&) noexcept;
    friend void swap(copyable_function&, copyable_function&) noexcept;
    friend bool operator==(const copyable_function&, nullptr_t) noexcept;
```

```
  private:
    template<class VT>
      static constexpr bool is-callable-from = see below;        // exposition only
  };
}
```

1 The `copyable_function` class template provides polymorphic wrappers that generalize the notion of a callable object (22.10.3). These wrappers can store, copy, move, and call arbitrary callable objects, given a call signature.

2 *Recommended practice*: Implementations should avoid the use of dynamically allocated memory for a small contained value.

[*Note 1*: Such small-object optimization can only be applied to a type `T` for which `is_nothrow_move_constructible_v<T>` is `true`. — *end note*]

22.10.17.5.3 Constructors, assignments, and destructor [func.wrap.copy.ctor]

```
template<class VT>
  static constexpr bool is-callable-from = see below;
```

1 If *noex* is `true`, *is-callable-from*`<VT>` is equal to:

```
is_nothrow_invocable_r_v<R, VT cv ref, ArgTypes...> &&
is_nothrow_invocable_r_v<R, VT inv-quals, ArgTypes...>
```

Otherwise, *is-callable-from*`<VT>` is equal to:

```
is_invocable_r_v<R, VT cv ref, ArgTypes...> &&
is_invocable_r_v<R, VT inv-quals, ArgTypes...>
```

```
copyable_function() noexcept;
copyable_function(nullptr_t) noexcept;
```

2 *Postconditions*: `*this` has no target object.

```
copyable_function(const copyable_function& f);
```

3 *Postconditions*: `*this` has no target object if `f` had no target object. Otherwise, the target object of `*this` is a copy of the target object of `f`.

4 *Throws*: Any exception thrown by the initialization of the target object. May throw `bad_alloc`.

```
copyable_function(copyable_function&& f) noexcept;
```

5 *Postconditions*: The target object of `*this` is the target object `f` had before construction, and `f` is in a valid state with an unspecified value.

```
template<class F> copyable_function(F&& f);
```

6 Let `VT` be `decay_t<F>`.

7 *Constraints*:

(7.1) — `remove_cvref_t<F>` is not the same type as `copyable_function`, and

(7.2) — `remove_cvref_t<F>` is not a specialization of `in_place_type_t`, and

(7.3) — *is-callable-from*`<VT>` is `true`.

8 *Mandates*:

(8.1) — `is_constructible_v<VT, F>` is `true`, and

(8.2) — `is_copy_constructible_v<VT>` is `true`.

9 *Preconditions*: `VT` meets the *Cpp17Destructible* and *Cpp17CopyConstructible* requirements.

10 *Postconditions*: `*this` has no target object if any of the following hold:

(10.1) — `f` is a null function pointer value, or

(10.2) — `f` is a null member pointer value, or

(10.3) — `remove_cvref_t<F>` is a specialization of the `copyable_function` class template, and `f` has no target object.

Otherwise, `*this` has a target object of type `VT` direct-non-list-initialized with `std::forward<F>(f)`.

11 *Throws*: Any exception thrown by the initialization of the target object. May throw `bad_alloc` unless `VT` is a function pointer or a specialization of `reference_wrapper`.

```
template<class T, class... Args>
  explicit copyable_function(in_place_type_t<T>, Args&&... args);
```

12 Let `VT` be `decay_t<T>`.

13 *Constraints*:

(13.1) — `is_constructible_v<VT, Args...>` is `true`, and

(13.2) — *`is-callable-from`*`<VT>` is `true`.

14 *Mandates*:

(14.1) — `VT` is the same type as `T`, and

(14.2) — `is_copy_constructible_v<VT>` is `true`.

15 *Preconditions*: `VT` meets the *Cpp17Destructible* and *Cpp17CopyConstructible* requirements.

16 *Postconditions*: `*this` has a target object of type `VT` direct-non-list-initialized with `std::forward<Args>(args)...`.

17 *Throws*: Any exception thrown by the initialization of the target object. May throw `bad_alloc` unless `VT` is a pointer or a specialization of `reference_wrapper`.

```
template<class T, class U, class... Args>
  explicit copyable_function(in_place_type_t<T>, initializer_list<U> ilist, Args&&... args);
```

18 Let `VT` be `decay_t<T>`.

19 *Constraints*:

(19.1) — `is_constructible_v<VT, initializer_list<U>&, Args...>` is `true`, and

(19.2) — *`is-callable-from`*`<VT>` is `true`.

20 *Mandates*:

(20.1) — `VT` is the same type as `T`, and

(20.2) — `is_copy_constructible_v<VT>` is `true`.

21 *Preconditions*: `VT` meets the *Cpp17Destructible* and *Cpp17CopyConstructible* requirements.

22 *Postconditions*: `*this` has a target object of type `VT` direct-non-list-initialized with `ilist, std::forward<Args>(args)...`.

23 *Throws*: Any exception thrown by the initialization of the target object. May throw `bad_alloc` unless `VT` is a pointer or a specialization of `reference_wrapper`.

```
copyable_function& operator=(const copyable_function& f);
```

24 *Effects*: Equivalent to: `copyable_function(f).swap(*this);`

25 *Returns*: `*this`.

```
copyable_function& operator=(copyable_function&& f);
```

26 *Effects*: Equivalent to: `copyable_function(std::move(f)).swap(*this);`

27 *Returns*: `*this`.

```
copyable_function& operator=(nullptr_t) noexcept;
```

28 *Effects*: Destroys the target object of `*this`, if any.

29 *Returns*: `*this`.

```
template<class F> copyable_function& operator=(F&& f);
```

30 *Effects*: Equivalent to: `copyable_function(std::forward<F>(f)).swap(*this);`

31 *Returns*: `*this`.

```
~copyable_function();
```

32 *Effects*: Destroys the target object of `*this`, if any.

22.10.17.5.4 Invocation [func.wrap.copy.inv]

```
explicit operator bool() const noexcept;
```

1 *Returns*: `true` if `*this` has a target object, otherwise `false`.

```
R operator()(ArgTypes... args) cv ref noexcept(noex);
```

2 *Preconditions*: `*this` has a target object.

3 *Effects*: Equivalent to:

```
return INVOKE<R>(static_cast<F inv-quals>(f), std::forward<ArgTypes>(args)...);
```

where `f` is an lvalue designating the target object of `*this` and `F` is the type of `f`.

22.10.17.5.5 Utility [func.wrap.copy.util]

```
void swap(copyable_function& other) noexcept;
```

1 *Effects*: Exchanges the target objects of `*this` and `other`.

```
friend void swap(copyable_function& f1, copyable_function& f2) noexcept;
```

2 *Effects*: Equivalent to `f1.swap(f2)`.

```
friend bool operator==(const copyable_function& f, nullptr_t) noexcept;
```

3 *Returns*: `true` if `f` has no target object, otherwise `false`.

22.10.17.6 Non-owning wrapper [func.wrap.ref]

22.10.17.6.1 General [func.wrap.ref.general]

1 The header provides partial specializations of `function_ref` for each combination of the possible replacements of the placeholders *cv* and *noex* where:

(1.1) — *cv* is either const or empty, and

(1.2) — *noex* is either `true` or `false`.

22.10.17.6.2 Class template function_ref [func.wrap.ref.class]

```
namespace std {
  template<class R, class... ArgTypes>
  class function_ref<R(ArgTypes...) cv noexcept(noex)> {
  public:
    // 22.10.17.6.3, constructors and assignment operators
    template<class F> function_ref(F*) noexcept;
    template<class F> constexpr function_ref(F&&) noexcept;
    template<auto c, class F> constexpr function_ref(constant_wrapper<c, F>) noexcept;
    template<auto c, class F, class U>
      constexpr function_ref(constant_wrapper<c, F>, U&&) noexcept;
    template<auto c, class F, class T>
      constexpr function_ref(constant_wrapper<c, F>, cv T*) noexcept;

    constexpr function_ref(const function_ref&) noexcept = default;
    constexpr function_ref& operator=(const function_ref&) noexcept = default;
    template<class T> function_ref& operator=(T) = delete;

    // 22.10.17.6.4, invocation
    R operator()(ArgTypes...) const noexcept(noex);

  private:
    template<class... T>
      static constexpr bool is-invocable-using = see below;          // exposition only
```

```
    R (*thunk-ptr)(BoundEntityType, ArgTypes&&...) noexcept(noex);      // exposition only
    BoundEntityType bound-entity;                                       // exposition only
  };

  // 22.10.17.6.5, deduction guides
  template<class F>
    function_ref(F*) -> function_ref<F>;
  template<auto c, class F0>
    function_ref(constant_wrapper<c, F0>) -> function_ref<see below>;
  template<auto c, class F, class T>
    function_ref(constant_wrapper<c, F>, T&&) -> function_ref<see below>;
}
```

1 An object of class `function_ref<R(Args...) cv noexcept(noex)>` stores a pointer to function *thunk-ptr* and an object *bound-entity*. The object *bound-entity* has an unspecified trivially copyable type *BoundEntityType*, that models `copyable` and is capable of storing a pointer to object value or a pointer to function value. The type of *thunk-ptr* is `R(*)(BoundEntityType, Args&&...) noexcept(noex)`.

2 Each specialization of `function_ref` is a trivially copyable type (6.9.1) that models `copyable`.

3 Within subclause 22.10.17.6, *call-args* is an argument pack with elements such that

`decltype((call-args))...`

denote `ArgTypes&&...` respectively.

22.10.17.6.3 Constructors and assignment operators [func.wrap.ref.ctor]

```
template<class... T>
  static constexpr bool is-invocable-using = see below;
```

1 If *noex* is `true`, *is-invocable-using*`<T...>` is equal to:

`is_nothrow_invocable_r_v<R, T..., ArgTypes...>`

Otherwise, *is-invocable-using*`<T...>` is equal to:

`is_invocable_r_v<R, T..., ArgTypes...>`

```
template<class F>
  static constexpr bool is-convertible-from-specialization = see below;
```

2 If `F` denotes a specialization `function_ref<R(Args...) cv2 noexcept(noex2)>` for some placeholders *cv2* and *noex2*, *is-convertible-from-specialization*`<F>` is equal to:

`is_convertible_v<R(&)(Args...) noexcept(noex2), R(&)(Args...) noexcept(noex)> &&`
`is_convertible_v<int cv&, int cv2&>.`

Otherwise, *is-convertible-from-specialization*`<F>` is `false`.

```
template<class F> function_ref(F* f) noexcept;
```

3 *Constraints*:

(3.1) — `is_function_v<F>` is `true`, and

(3.2) — *is-invocable-using*`<F>` is `true`.

4 *Preconditions*: `f` is not a null pointer.

5 *Effects*: Initializes *bound-entity* with `f`, and *thunk-ptr* with the address of a function *thunk* such that *thunk*`(`*bound-entity*`, `*call-args*`...)` is expression-equivalent (3.22) to `invoke_r<R>(f, `*call-args*`...)`.

```
template<class F> constexpr function_ref(F&& f) noexcept;
```

6 Let `T` be `remove_reference_t<F>`.

7 *Constraints*:

(7.1) — `remove_cvref_t<F>` is not the same type as `function_ref`,

(7.2) — `is_member_pointer_v<T>` is `false`, and

(7.3) — *is-invocable-using*`<cv T&>` is `true`.

8 *Effects*: If *is-convertible-from-specialization*<remove_cv_t<T>> is false, initializes *bound-entity* with addressof(f), and *thunk-ptr* with the address of a function *thunk* such that *thunk*(*bound-entity*, *call-args*...) is expression-equivalent (3.22) to invoke_r<R>(static_cast<*cv* T&>(f), *call-args*...). Otherwise, initializes *bound-entity* with the value of f.*bound-entity* and *thunk-ptr* with the value of f.*thunk-ptr*.

9 *Remarks*: If remove_cvref_t<F> is a specialization of function_ref, an implementation may initialize *bound-entity* with the value of f.*bound-entity* and *thunk-ptr* with the value of f.*thunk-ptr*.

[*Example 1*:

```
void f1(std::string);
void f2(std::string);

function_ref<void(std::string)> r1(&f1);
function_ref<void(std::string&&)> r2(r1);
r2("");                  // f1 is invoked
r1 = &f2;
r2("");                  // it is unspecified if f1 or f2 is invoked
```

— *end example*]

```
template<auto c, class F> constexpr function_ref(constant_wrapper<c, F> f) noexcept;
```

10 *Constraints*: *is-invocable-using*<const F&> is true.

11 *Mandates*:

(11.1) — If is_pointer_v<F> || is_member_pointer_v<F> is true, then f.value != nullptr is true, and

(11.2) — if ArgTypes is not an empty pack and all types in remove_cvref_t<ArgTypes>... satisfy *constexpr-param* then constant_wrapper<*INVOKE*(f.value, remove_cvref_t<ArgTypes>::value...)> is not a valid type.

12 *Effects*: Initializes *bound-entity* with a pointer to an unspecified object or null pointer value, and *thunk-ptr* with the address of a function *thunk* such that *thunk*(*bound-entity*, *call-args*...) is expression-equivalent (3.22) to invoke_r<R>(f.value, *call-args*...).

```
template<auto c, class F, class U>
  constexpr function_ref(constant_wrapper<c, F> f, U&& obj) noexcept;
```

13 Let T be remove_reference_t<U>.

14 *Constraints*:

(14.1) — is_rvalue_reference_v<U&&> is false, and

(14.2) — *is-invocable-using*<const F&, *cv* T&> is true.

15 *Mandates*: If is_pointer_v<F> || is_member_pointer_v<F> is true, then f.value != nullptr is true.

16 *Effects*: Initializes *bound-entity* with addressof(obj), and *thunk-ptr* with the address of a function *thunk* such that *thunk*(*bound-entity*, *call-args*...) is expression-equivalent (3.22) to invoke_r<R>(f.value, static_cast<*cv* T&>(obj), *call-args*...).

```
template<auto c, class F>
  constexpr function_ref(constant_wrapper<c, F> f, cv T* obj) noexcept;
```

17 *Constraints*: *is-invocable-using*<const F&, *cv* T*> is true.

18 *Mandates*: If is_pointer_v<F> || is_member_pointer_v<F> is true, then f.value != nullptr is true.

19 *Preconditions*: If is_member_pointer_v<F> is true, obj is not a null pointer.

20 *Effects*: Initializes *bound-entity* with obj, and *thunk-ptr* with the address of a function *thunk* such that *thunk*(*bound-entity*, *call-args*...) is expression-equivalent (3.22) to invoke_r<R>(f.value, obj, *call-args*...).

```
template<class T> function_ref& operator=(T) = delete;
```

21 *Constraints*:

(21.1) — *is-convertible-from-specialization*<T> is false,

(21.2) — is_pointer_v<T> is false, and

(21.3) — T is not a specialization of constant_wrapper.

22.10.17.6.4 Invocation [func.wrap.ref.inv]

```
R operator()(ArgTypes... args) const noexcept(noex);
```

1 *Effects*: Equivalent to: return *thunk-ptr*(*bound-entity*, std::forward<ArgTypes>(args)...);

22.10.17.6.5 Deduction guides [func.wrap.ref.deduct]

```
template<class F>
  function_ref(F*) -> function_ref<F>;
```

1 *Constraints*: is_function_v<F> is true.

```
template<auto c, class F0>
  function_ref(constant_wrapper<c, F0>) -> function_ref<see below>;
```

2 Let F be remove_pointer_t<F0>.

3 *Constraints*: is_function_v<F> is true.

4 *Remarks*: The deduced type is function_ref<F>.

```
template<auto c, class F, class T>
  function_ref(constant_wrapper<c, F>, T&&) -> function_ref<see below>;
```

5 *Constraints*:

(5.1) — F is of the form R(G::*)(A...) *cv* &$_{opt}$ noexcept(E) for a type G, or

(5.2) — F is of the form M G::* for a type G and an object type M, in which case let R be invoke_result_t<F, T&>, A... be an empty pack, and E be true, or

(5.3) — F is of the form R(*)(G, A...) noexcept(E) for a type G.

6 *Remarks*: The deduced type is function_ref<R(A...) noexcept(E)>.

22.10.18 Searchers [func.search]

22.10.18.1 General [func.search.general]

1 Subclause 22.10.18 provides function object types (22.10) for operations that search for a sequence [pat_first, pat_last) in another sequence [first, last) that is provided to the object's function call operator. The first sequence (the pattern to be searched for) is provided to the object's constructor, and the second (the sequence to be searched) is provided to the function call operator.

2 Each specialization of a class template specified in 22.10.18 shall meet the *Cpp17CopyConstructible* and *Cpp17CopyAssignable* requirements. Template parameters named

(2.1) — ForwardIterator,

(2.2) — ForwardIterator1,

(2.3) — ForwardIterator2,

(2.4) — RandomAccessIterator,

(2.5) — RandomAccessIterator1,

(2.6) — RandomAccessIterator2, and

(2.7) — BinaryPredicate

of templates specified in 22.10.18 shall meet the same requirements and semantics as specified in 26.1. Template parameters named Hash shall meet the *Cpp17Hash* requirements (Table 37).

3 The Boyer-Moore searcher implements the Boyer-Moore search algorithm. The Boyer-Moore-Horspool searcher implements the Boyer-Moore-Horspool search algorithm. In general, the Boyer-Moore searcher will use more memory and give better runtime performance than Boyer-Moore-Horspool.

22.10.18.2 Class template `default_searcher` [func.search.default]

```
namespace std {
  template<class ForwardIterator1, class BinaryPredicate = equal_to<>>
  class default_searcher {
  public:
    constexpr default_searcher(ForwardIterator1 pat_first, ForwardIterator1 pat_last,
                               BinaryPredicate pred = BinaryPredicate());

    template<class ForwardIterator2>
      constexpr pair<ForwardIterator2, ForwardIterator2>
        operator()(ForwardIterator2 first, ForwardIterator2 last) const;

  private:
    ForwardIterator1 pat_first_;        // exposition only
    ForwardIterator1 pat_last_;         // exposition only
    BinaryPredicate pred_;              // exposition only
  };
}
```

```
constexpr default_searcher(ForwardIterator1 pat_first, ForwardIterator1 pat_last,
                           BinaryPredicate pred = BinaryPredicate());
```

1 *Effects*: Constructs a `default_searcher` object, initializing `pat_first_` with `pat_first`, `pat_last_` with `pat_last`, and `pred_` with `pred`.

2 *Throws*: Any exception thrown by the copy constructor of `BinaryPredicate` or `ForwardIterator1`.

```
template<class ForwardIterator2>
  constexpr pair<ForwardIterator2, ForwardIterator2>
    operator()(ForwardIterator2 first, ForwardIterator2 last) const;
```

3 *Effects*: Returns a pair of iterators `i` and `j` such that

(3.1) — `i == search(first, last, pat_first_, pat_last_, pred_)`, and

(3.2) — if `i == last`, then `j == last`, otherwise `j == next(i, distance(pat_first_, pat_last_))`.

22.10.18.3 Class template `boyer_moore_searcher` [func.search.bm]

```
namespace std {
  template<class RandomAccessIterator1,
           class Hash = hash<typename iterator_traits<RandomAccessIterator1>::value_type>,
           class BinaryPredicate = equal_to<>>
  class boyer_moore_searcher {
  public:
    boyer_moore_searcher(RandomAccessIterator1 pat_first,
                         RandomAccessIterator1 pat_last,
                         Hash hf = Hash(),
                         BinaryPredicate pred = BinaryPredicate());

    template<class RandomAccessIterator2>
      pair<RandomAccessIterator2, RandomAccessIterator2>
        operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

  private:
    RandomAccessIterator1 pat_first_;   // exposition only
    RandomAccessIterator1 pat_last_;    // exposition only
    Hash hash_;                         // exposition only
    BinaryPredicate pred_;              // exposition only
  };
}
```

```
boyer_moore_searcher(RandomAccessIterator1 pat_first,
                     RandomAccessIterator1 pat_last,
                     Hash hf = Hash(),
                     BinaryPredicate pred = BinaryPredicate());
```

1 *Preconditions*: The value type of `RandomAccessIterator1` meets the *Cpp17DefaultConstructible*,

Cpp17CopyConstructible, and *Cpp17CopyAssignable* requirements.

2 Let `V` be `iterator_traits<RandomAccessIterator1>::value_type`. For any two values `A` and `B` of type `V`, if `pred(A, B) == true`, then `hf(A) == hf(B)` is `true`.

3 *Effects*: Initializes `pat_first_` with `pat_first`, `pat_last_` with `pat_last`, `hash_` with `hf`, and `pred_` with `pred`.

4 *Throws*: Any exception thrown by the copy constructor of `RandomAccessIterator1`, or by the default constructor, copy constructor, or the copy assignment operator of the value type of `RandomAccessIterator1`, or the copy constructor or `operator()` of `BinaryPredicate` or `Hash`. May throw `bad_alloc` if additional memory needed for internal data structures cannot be allocated.

```
template<class RandomAccessIterator2>
  pair<RandomAccessIterator2, RandomAccessIterator2>
    operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;
```

5 *Mandates*: `RandomAccessIterator1` and `RandomAccessIterator2` have the same value type.

6 *Effects*: Finds a subsequence of equal values in a sequence.

7 *Returns*: A pair of iterators `i` and `j` such that

(7.1) — `i` is the first iterator in the range [`first`, `last - (pat_last_ - pat_first_)`) such that for every non-negative integer `n` less than `pat_last_ - pat_first_` the following condition holds: `pred(*(i + n), *(pat_first_ + n)) != false`, and

(7.2) — `j == next(i, distance(pat_first_, pat_last_))`.

Returns `make_pair(first, first)` if [`pat_first_`, `pat_last_`) is empty, otherwise returns `make_pair(last, last)` if no such iterator is found.

8 *Complexity*: At most `(last - first) * (pat_last_ - pat_first_)` applications of the predicate.

22.10.18.4 Class template `boyer_moore_horspool_searcher` [func.search.bmh]

```
namespace std {
  template<class RandomAccessIterator1,
           class Hash = hash<typename iterator_traits<RandomAccessIterator1>::value_type>,
           class BinaryPredicate = equal_to<>>
  class boyer_moore_horspool_searcher {
  public:
    boyer_moore_horspool_searcher(RandomAccessIterator1 pat_first,
                                  RandomAccessIterator1 pat_last,
                                  Hash hf = Hash(),
                                  BinaryPredicate pred = BinaryPredicate());

    template<class RandomAccessIterator2>
      pair<RandomAccessIterator2, RandomAccessIterator2>
        operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

  private:
    RandomAccessIterator1 pat_first_;   // exposition only
    RandomAccessIterator1 pat_last_;    // exposition only
    Hash hash_;                         // exposition only
    BinaryPredicate pred_;              // exposition only
  };
}

boyer_moore_horspool_searcher(RandomAccessIterator1 pat_first,
                              RandomAccessIterator1 pat_last,
                              Hash hf = Hash(),
                              BinaryPredicate pred = BinaryPredicate());
```

1 *Preconditions*: The value type of `RandomAccessIterator1` meets the *Cpp17DefaultConstructible*, *Cpp17CopyConstructible*, and *Cpp17CopyAssignable* requirements.

2 Let `V` be `iterator_traits<RandomAccessIterator1>::value_type`. For any two values `A` and `B` of type `V`, if `pred(A, B) == true`, then `hf(A) == hf(B)` is `true`.

3 *Effects*: Initializes `pat_first_` with `pat_first`, `pat_last_` with `pat_last`, `hash_` with `hf`, and `pred_` with `pred`.

4 *Throws*: Any exception thrown by the copy constructor of `RandomAccessIterator1`, or by the default constructor, copy constructor, or the copy assignment operator of the value type of `RandomAccessIterator1`, or the copy constructor or `operator()` of `BinaryPredicate` or `Hash`. May throw `bad_alloc` if additional memory needed for internal data structures cannot be allocated.

```
template<class RandomAccessIterator2>
  pair<RandomAccessIterator2, RandomAccessIterator2>
    operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;
```

5 *Mandates*: `RandomAccessIterator1` and `RandomAccessIterator2` have the same value type.

6 *Effects*: Finds a subsequence of equal values in a sequence.

7 *Returns*: A pair of iterators `i` and `j` such that

(7.1) — `i` is the first iterator in the range [`first`, `last - (pat_last_ - pat_first_)`) such that for every non-negative integer `n` less than `pat_last_ - pat_first_` the following condition holds: `pred(*(i + n), *(pat_first_ + n)) != false`, and

(7.2) — `j == next(i, distance(pat_first_, pat_last_))`.

Returns `make_pair(first, first)` if [`pat_first_`, `pat_last_`) is empty, otherwise returns `make_pair(last, last)` if no such iterator is found.

8 *Complexity*: At most `(last - first) * (pat_last_ - pat_first_)` applications of the predicate.

22.10.19 Class template `hash` [unord.hash]

1 The unordered associative containers defined in 23.5 use specializations of the class template `hash` (22.10.2) as the default hash function.

2 Each specialization of `hash` is either enabled or disabled, as described below.

[*Note 1*: Enabled specializations meet the *Cpp17Hash* requirements, and disabled specializations do not. — *end note*]

Each header that declares the template `hash` provides enabled specializations of `hash` for `nullptr_t` and all cv-unqualified arithmetic, enumeration, and pointer types. For any type `Key` for which neither the library nor the user provides an explicit or partial specialization of the class template `hash`, `hash<Key>` is disabled.

3 If the library provides an explicit or partial specialization of `hash<Key>`, that specialization is enabled except as noted otherwise, and its member functions are `noexcept` except as noted otherwise.

4 If `H` is a disabled specialization of `hash`, these values are `false`: `is_default_constructible_v<H>`, `is_copy_constructible_v<H>`, `is_move_constructible_v<H>`, `is_copy_assignable_v<H>`, and `is_move_assignable_v<H>`. Disabled specializations of `hash` are not function object types (22.10).

[*Note 2*: This means that the specialization of `hash` exists, but any attempts to use it as a *Cpp17Hash* will be ill-formed. — *end note*]

5 An enabled specialization `hash<Key>` will:

(5.1) — meet the *Cpp17Hash* requirements (Table 37), with `Key` as the function call argument type, the *Cpp17DefaultConstructible* requirements (Table 30), the *Cpp17CopyAssignable* requirements (Table 34), the *Cpp17Swappable* requirements (16.4.4.3),

(5.2) — meet the requirement that if `k1 == k2` is `true`, `h(k1) == h(k2)` is also `true`, where `h` is an object of type `hash<Key>` and `k1` and `k2` are objects of type `Key`;

(5.3) — meet the requirement that the expression `h(k)`, where `h` is an object of type `hash<Key>` and `k` is an object of type `Key`, shall not throw an exception unless `hash<Key>` is a program-defined specialization.

22.11 Bit manipulation [bit]

22.11.1 General [bit.general]

1 The header `<bit>` provides components to access, manipulate and process both individual bits and bit sequences.

22.11.2 Header <bit> synopsis [bit.syn]

```
// all freestanding
namespace std {
  // 22.11.3, bit_cast
  template<class To, class From>
    constexpr To bit_cast(const From& from) noexcept;

  // 22.11.4, byteswap
  template<class T>
    constexpr T byteswap(T value) noexcept;

  // 22.11.5, integral powers of 2
  template<class T>
    constexpr bool has_single_bit(T x) noexcept;
  template<class T>
    constexpr T bit_ceil(T x);
  template<class T>
    constexpr T bit_floor(T x) noexcept;
  template<class T>
    constexpr int bit_width(T x) noexcept;

  // 22.11.6, rotating
  template<class T>
    constexpr T rotl(T x, int s) noexcept;
  template<class T>
    constexpr T rotr(T x, int s) noexcept;

  // 22.11.7, counting
  template<class T>
    constexpr int countl_zero(T x) noexcept;
  template<class T>
    constexpr int countl_one(T x) noexcept;
  template<class T>
    constexpr int countr_zero(T x) noexcept;
  template<class T>
    constexpr int countr_one(T x) noexcept;
  template<class T>
    constexpr int popcount(T x) noexcept;

  // 22.11.8, endian
  enum class endian {
    little = see below,
    big    = see below,
    native = see below
  };
}
```

22.11.3 Function template bit_cast [bit.cast]

```
template<class To, class From>
  constexpr To bit_cast(const From& from) noexcept;
```

1 *Constraints*:

(1.1) — `sizeof(To) == sizeof(From)` is `true`;

(1.2) — `is_trivially_copyable_v<To>` is `true`; and

(1.3) — `is_trivially_copyable_v<From>` is `true`.

2 *Mandates*: Neither `To` nor `From` are consteval-only types (6.9.1).

3 *Constant When*: Neither `To` nor `From` has constexpr-unknown representation (7.7.2).

4 *Returns*: An object of type `To`. Implicitly creates objects nested within the result (6.8.2). Each bit of the value representation of the result is equal to the corresponding bit in the object representation of `from`. Padding bits of the result are unspecified. For the result and each object created within

it, if there is no value of the object's type corresponding to the value representation produced, the behavior is undefined. If there are multiple such values, which value is produced is unspecified. A bit in the value representation of the result is indeterminate if it does not correspond to a bit in the value representation of `from` or corresponds to a bit for which the smallest enclosing object is not within its lifetime or has an indeterminate value (6.8.5). A bit in the value representation of the result is erroneous if it corresponds to a bit for which the smallest enclosing object has an erroneous value. For each bit b in the value representation of the result that is indeterminate or erroneous, let u be the smallest object containing that bit enclosing b:

(4.1) — If u is of unsigned ordinary character type or `std::byte` type, u has an indeterminate value if any of the bits in its value representation are indeterminate, or otherwise has an erroneous value.

(4.2) — Otherwise, if b is indeterminate, the behavior is undefined.

(4.3) — Otherwise, the behavior is erroneous, and the result is as specified above.

The result does not otherwise contain any indeterminate or erroneous values.

22.11.4 `byteswap` [bit.byteswap]

```
template<class T>
  constexpr T byteswap(T value) noexcept;
```

1 *Constraints*: `T` models `integral`.

2 *Mandates*: `T` does not have padding bits (6.9.1).

3 Let the sequence R comprise the bytes of the object representation of `value` in reverse order.

4 *Returns*: An object `v` of type `T` such that each byte in the object representation of `v` is equal to the byte in the corresponding position in R.

22.11.5 Integral powers of 2 [bit.pow.two]

```
template<class T>
  constexpr bool has_single_bit(T x) noexcept;
```

1 *Constraints*: `T` is an unsigned integer type (6.9.2).

2 *Returns*: `true` if `x` is an integral power of two; `false` otherwise.

```
template<class T>
  constexpr T bit_ceil(T x);
```

3 Let N be the smallest power of 2 greater than or equal to `x`.

4 *Constraints*: `T` is an unsigned integer type (6.9.2).

5 *Preconditions*: N is representable as a value of type `T`.

6 *Returns*: N.

7 *Throws*: Nothing.

8 *Remarks*: A function call expression that violates the precondition in the *Preconditions*: element is not a core constant expression (7.7.2).

```
template<class T>
  constexpr T bit_floor(T x) noexcept;
```

9 *Constraints*: `T` is an unsigned integer type (6.9.2).

10 *Returns*: If `x == 0`, `0`; otherwise the maximal value `y` such that `has_single_bit(y)` is `true` and `y <= x`.

```
template<class T>
  constexpr int bit_width(T x) noexcept;
```

11 *Constraints*: `T` is an unsigned integer type (6.9.2).

12 *Returns*: If `x == 0`, `0`; otherwise one plus the base-2 logarithm of `x`, with any fractional part discarded.

22.11.6 Rotating [bit.rotate]

1 In the following descriptions, let `N` denote `numeric_limits<T>::digits`.

```
template<class T>
  constexpr T rotl(T x, int s) noexcept;
```

2 *Constraints*: `T` is an unsigned integer type (6.9.2).

3 Let `r` be `s % N`.

4 *Returns*: If `r` is `0`, `x`; if `r` is positive, `(x << r) | (x >> (N - r))`; if `r` is negative, `rotr(x, -r)`.

```
template<class T>
  constexpr T rotr(T x, int s) noexcept;
```

5 *Constraints*: `T` is an unsigned integer type (6.9.2).

6 Let `r` be `s % N`.

7 *Returns*: If `r` is `0`, `x`; if `r` is positive, `(x >> r) | (x << (N - r))`; if `r` is negative, `rotl(x, -r)`.

22.11.7 Counting [bit.count]

1 In the following descriptions, let `N` denote `numeric_limits<T>::digits`.

```
template<class T>
  constexpr int countl_zero(T x) noexcept;
```

2 *Constraints*: `T` is an unsigned integer type (6.9.2).

3 *Returns*: The number of consecutive `0` bits in the value of `x`, starting from the most significant bit.
[*Note 1*: Returns `N` if `x == 0`. — *end note*]

```
template<class T>
  constexpr int countl_one(T x) noexcept;
```

4 *Constraints*: `T` is an unsigned integer type (6.9.2).

5 *Returns*: The number of consecutive `1` bits in the value of `x`, starting from the most significant bit.
[*Note 2*: Returns `N` if `x == numeric_limits<T>::max()`. — *end note*]

```
template<class T>
  constexpr int countr_zero(T x) noexcept;
```

6 *Constraints*: `T` is an unsigned integer type (6.9.2).

7 *Returns*: The number of consecutive `0` bits in the value of `x`, starting from the least significant bit.
[*Note 3*: Returns `N` if `x == 0`. — *end note*]

```
template<class T>
  constexpr int countr_one(T x) noexcept;
```

8 *Constraints*: `T` is an unsigned integer type (6.9.2).

9 *Returns*: The number of consecutive `1` bits in the value of `x`, starting from the least significant bit.
[*Note 4*: Returns `N` if `x == numeric_limits<T>::max()`. — *end note*]

```
template<class T>
  constexpr int popcount(T x) noexcept;
```

10 *Constraints*: `T` is an unsigned integer type (6.9.2).

11 *Returns*: The number of `1` bits in the value of `x`.

22.11.8 Endian [bit.endian]

1 Two common methods of byte ordering in multibyte scalar types are big-endian and little-endian in the execution environment. Big-endian is a format for storage of binary data in which the most significant byte is placed first, with the rest in descending order. Little-endian is a format for storage of binary data in which the least significant byte is placed first, with the rest in ascending order. This subclause describes the endianness of the scalar types of the execution environment.

```
enum class endian {
  little = see below,
  big    = see below,
  native = see below
};
```

2 If all scalar types have size 1 byte, then all of `endian::little`, `endian::big`, and `endian::native` have the same value. Otherwise, `endian::little` is not equal to `endian::big`. If all scalar types are big-endian, `endian::native` is equal to `endian::big`. If all scalar types are little-endian, `endian::native` is equal to `endian::little`. Otherwise, `endian::native` is not equal to either `endian::big` or `endian::little`.

```

[1] For a function template whose return type is not specified above, the return type is an implementation-defined unsigned integer type large enough to represent all possible result values. Each function template has the same semantics as the corresponding type-generic function with the same name specified in SEE ALSO: ISO/IEC 9899:2024, 7.18.

[2] *Mandates*: `T` is an unsigned integer type.

[3] Otherwise, the contents and meaning of the header `<stdbit.h>` are the same as the C standard library header `<stdbit.h>`.

See also: ISO/IEC 9899:2024, 7.18

23 Containers library [containers]

23.1 General [containers.general]

1 This Clause describes components that C++ programs may use to organize collections of information.

2 The following subclauses describe container requirements, and components for sequence containers and associative containers, as summarized in Table 74.

Table 74 — Containers library summary [tab:containers.summary]

	Subclause	Header
23.2	Requirements	
23.3	Sequence containers	`<array>`, `<deque>`, `<forward_list>`, `<hive>`, `<inplace_vector>`, `<list>`, `<vector>`
23.4	Associative containers	`<map>`, `<set>`
23.5	Unordered associative containers	`<unordered_map>`, `<unordered_set>`
23.6	Container adaptors	`<queue>`, `<stack>`, `<flat_map>`, `<flat_set>`
23.7	Views	`<span>`, `<mdspan>`

23.2 Requirements [container.requirements]

23.2.1 Preamble [container.requirements.pre]

1 Containers are objects that store other objects. They control allocation and deallocation of these objects through constructors, destructors, insert and erase operations.

2 All of the complexity requirements in this Clause are stated solely in terms of the number of operations on the contained objects.

[*Example 1*: The copy constructor of type `vector<vector<int>>` has linear complexity, even though the complexity of copying each contained `vector<int>` is itself linear. — *end example*]

3 Allocator-aware containers (23.2.2.5) other than `basic_string` construct elements using the function `allocator_traits<allocator_type>::rebind_traits<U>::construct` and destroy elements using the function `allocator_traits<allocator_type>::rebind_traits<U>::destroy` (20.2.9.3), where `U` is either `allocator_type::value_type` or an internal type used by the container. These functions are called only for the container's element type, not for internal types used by the container.

[*Note 1*: This means, for example, that a node-based container would need to construct nodes containing aligned buffers and call `construct` to place the element into the buffer. — *end note*]

23.2.2 General containers [container.requirements.general]

23.2.2.1 Introduction [container.intro.reqmts]

1 In 23.2.2,

(1.1) — `X` denotes a container class containing objects of type `T`,

(1.2) — `a` denotes a value of type `X`,

(1.3) — `b` and `c` denote values of type (possibly const) `X`,

(1.4) — `i` and `j` denote values of type (possibly const) `X::iterator`,

(1.5) — `u` denotes an identifier,

(1.6) — `v` denotes an lvalue of type (possibly const) `X` or an rvalue of type `const X`,

(1.7) — `s` and `t` denote non-const lvalues of type `X`, and

(1.8) — `rv` denotes a non-const rvalue of type `X`.

2 The following exposition-only concept is used in the definition of containers:

```
template<class R, class T>
concept container-compatible-range =     // exposition only
  ranges::input_range<R> && convertible_to<ranges::range_reference_t<R>, T>;
```

23.2.2.2 Container requirements [container.reqmts]

1 A type `X` meets the *container* requirements if the following types, statements, and expressions are well-formed and have the specified semantics.

`typename X::value_type`

2 *Result*: `T`

3 *Preconditions*: `T` is *Cpp17Erasable* from `X` (see 23.2.2.5, below).

`typename X::reference`

4 *Result*: `T&`

`typename X::const_reference`

5 *Result*: `const T&`

`typename X::iterator`

6 *Result*: A type that meets the forward iterator requirements (24.3.5.5) with value type `T`. The type `X::iterator` is convertible to `X::const_iterator`.

`typename X::const_iterator`

7 *Result*: A type that meets the requirements of a constant iterator and those of a forward iterator with value type `T`.

`typename X::difference_type`

8 *Result*: A signed integer type, identical to the difference type of `X::iterator` and `X::const_iterator`.

`typename X::size_type`

9 *Result*: An unsigned integer type that can represent any non-negative value of `X::difference_type`.

```
X u;
X u = X();
```

10 *Postconditions*: `u.empty()`

11 *Complexity*: Constant.

```
X u(v);
X u = v;
```

12 *Preconditions*: `T` is *Cpp17CopyInsertable* into `X` (see below).

13 *Postconditions*: `u == v`.

14 *Complexity*: Linear.

```
X u(rv);
X u = rv;
```

15 *Postconditions*: `u` is equal to the value that `rv` had before this construction.

16 *Complexity*: Linear for `array` and `inplace_vector` and constant for all other standard containers.

`t = v`

17 *Result*: `X&`.

18 *Postconditions*: `t == v`.

19 *Complexity*: Linear.

`t = rv`

20 *Result*: `X&`.

21 *Effects*: All existing elements of `t` are either move assigned to or destroyed.

22 *Postconditions*: If `t` and `rv` do not refer to the same object, `t` is equal to the value that `rv` had before this assignment.

23 *Complexity*: Linear.

`a.~X()`

24 *Result*: `void`.

25 *Effects*: Destroys every element of `a`; any memory obtained is deallocated.

26 *Complexity*: Linear.

`b.begin()`

27 *Result*: `const_iterator` if `b` is of type `const X`; `iterator` otherwise.

28 *Returns*: An iterator referring to the first element in the container.

29 *Complexity*: Constant.

`b.end()`

30 *Result*: `const_iterator` if `b` is of type `const X`; `iterator` otherwise.

31 *Returns*: An iterator which is the past-the-end value for the container.

32 *Complexity*: Constant.

`b.cbegin()`

33 *Result*: `const_iterator`.

34 *Returns*: `const_cast<X const&>(b).begin()`

35 *Complexity*: Constant.

`b.cend()`

36 *Result*: `const_iterator`.

37 *Returns*: `const_cast<X const&>(b).end()`

38 *Complexity*: Constant.

`i <=> j`

39 *Result*: `strong_ordering`.

40 *Constraints*: `X::iterator` meets the random access iterator requirements.

41 *Complexity*: Constant.

`c == b`

42 *Preconditions*: `T` meets the *Cpp17EqualityComparable* requirements.

43 *Result*: `bool`.

44 *Returns*: `equal(c.begin(), c.end(), b.begin(), b.end())`

[*Note 1*: The algorithm `equal` is defined in 26.6.13. — *end note*]

45 *Complexity*: Constant if `c.size() != b.size()`, linear otherwise.

46 *Remarks*: `==` is an equivalence relation.

`c != b`

47 *Effects*: Equivalent to `!(c == b)`.

`t.swap(s)`

48 *Result*: `void`.

49 *Effects*: Exchanges the contents of `t` and `s`.

50 *Complexity*: Linear for `array` and `inplace_vector`, and constant for all other standard containers.

`swap(t, s)`

51 *Effects*: Equivalent to `t.swap(s)`.

`c.size()`

52 *Result*: `size_type`.

53 *Returns*: `distance(c.begin(), c.end())`, i.e., the number of elements in the container.

54 *Complexity*: Constant.

55 *Remarks*: The number of elements is defined by the rules of constructors, inserts, and erases.

`c.max_size()`

56 *Result*: `size_type`.

57 *Returns*: `distance(begin(), end())` for the largest possible container.

58 *Complexity*: Constant.

`c.empty()`

59 *Result*: `bool`.

60 *Returns*: `c.begin() == c.end()`

61 *Complexity*: Constant.

62 *Remarks*: If the container is empty, then `c.empty()` is `true`.

63 In the expressions

```
i == j
i != j
i < j
i <= j
i >= j
i > j
i <=> j
i - j
```

where `i` and `j` denote objects of a container's `iterator` type, either or both may be replaced by an object of the container's `const_iterator` type referring to the same element with no change in semantics.

64 Unless otherwise specified, all containers defined in this Clause obtain memory using an allocator (see 16.4.4.6).

[*Note 2*: In particular, containers and iterators do not store references to allocated elements other than through the allocator's pointer type, i.e., as objects of type `P` or `pointer_traits<P>::template rebind<`*`unspecified`*`>`, where `P` is `allocator_traits<allocator_type>::pointer`. — *end note*]

Copy constructors for these container types obtain an allocator by calling `allocator_traits<allocator_type>::select_on_container_copy_construction` on the allocator belonging to the container being copied. Move constructors obtain an allocator by move construction from the allocator belonging to the container being moved. Such move construction of the allocator shall not exit via an exception. All other constructors for these container types take a `const allocator_type&` argument.

[*Note 3*: If an invocation of a constructor uses the default value of an optional allocator argument, then the allocator type must support value-initialization. — *end note*]

A copy of this allocator is used for any memory allocation and element construction performed, by these constructors and by all other member functions, during the lifetime of each container object or until the allocator is replaced. The allocator may be replaced only via assignment or `swap()`. Allocator replacement is performed by copy assignment, move assignment, or swapping of the allocator only if

(64.1) — `allocator_traits<allocator_type>::propagate_on_container_copy_assignment::value`,

(64.2) — `allocator_traits<allocator_type>::propagate_on_container_move_assignment::value`, or

(64.3) — `allocator_traits<allocator_type>::propagate_on_container_swap::value`

is `true` within the implementation of the corresponding container operation. In all container types defined in this Clause, the member `get_allocator()` returns a copy of the allocator used to construct the container or, if that allocator has been replaced, a copy of the most recent replacement.

65 The expression `a.swap(b)`, for containers `a` and `b` of a standard container type other than `array` and `inplace_vector`, shall exchange the values of `a` and `b` without invoking any move, copy, or swap operations on the individual container elements. Any `Compare`, `Pred`, or `Hash` types belonging to `a` and `b` shall meet the *Cpp17Swappable* requirements and shall be exchanged by calling `swap` as described in 16.4.4.3. If `allocator_traits<allocator_type>::propagate_on_container_swap::value` is `true`, then `allocator_type` shall meet the *Cpp17Swappable* requirements and the allocators of `a` and `b` shall also be exchanged by calling `swap` as described in 16.4.4.3. Otherwise, the allocators shall not be swapped, and the behavior is undefined unless `a.get_allocator() == b.get_allocator()`. Every iterator referring to an element in one container before the swap shall refer to the same element in the other container after the swap. It is unspecified whether an iterator with value `a.end()` before the swap will have value `b.end()` after the swap.

66 Unless otherwise specified (see 23.2.7.2, 23.2.8.2, 23.3.5.4, 23.3.16.5, and 23.3.13.5) all container types defined in this Clause meet the following additional requirements:

(66.1) — If an exception is thrown by an `insert()` or `emplace()` function while inserting a single element, that function has no effects.

(66.2) — If an exception is thrown by a `push_back()`, `push_front()`, `emplace_back()`, or `emplace_front()` function, that function has no effects.

(66.3) — No `erase()`, `clear()`, `pop_back()` or `pop_front()` function throws an exception.

(66.4) — No copy constructor or assignment operator of a returned iterator throws an exception.

(66.5) — No `swap()` function throws an exception.

(66.6) — No `swap()` function invalidates any references, pointers, or iterators referring to the elements of the containers being swapped.

[*Note 4*: The `end()` iterator does not refer to any element, so it can be invalidated. — *end note*]

67 Unless otherwise specified (either explicitly or by defining a function in terms of other functions), invoking a container member function or passing a container as an argument to a library function shall not invalidate iterators to, or change the values of, objects within that container.

68 A *contiguous container* is a container whose member types `iterator` and `const_iterator` meet the *Cpp17RandomAccessIterator* requirements (24.3.5.7) and model `contiguous_iterator` (24.3.4.14).

69 The behavior of certain container member functions and deduction guides depends on whether types qualify as input iterators or allocators. The extent to which an implementation determines that a type cannot be an input iterator is unspecified, except that as a minimum integral types shall not qualify as input iterators. Likewise, the extent to which an implementation determines that a type cannot be an allocator is unspecified, except that as a minimum a type `A` shall not qualify as an allocator unless it meets both of the following conditions:

(69.1) — The *qualified-id* `A::value_type` is valid and denotes a type (13.10.3).

(69.2) — The expression `declval<A&>().allocate(size_t{})` is well-formed when treated as an unevaluated operand.

23.2.2.3 Reversible container requirements [container.rev.reqmts]

1 A type `X` meets the *reversible container* requirements if `X` meets the container requirements, the iterator type of `X` belongs to the bidirectional or random access iterator categories (24.3), and the following types and expressions are well-formed and have the specified semantics.

`typename X::reverse_iterator`

2 *Result*: The type `reverse_iterator<X::iterator>`, an iterator type whose value type is `T`.

`typename X::const_reverse_iterator`

3 *Result*: The type `reverse_iterator<X::const_iterator>`, a constant iterator type whose value type is `T`.

`a.rbegin()`

4 *Result*: `const_reverse_iterator` if `a` is of type `const X`; `reverse_iterator` otherwise.

5 *Returns*: `reverse_iterator(end())`

6 *Complexity*: Constant.

`a.rend()`

7 *Result*: `const_reverse_iterator` if `a` is of type `const X`; `reverse_iterator` otherwise.

8 *Returns*: `reverse_iterator(begin())`

9 *Complexity*: Constant.

`a.crbegin()`

10 *Result*: `const_reverse_iterator`.

11 *Returns*: `const_cast<X const&>(a).rbegin()`

12 *Complexity*: Constant.

`a.crend()`

13 *Result*: `const_reverse_iterator`.

14 *Returns*: `const_cast<X const&>(a).rend()`

15 *Complexity*: Constant.

23.2.2.4 Optional container requirements [container.opt.reqmts]

1 The following operations are provided for some types of containers but not others. Those containers for which the listed operations are provided shall implement the semantics as described unless otherwise stated. If the iterators passed to `lexicographical_compare_three_way` meet the constexpr iterator requirements (24.3.1) then the operations described below are implemented by constexpr functions.

`a <=> b`

2 *Result*: *`synth-three-way-result`*`<X::value_type>`.

3 *Preconditions*: Either `T` models `three_way_comparable`, or `<` is defined for values of type (possibly const) `T` and `<` is a total ordering relationship.

4 *Returns*: `lexicographical_compare_three_way(a.begin(), a.end(), b.begin(), b.end(),` *`synth-three-way`*`)`

[*Note 1*: The algorithm `lexicographical_compare_three_way` is defined in Clause 26. — *end note*]

5 *Complexity*: Linear.

23.2.2.5 Allocator-aware containers [container.alloc.reqmts]

1 Except for `array` and `inplace_vector`, all of the containers defined in Clause 23, 19.6.4, 27.4.3, and 28.6.9 meet the additional requirements of an *allocator-aware container*, as described below.

2 Given an allocator type `A` and given a container type `X` having a `value_type` identical to `T` and an `allocator_type` identical to `allocator_traits<A>::rebind_alloc<T>` and given an lvalue `m` of type `A`, a pointer `p` of type `T*`, an expression `v` that denotes an lvalue of type `T` or `const T` or an rvalue of type `const T`, and an rvalue `rv` of type `T`, the following terms are defined. If `X` is not allocator-aware or is a specialization of `basic_string`, the terms below are defined as if `A` were `allocator<T>` — no allocator object needs to be created and user specializations of `allocator<T>` are not instantiated:

(2.1) — `T` is *Cpp17DefaultInsertable into `X`* means that the following expression is well-formed:

`allocator_traits<A>::construct(m, p)`

(2.2) — An element of `X` is *default-inserted* if it is initialized by evaluation of the expression

`allocator_traits<A>::construct(m, p)`

where `p` is the address of the uninitialized storage for the element allocated within `X`.

(2.3) — `T` is *Cpp17MoveInsertable into `X`* means that the following expression is well-formed:

`allocator_traits<A>::construct(m, p, rv)`

and its evaluation causes the following postcondition to hold: The value of `*p` is equivalent to the value of `rv` before the evaluation.

[*Note 1*: `rv` remains a valid object. Its state is unspecified. — *end note*]

(2.4) — `T` is *Cpp17CopyInsertable into `X`* means that, in addition to `T` being *Cpp17MoveInsertable* into `X`, the following expression is well-formed:

```
allocator_traits<A>::construct(m, p, v)
```

and its evaluation causes the following postcondition to hold: The value of `v` is unchanged and is equivalent to `*p`.

(2.5) — `T` is *Cpp17EmplaceConstructible into `X` from `args`*, for zero or more arguments `args`, means that the following expression is well-formed:

```
allocator_traits<A>::construct(m, p, args)
```

(2.6) — `T` is *Cpp17Erasable from `X`* means that the following expression is well-formed:

```
allocator_traits<A>::destroy(m, p)
```

[*Note 2*: A container calls `allocator_traits<A>::construct(m, p, args)` to construct an element at `p` using `args`, with `m == get_allocator()`. The default `construct` in `allocator` will call `::new((void*)p) T(args)`, but specialized allocators can choose a different definition. — *end note*]

3 In this subclause,

(3.1) — `X` denotes an allocator-aware container class with a `value_type` of `T` using an allocator of type `A`,

(3.2) — `u` denotes a variable,

(3.3) — `a` and `b` denote non-const lvalues of type `X`,

(3.4) — `c` denotes an lvalue of type `const X`,

(3.5) — `t` denotes an lvalue or a const rvalue of type `X`,

(3.6) — `rv` denotes a non-const rvalue of type `X`, and

(3.7) — `m` is a value of type `A`.

A type `X` meets the allocator-aware container requirements if `X` meets the container requirements and the following types, statements, and expressions are well-formed and have the specified semantics.

`typename X::allocator_type`

4 *Result*: `A`

5 *Mandates*: `allocator_type::value_type` is the same as `X::value_type`.

`c.get_allocator()`

6 *Result*: `A`

7 *Complexity*: Constant.

```
X u;
X u = X();
```

8 *Preconditions*: `A` meets the *Cpp17DefaultConstructible* requirements.

9 *Postconditions*: `u.empty()` returns `true`, `u.get_allocator() == A()`.

10 *Complexity*: Constant.

`X u(m);`

11 *Postconditions*: `u.empty()` returns `true`, `u.get_allocator() == m`.

12 *Complexity*: Constant.

`X u(t, m);`

13 *Preconditions*: `T` is *Cpp17CopyInsertable* into `X`.

14 *Postconditions*: `u == t`, `u.get_allocator() == m`.

15 *Complexity*: Linear.

`X u(rv);`

16 *Postconditions*: `u` has the same elements as `rv` had before this construction; the value of `u.get_allocator()` is the same as the value of `rv.get_allocator()` before this construction.

17 *Complexity*: Constant.

`X u(rv, m);`

18 *Preconditions*: `T` is *Cpp17MoveInsertable* into `X`.

19 *Postconditions*: `u` has the same elements, or copies of the elements, that `rv` had before this construction, `u.get_allocator() == m`.

20 *Complexity*: Constant if `m == rv.get_allocator()`, otherwise linear.

`a = t`

21 *Result*: `X&`.

22 *Preconditions*: `T` is *Cpp17CopyInsertable* into `X` and *Cpp17CopyAssignable*.

23 *Postconditions*: `a == t` is `true`.

24 *Complexity*: Linear.

`a = rv`

25 *Result*: `X&`.

26 *Preconditions*: If `allocator_traits<allocator_type>::propagate_on_container_move_assignment::value` is `false`, `T` is *Cpp17MoveInsertable* into `X` and *Cpp17MoveAssignable*.

27 *Effects*: All existing elements of `a` are either move assigned to or destroyed.

28 *Postconditions*: If `a` and `rv` do not refer to the same object, `a` is equal to the value that `rv` had before this assignment.

29 *Complexity*: Linear.

`a.swap(b)`

30 *Result*: `void`

31 *Effects*: Exchanges the contents of `a` and `b`.

32 *Complexity*: Constant.

23.2.3 Container data races [container.requirements.dataraces]

1 For purposes of avoiding data races (16.4.6.10), implementations shall consider the following functions to be `const`: `begin`, `end`, `rbegin`, `rend`, `front`, `back`, `data`, `find`, `lower_bound`, `upper_bound`, `equal_range`, `at` and, except in associative or unordered associative containers, `operator[]`.

2 Notwithstanding 16.4.6.10, implementations are required to avoid data races when the contents of the contained object in different elements in the same container, excepting `vector<bool>`, are modified concurrently.

3 [*Note 1*: For a `vector<int> x` with a size greater than one, `x[1] = 5` and `*x.begin() = 10` can be executed concurrently without a data race, but `x[0] = 5` and `*x.begin() = 10` executed concurrently can result in a data race. As an exception to the general rule, for a `vector<bool> y`, `y[0] = true` can race with `y[1] = true`. — *end note*]

23.2.4 Sequence containers [sequence.reqmts]

1 A sequence container organizes a finite set of objects, all of the same type, into a strictly linear arrangement. The library provides the following basic kinds of sequence containers: `vector`, `inplace_vector`, `forward_list`, `list`, and `deque`. In addition, `array` and `hive` are provided as sequence containers which provide limited sequence operations, in `array`'s case because it has a fixed number of elements, and in `hive`'s case because insertion order is unspecified. The library also provides container adaptors that make it easy to construct abstract data types, such as `stacks`, `queues`, `flat_maps`, `flat_multimaps`, `flat_sets`, or `flat_multisets`, out of the basic sequence container kinds (or out of other program-defined sequence containers).

2 In this subclause,

(2.1) — `X` denotes a sequence container class,

(2.2) — `a` denotes a value of type `X` containing elements of type `T`,

(2.3) — `u` denotes the name of a variable being declared,

(2.4) — `A` denotes `X::allocator_type` if the *qualified-id* `X::allocator_type` is valid and denotes a type (13.10.3) and `allocator<T>` if it doesn't,

(2.5) — `i` and `j` denote iterators that meet the *Cpp17InputIterator* requirements and refer to elements implicitly convertible to `value_type`,

(2.6) — [`i`, `j`) denotes a valid range,

(2.7) — `rg` denotes a value of a type `R` that models *`container-compatible-range`*`<T>`,

(2.8) — `il` designates an object of type `initializer_list<value_type>`,

(2.9) — `n` denotes a value of type `X::size_type`,

(2.10) — `p` denotes a valid constant iterator to `a`,

(2.11) — `q` denotes a valid dereferenceable constant iterator to `a`,

(2.12) — [`q1`, `q2`) denotes a valid range of constant iterators in `a`,

(2.13) — `t` denotes an lvalue or a const rvalue of `X::value_type`, and

(2.14) — `rv` denotes a non-const rvalue of `X::value_type`.

(2.15) — `Args` denotes a template parameter pack;

(2.16) — `args` denotes a function parameter pack with the pattern `Args&&`.

3 The complexities of the expressions are sequence dependent.

4 A type `X` meets the *sequence container* requirements if `X` meets the container requirements and the following statements and expressions are well-formed and have the specified semantics.

`X u(n, t);`

5 *Preconditions*: `T` is *Cpp17CopyInsertable* into `X`.

6 *Effects*: Constructs a sequence container with `n` copies of `t`.

7 *Postconditions*: `distance(u.begin(), u.end()) == n` is `true`.

`X u(i, j);`

8 *Preconditions*: `T` is *Cpp17EmplaceConstructible* into `X` from `*i`. For `vector`, if the iterator does not meet the *Cpp17ForwardIterator* requirements (24.3.5.5), `T` is also *Cpp17MoveInsertable* into `X`.

9 *Effects*: Constructs a sequence container equal to the range [`i`, `j`). Each iterator in the range [`i`, `j`) is dereferenced exactly once.

10 *Postconditions*: `distance(u.begin(), u.end()) == distance(i, j)` is `true`.

`X(from_range, rg)`

11 *Preconditions*: `T` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`. For `vector`, if `R` models `ranges::approximately_sized_range` but not `ranges::sized_range` or models `ranges::input_range` but not `ranges::forward_range`, `T` is also *Cpp17MoveInsertable* into `X`.

12 *Effects*: Constructs a sequence container equal to the range `rg`. Each iterator in the range `rg` is dereferenced exactly once.

13 *Recommended practice*: If `R` models `ranges::approximately_sized_range` and `ranges::distance(rg) <= ranges::reserve_hint(rg)` is `true`, an implementation should not perform more than a single reallocation.

14 *Postconditions*: `distance(begin(), end()) == ranges::distance(rg)` is `true`.

`X(il)`

15 *Effects*: Equivalent to `X(il.begin(), il.end())`.

`a = il`

16 *Result*: `X&`.

17 *Preconditions*: `T` is *Cpp17CopyInsertable* into `X` and *Cpp17CopyAssignable*.

18 *Effects*: Assigns the range [`il.begin()`, `il.end()`) into `a`. All existing elements of `a` are either assigned to or destroyed.

19 *Returns*: `*this`.

`a.emplace(p, args)`

20 *Result*: `iterator`.

21 *Preconditions*: `T` is *Cpp17EmplaceConstructible* into `X` from `args`. For `vector`, `inplace_vector`, and `deque`, `T` is also *Cpp17MoveInsertable* into `X` and *Cpp17MoveAssignable*.

22 *Effects*: Inserts an object of type `T` constructed with `std::forward<Args>(args)...` before `p`.

[*Note 1*: `args` can directly or indirectly refer to a value in `a`. — *end note*]

23 *Returns*: An iterator that points to the new element.

`a.insert(p, t)`

24 *Result*: `iterator`.

25 *Preconditions*: `T` is *Cpp17CopyInsertable* into `X`. For `vector`, `inplace_vector`, and `deque`, `T` is also *Cpp17CopyAssignable*.

26 *Effects*: Inserts a copy of `t` before `p`.

27 *Returns*: An iterator that points to the copy of `t` inserted into `a`.

`a.insert(p, rv)`

28 *Result*: `iterator`.

29 *Preconditions*: `T` is *Cpp17MoveInsertable* into `X`. For `vector`, `inplace_vector`, and `deque`, `T` is also *Cpp17MoveAssignable*.

30 *Effects*: Inserts a copy of `rv` before `p`.

31 *Returns*: An iterator that points to the copy of `rv` inserted into `a`.

`a.insert(p, n, t)`

32 *Result*: `iterator`.

33 *Preconditions*: `T` is *Cpp17CopyInsertable* into `X` and *Cpp17CopyAssignable*.

34 *Effects*: Inserts `n` copies of `t` before `p`.

35 *Returns*: An iterator that points to the copy of the first element inserted into `a`, or `p` if `n == 0`.

`a.insert(p, i, j)`

36 *Result*: `iterator`.

37 *Preconditions*: `T` is *Cpp17EmplaceConstructible* into `X` from `*i`. For `vector`, `inplace_vector`, and `deque`, `T` is also *Cpp17MoveInsertable* into `X`, and `T` meets the *Cpp17MoveConstructible*, *Cpp17MoveAssignable*, and *Cpp17Swappable* (16.4.4.3) requirements. Neither `i` nor `j` are iterators into `a`.

38 *Effects*: Inserts copies of elements in [`i`, `j`) before `p`. Each iterator in the range [`i`, `j`) shall be dereferenced exactly once.

39 *Returns*: An iterator that points to the copy of the first element inserted into `a`, or `p` if `i == j`.

`a.insert_range(p, rg)`

40 *Result*: `iterator`.

41 *Preconditions*: `T` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`. For `vector`, `inplace_vector`, and `deque`, `T` is also *Cpp17MoveInsertable* into `X`, and `T` meets the *Cpp17MoveConstructible*, *Cpp17MoveAssignable*, and *Cpp17Swappable* (16.4.4.3) requirements. `rg` and `a` do not overlap.

42 *Effects*: Inserts copies of elements in `rg` before `p`. Each iterator in the range `rg` is dereferenced exactly once.

43 *Returns*: An iterator that points to the copy of the first element inserted into `a`, or `p` if `rg` is empty.

`a.insert(p, il)`

44 *Effects*: Equivalent to `a.insert(p, il.begin(), il.end())`.

`a.erase(q)`

45 *Result*: `iterator`.

46 *Preconditions*: For `vector`, `inplace_vector`, and `deque`, `T` is *Cpp17MoveAssignable*.

47 *Effects*: Erases the element pointed to by `q`.

48 *Returns*: An iterator that points to the element immediately following `q` prior to the element being erased. If no such element exists, `a.end()` is returned.

`a.erase(q1, q2)`

49 *Result*: `iterator`.

50 *Preconditions*: For `vector`, `inplace_vector`, and `deque`, `T` is *Cpp17MoveAssignable*.

51 *Effects*: Erases the elements in the range [`q1`, `q2`).

52 *Returns*: An iterator that points to the element pointed to by `q2` prior to any elements being erased. If no such element exists, `a.end()` is returned.

`a.clear()`

53 *Result*: `void`

54 *Effects*: Destroys all elements in `a`. Invalidates all references, pointers, and iterators referring to the elements of `a` and may invalidate the past-the-end iterator.

55 *Postconditions*: `a.empty()` is `true`.

56 *Complexity*: Linear.

`a.assign(i, j)`

57 *Result*: `void`

58 *Preconditions*: `T` is *Cpp17EmplaceConstructible* into `X` from `*i` and assignable from `*i`. For `vector`, if the iterator does not meet the forward iterator requirements (24.3.5.5), `T` is also *Cpp17MoveInsertable* into `X`. Neither `i` nor `j` are iterators into `a`.

59 *Effects*: Replaces elements in `a` with a copy of [`i`, `j`). Invalidates all references, pointers and iterators referring to the elements of `a`. For `vector` and `deque`, also invalidates the past-the-end iterator. Each iterator in the range [`i`, `j`) is dereferenced exactly once.

`a.assign_range(rg)`

60 *Result*: `void`

61 *Mandates*: `assignable_from<T&, ranges::range_reference_t<R>>` is modeled. For `inplace_vector`, if `ranges::size(rg)` is a constant expression, then `ranges::size(rg)` $\leq$ `a.max_size()`.

62 *Preconditions*: `T` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`. For `vector`, if `R` models `ranges::approximately_sized_range` but not `ranges::sized_range` or models `ranges::input_range` but not `ranges::forward_range`, `T` is also *Cpp17MoveInsertable* into `X`. `rg` and `a` do not overlap.

63 *Effects*: Replaces elements in `a` with a copy of each element in `rg`. Invalidates all references, pointers, and iterators referring to the elements of `a`. For `vector` and `deque`, also invalidates the past-the-end iterator. Each iterator in the range `rg` is dereferenced exactly once.

64 *Recommended practice*: If `R` models `ranges::approximately_sized_range` and `ranges::distance(rg) <= ranges::reserve_hint(rg)` is `true`, an implementation should not perform any reallocation.

`a.assign(il)`

65 *Effects*: Equivalent to `a.assign(il.begin(), il.end())`.

`a.assign(n, t)`

66 *Result*: `void`

67 *Preconditions*: `T` is *Cpp17CopyInsertable* into `X` and *Cpp17CopyAssignable*. `t` is not a reference into `a`.

68 *Effects*: Replaces elements in `a` with `n` copies of `t`. Invalidates all references, pointers and iterators referring to the elements of `a`. For `vector` and `deque`, also invalidates the past-the-end iterator.

69 For every sequence container defined in this Clause and in Clause 27:

(69.1) — If the constructor

```
template<class InputIterator>
  X(InputIterator first, InputIterator last,
    const allocator_type& alloc = allocator_type());
```

is called with a type `InputIterator` that does not qualify as an input iterator, then the constructor shall not participate in overload resolution.

(69.2) — If the member functions of the forms:

```
template<class InputIterator>
  return-type F(const_iterator p,
                InputIterator first, InputIterator last);       // such as insert

template<class InputIterator>
  return-type F(InputIterator first, InputIterator last);       // such as append, assign

template<class InputIterator>
  return-type F(const_iterator i1, const_iterator i2,
                InputIterator first, InputIterator last);       // such as replace
```

are called with a type `InputIterator` that does not qualify as an input iterator, then these functions shall not participate in overload resolution.

(69.3) — A deduction guide for a sequence container shall not participate in overload resolution if it has an `InputIterator` template parameter and a type that does not qualify as an input iterator is deduced for that parameter, or if it has an `Allocator` template parameter and a type that does not qualify as an allocator is deduced for that parameter.

70 The following operations are provided for some types of sequence containers but not others. Operations other than `prepend_range` and `append_range` are implemented so as to take amortized constant time.

`a.front()`

71 *Result*: `const_reference` if `a` is of type `const X`; `reference` otherwise.

72 *Hardened preconditions*: `a.empty()` is `false`.

73 *Returns*: `*a.begin()`

74 *Remarks*: Required for `basic_string`, `array`, `deque`, `forward_list`, `inplace_vector`, `list`, and `vector`.

`a.back()`

75 *Result*: `const_reference` if `a` is of type `const X`; `reference` otherwise.

76 *Hardened preconditions*: `a.empty()` is `false`.

77 *Effects*: Equivalent to:

```
auto tmp = a.end();
--tmp;
return *tmp;
```

78 *Remarks*: Required for `basic_string`, `array`, `deque`, `inplace_vector`, `list`, and `vector`.

`a.emplace_front(args)`

79 *Result*: `reference`

80 *Preconditions*: `T` is *Cpp17EmplaceConstructible* into `X` from `args`.

81 *Effects*: Prepends an object of type `T` constructed with `std::forward<Args>(args)...`.

82 *Returns*: `a.front()`.

83 *Remarks*: Required for `deque`, `forward_list`, and `list`.

`a.emplace_back(args)`

84 *Result*: `reference`

85 *Preconditions*: `T` is *Cpp17EmplaceConstructible* into `X` from `args`. For `vector`, `T` is also *Cpp17MoveInsertable* into `X`.

86 *Effects*: Appends an object of type `T` constructed with `std::forward<Args>(args)...`.

87 *Returns*: `a.back()`.

88 *Remarks*: Required for `deque`, `inplace_vector`, `list`, and `vector`.

`a.push_front(t)`

89 *Result*: `void`

90 *Preconditions*: `T` is *Cpp17CopyInsertable* into `X`.

91 *Effects*: Prepends a copy of `t`.

92 *Remarks*: Required for `deque`, `forward_list`, and `list`.

`a.push_front(rv)`

93 *Result*: `void`

94 *Preconditions*: `T` is *Cpp17MoveInsertable* into `X`.

95 *Effects*: Prepends a copy of `rv`.

96 *Remarks*: Required for `deque`, `forward_list`, and `list`.

`a.prepend_range(rg)`

97 *Result*: `void`

98 *Preconditions*: `T` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`. For `deque`, `T` is also *Cpp17MoveInsertable* into `X`, and `T` meets the *Cpp17MoveConstructible*, *Cpp17MoveAssignable*, and *Cpp17Swappable* (16.4.4.3) requirements.

99 *Effects*: Inserts copies of elements in `rg` before `begin()`. Each iterator in the range `rg` is dereferenced exactly once.

[*Note 2*: The order of elements in `rg` is not reversed. — *end note*]

100 *Remarks*: Required for `deque`, `forward_list`, and `list`.

`a.push_back(t)`

101 *Result*: `void`

102 *Preconditions*: `T` is *Cpp17CopyInsertable* into `X`.

103 *Effects*: Appends a copy of `t`.

104 *Remarks*: Required for `basic_string`, `deque`, `inplace_vector`, `list`, and `vector`.

`a.push_back(rv)`

105 *Result*: `void`

106 *Preconditions*: `T` is *Cpp17MoveInsertable* into `X`.

107 *Effects*: Appends a copy of `rv`.

108 *Remarks*: Required for `basic_string`, `deque`, `inplace_vector`, `list`, and `vector`.

`a.append_range(rg)`

109 *Result*: `void`

110 *Preconditions*: `T` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`. For `vector`, `T` is also *Cpp17MoveInsertable* into `X`.

111 *Effects*: Inserts copies of elements in `rg` before `end()`. Each iterator in the range `rg` is dereferenced exactly once.

112 *Remarks*: Required for `deque`, `inplace_vector`, `list`, and `vector`.

`a.pop_front()`

113 *Result*: `void`

114 *Hardened preconditions*: `a.empty()` is `false`.

115 *Effects*: Destroys the first element.

116 *Remarks*: Required for `deque`, `forward_list`, and `list`.

`a.pop_back()`

117 *Result*: `void`

118 *Hardened preconditions*: `a.empty()` is `false`.

119 *Effects*: Destroys the last element.

120 *Remarks*: Required for `basic_string`, `deque`, `inplace_vector`, `list`, and `vector`.

`a[n]`

121 *Result*: `const_reference` if `a` is of type `const X`; `reference` otherwise.

122 *Hardened preconditions*: `n < a.size()` is `true`.

123 *Effects*: Equivalent to: `return *(a.begin() + n);`

124 *Remarks*: Required for `basic_string`, `array`, `deque`, `inplace_vector`, and `vector`.

`a.at(n)`

125 *Result*: `const_reference` if `a` is of type `const X`; `reference` otherwise.

126 *Returns*: `*(a.begin() + n)`

127 *Throws*: `out_of_range` if `n >= a.size()`.

128 *Remarks*: Required for `basic_string`, `array`, `deque`, `inplace_vector`, and `vector`.

23.2.5 Node handles [container.node]

23.2.5.1 Overview [container.node.overview]

1 A *node handle* is an object that accepts ownership of a single element from an associative container (23.2.7) or an unordered associative container (23.2.8). It may be used to transfer that ownership to another container with compatible nodes. Containers with compatible nodes have the same node handle type. Elements may be transferred in either direction between container types in the same row of Table 75.

Table 75 — Container types with compatible nodes [tab:container.node.compat]

`map<K, T, C1, A>`	`map<K, T, C2, A>`
`map<K, T, C1, A>`	`multimap<K, T, C2, A>`
`set<K, C1, A>`	`set<K, C2, A>`
`set<K, C1, A>`	`multiset<K, C2, A>`
`unordered_map<K, T, H1, E1, A>`	`unordered_map<K, T, H2, E2, A>`
`unordered_map<K, T, H1, E1, A>`	`unordered_multimap<K, T, H2, E2, A>`
`unordered_set<K, H1, E1, A>`	`unordered_set<K, H2, E2, A>`
`unordered_set<K, H1, E1, A>`	`unordered_multiset<K, H2, E2, A>`

2 If a node handle is not empty, then it contains an allocator that is equal to the allocator of the container when the element was extracted. If a node handle is empty, it contains no allocator.

3 Class *`node-handle`* is for exposition only.

4 If a user-defined specialization of `pair` exists for `pair<const Key, T>` or `pair<Key, T>`, where `Key` is the container's `key_type` and `T` is the container's `mapped_type`, the behavior of operations involving node handles is undefined.

```
template<unspecified>
class node-handle {
public:
  // These type declarations are described in 23.2.7 and 23.2.8.
  using value_type      = see below;      // not present for map containers
  using key_type        = see below;      // not present for set containers
  using mapped_type     = see below;      // not present for set containers
```

```
  using allocator_type = see below;

private:
  using container-node-type = unspecified;                  // exposition only
  using ator-traits = allocator_traits<allocator_type>;     // exposition only

  typename ator-traits::template
    rebind_traits<container-node-type>::pointer ptr_;       // exposition only
  optional<allocator_type> alloc_;                          // exposition only

public:
  // 23.2.5.2, constructors, copy, and assignment
  constexpr node-handle() noexcept : ptr_(), alloc_() {}
  constexpr node-handle(node-handle&&) noexcept;
  constexpr node-handle& operator=(node-handle&&);

  // 23.2.5.3, destructor
  constexpr ~node-handle();

  // 23.2.5.4, observers
  constexpr value_type& value() const;          // not present for map containers
  key_type& key() const;                        // not present for set containers
  constexpr mapped_type& mapped() const;        // not present for set containers

  constexpr allocator_type get_allocator() const;
  constexpr explicit operator bool() const noexcept;
  constexpr bool empty() const noexcept;

  // 23.2.5.5, modifiers
  constexpr void swap(node-handle&)
    noexcept(ator-traits::propagate_on_container_swap::value ||
             ator-traits::is_always_equal::value);

  friend constexpr void swap(node-handle& x, node-handle& y) noexcept(noexcept(x.swap(y))) {
    x.swap(y);
  }
};
```

23.2.5.2 Constructors, copy, and assignment [container.node.cons]

`constexpr node-handle(node-handle&& nh) noexcept;`

1 *Effects*: Constructs a *node-handle* object initializing *ptr_* with `nh.ptr_`. Move constructs *alloc_* with `nh.alloc_`. Assigns `nullptr` to `nh.ptr_` and assigns `nullopt` to `nh.alloc_`.

`constexpr node-handle& operator=(node-handle&& nh);`

2 *Preconditions*: Either `!alloc_` is `true`, or *ator-traits*`::propagate_on_container_move_assignment::value` is `true`, or *alloc_* `==` `nh.alloc_` is `true`.

3 *Effects*:

(3.1) — If *ptr_* `!=` `nullptr` is `true`, destroys the `value_type` subobject in the *container-node-type* object pointed to by *ptr_* by calling *ator-traits*`::destroy`, then deallocates *ptr_* by calling *ator-traits*`::template rebind_traits<`*container-node-type*`>::deallocate`.

(3.2) — Assigns `nh.ptr_` to *ptr_*.

(3.3) — If `!`*alloc_* is `true` or *ator-traits*`::propagate_on_container_move_assignment::value` is `true`,
move assigns `nh.alloc_` to *alloc_*.

(3.4) — Assigns `nullptr` to `nh.ptr_` and assigns `nullopt` to `nh.alloc_`.

4 *Returns*: `*this`.

5 *Throws*: Nothing.

23.2.5.3 Destructor [container.node.dtor]

```
constexpr ~node-handle();
```

1 *Effects*: If *ptr_* `!= nullptr` is `true`, destroys the `value_type` subobject in the *container-node-type* object pointed to by *ptr_* by calling *ator-traits*`::destroy`, then deallocates *ptr_* by calling *ator-traits*`::template rebind_traits<`*container-node-type*`>::deallocate`.

23.2.5.4 Observers [container.node.observers]

```
constexpr value_type& value() const;
```

1 *Preconditions*: `empty() == false`.

2 *Returns*: A reference to the `value_type` subobject in the *container-node-type* object pointed to by *ptr_*.

3 *Throws*: Nothing.

```
key_type& key() const;
```

4 *Preconditions*: `empty() == false`.

5 *Returns*: A non-const reference to the `key_type` member of the `value_type` subobject in the *container-node-type* object pointed to by *ptr_*.

6 *Throws*: Nothing.

7 *Remarks*: Modifying the key through the returned reference is permitted.

```
constexpr mapped_type& mapped() const;
```

8 *Preconditions*: `empty() == false`.

9 *Returns*: A reference to the `mapped_type` member of the `value_type` subobject in the *container-node-type* object pointed to by *ptr_*.

10 *Throws*: Nothing.

```
constexpr allocator_type get_allocator() const;
```

11 *Preconditions*: `empty() == false`.

12 *Returns*: `*`*alloc_*.

13 *Throws*: Nothing.

```
constexpr explicit operator bool() const noexcept;
```

14 *Returns*: *ptr_* `!= nullptr`.

```
constexpr bool empty() const noexcept;
```

15 *Returns*: *ptr_* `== nullptr`.

23.2.5.5 Modifiers [container.node.modifiers]

```
constexpr void swap(node-handle& nh)
  noexcept(ator-traits::propagate_on_container_swap::value ||
           ator-traits::is_always_equal::value);
```

1 *Preconditions*: `!`*alloc_* is `true`, or `!nh.`*alloc_*, or *ator-traits*`::propagate_on_container_swap::value` is `true`, or *alloc_* `== nh.`*alloc_* is `true`.

2 *Effects*: Calls `swap(`*ptr_*`, nh.`*ptr_*`)`. If `!`*alloc_* is `true`, or `!nh.`*alloc_* is `true`, or *ator-traits*`::propagate_on_container_swap::value` is `true` calls `swap(`*alloc_*`, nh.`*alloc_*`)`.

23.2.6 Insert return type [container.insert.return]

1 The associative containers with unique keys and the unordered containers with unique keys have a member function `insert` that returns a nested type `insert_return_type`. That return type is a specialization of the template specified in this subclause.

```
template<class Iterator, class NodeType>
struct insert-return-type
{
  Iterator position;
  bool     inserted;
  NodeType node;
};
```

2 The name *insert-return-type* is for exposition only. *insert-return-type* has the template parameters, data members, and special members specified above. It has no base classes or members other than those specified.

23.2.7 Associative containers [associative.reqmts]

23.2.7.1 General [associative.reqmts.general]

1 Associative containers provide fast retrieval of data based on keys. The library provides four basic kinds of associative containers: `set`, `multiset`, `map` and `multimap`. The library also provides container adaptors that make it easy to construct abstract data types, such as `flat_maps`, `flat_multimaps`, `flat_sets`, or `flat_multisets`, out of the basic sequence container kinds (or out of other program-defined sequence containers).

2 Each associative container is parameterized on `Key` and an ordering relation `Compare` that induces a strict weak ordering (26.8) on elements of `Key`. In addition, `map` and `multimap` associate an arbitrary *mapped type* `T` with the `Key`. The object of type `Compare` is called the *comparison object* of a container.

3 The phrase "equivalence of keys" means the equivalence relation imposed by the comparison object. That is, two keys `k1` and `k2` are considered to be equivalent if for the comparison object `comp`, `comp(k1, k2) == false && comp(k2, k1) == false`.

[*Note 1*: This is not necessarily the same as the result of `k1 == k2`. — *end note*]

For any two keys `k1` and `k2` in the same container, calling `comp(k1, k2)` shall always return the same value.

4 An associative container supports *unique keys* if it may contain at most one element for each key. Otherwise, it supports *equivalent keys*. The `set` and `map` classes support unique keys; the `multiset` and `multimap` classes support equivalent keys. For `multiset` and `multimap`, `insert`, `emplace`, and `erase` preserve the relative ordering of equivalent elements.

5 For `set` and `multiset` the value type is the same as the key type. For `map` and `multimap` it is equal to `pair<const Key, T>`.

6 `iterator` of an associative container is of the bidirectional iterator category. For associative containers where the value type is the same as the key type, both `iterator` and `const_iterator` are constant iterators. It is unspecified whether or not `iterator` and `const_iterator` are the same type.

[*Note 2*: `iterator` and `const_iterator` have identical semantics in this case, and `iterator` is convertible to `const_iterator`. Users can avoid violating the one-definition rule by always using `const_iterator` in their function parameter lists. — *end note*]

7 In this subclause,

(7.1) — `X` denotes an associative container class,

(7.2) — `a` denotes a value of type `X`,

(7.3) — `a2` denotes a value of a type with nodes compatible with type `X` (Table 75),

(7.4) — `b` denotes a value of type `X` or `const X`,

(7.5) — `u` denotes the name of a variable being declared,

(7.6) — `a_uniq` denotes a value of type `X` when `X` supports unique keys,

(7.7) — `a_eq` denotes a value of type `X` when `X` supports equivalent keys,

(7.8) — `a_tran` denotes a value of type `X` or `const X` when the *qualified-id* `X::key_compare::is_transparent` is valid and denotes a type (13.10.3),

(7.9) — `i` and `j` meet the *Cpp17InputIterator* requirements and refer to elements implicitly convertible to `value_type`,

(7.10) — [`i`, `j`) denotes a valid range,

(7.11) — `rg` denotes a value of a type `R` that models *`container-compatible-range`*`<value_type>`,

(7.12) — `p` denotes a valid constant iterator to `a`,

(7.13) — `q` denotes a valid dereferenceable constant iterator to `a`,

(7.14) — `r` denotes a valid dereferenceable iterator to `a`,

(7.15) — [`q1`, `q2`) denotes a valid range of constant iterators in `a`,

(7.16) — `il` designates an object of type `initializer_list<value_type>`,

(7.17) — `t` denotes a value of type `X::value_type`,

(7.18) — `k` denotes a value of type `X::key_type`, and

(7.19) — `c` denotes a value of type `X::key_compare` or `const X::key_compare`;

(7.20) — `kl` is a value such that `a` is partitioned (26.8) with respect to `c(x, kl)`, with `x` the key value of `e` and `e` in `a`;

(7.21) — `ku` is a value such that `a` is partitioned with respect to `!c(ku, x)`, with `x` the key value of `e` and `e` in `a`;

(7.22) — `ke` is a value such that `a` is partitioned with respect to `c(x, ke)` and `!c(ke, x)`, with `c(x, ke)` implying `!c(ke, x)` and with `x` the key value of `e` and `e` in `a`;

(7.23) — `kx` is a value such that

(7.23.1) — `a` is partitioned with respect to `c(x, kx)` and `!c(kx, x)`, with `c(x, kx)` implying `!c(kx, x)` and with `x` the key value of `e` and `e` in `a`, and

(7.23.2) — `kx` is not convertible to either `iterator` or `const_iterator`; and

(7.24) — `A` denotes the storage allocator used by `X`, if any, or `allocator<X::value_type>` otherwise,

(7.25) — `m` denotes an allocator of a type convertible to `A`, and `nh` denotes a non-const rvalue of type `X::node_type`.

8 A type `X` meets the *associative container* requirements if `X` meets all the requirements of an allocator-aware container (23.2.2.5) and the following types, statements, and expressions are well-formed and have the specified semantics, except that for `map` and `multimap`, the requirements placed on `value_type` in 23.2.2.2 apply instead to `key_type` and `mapped_type`.

[*Note 3*: For example, in some cases `key_type` and `mapped_type` need to be *Cpp17CopyAssignable* even though the associated `value_type`, `pair<const key_type, mapped_type>`, is not *Cpp17CopyAssignable*. — *end note*]

`typename X::key_type`

9 *Result*: `Key`.

`typename X::mapped_type`

10 *Result*: `T`.

11 *Remarks*: For `map` and `multimap` only.

`typename X::value_type`

12 *Result*: `Key` for `set` and `multiset` only; `pair<const Key, T>` for `map` and `multimap` only.

13 *Preconditions*: `X::value_type` is *Cpp17Erasable* from `X`.

`typename X::key_compare`

14 *Result*: `Compare`.

15 *Preconditions*: `key_compare` is *Cpp17CopyConstructible*.

`typename X::value_compare`

16 *Result*: A binary predicate type. It is the same as `key_compare` for `set` and `multiset`; is an ordering relation on pairs induced by the first component (i.e., `Key`) for `map` and `multimap`.

`typename X::node_type`

17 *Result*: A specialization of the *`node-handle`* class template (23.2.5), such that the public nested types are the same types as the corresponding types in `X`.

`X(c)`

18 *Effects*: Constructs an empty container. Uses a copy of `c` as a comparison object.

19 *Complexity*: Constant.

```
X u = X();
X u;
```

20 *Preconditions*: `key_compare` meets the *Cpp17DefaultConstructible* requirements.

21 *Effects*: Constructs an empty container. Uses `Compare()` as a comparison object.

22 *Complexity*: Constant.

`X(i, j, c)`

23 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `X` from `*i`.

24 *Effects*: Constructs an empty container and inserts elements from the range [`i`, `j`) into it; uses `c` as a comparison object.

25 *Complexity*: $N \log N$ in general, where N has the value `distance(i, j)`; linear if [`i`, `j`) is sorted with respect to `value_comp()`.

`X(i, j)`

26 *Preconditions*: `key_compare` meets the *Cpp17DefaultConstructible* requirements. `value_type` is *Cpp17EmplaceConstructible* into `X` from `*i`.

27 *Effects*: Constructs an empty container and inserts elements from the range [`i`, `j`) into it; uses `Compare()` as a comparison object.

28 *Complexity*: $N \log N$ in general, where N has the value `distance(i, j)`; linear if [`i`, `j`) is sorted with respect to `value_comp()`.

`X(from_range, rg, c)`

29 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`.

30 *Effects*: Constructs an empty container and inserts each element from `rg` into it. Uses `c` as the comparison object.

31 *Complexity*: $N \log N$ in general, where N has the value `ranges::distance(rg)`; linear if `rg` is sorted with respect to `value_comp()`.

`X(from_range, rg)`

32 *Preconditions*: `key_compare` meets the *Cpp17DefaultConstructible* requirements. `value_type` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`.

33 *Effects*: Constructs an empty container and inserts each element from `rg` into it. Uses `Compare()` as the comparison object.

34 *Complexity*: Same as `X(from_range, rg, c)`.

`X(il, c)`

35 *Effects*: Equivalent to `X(il.begin(), il.end(), c)`.

`X(il)`

36 *Effects*: Equivalent to `X(il.begin(), il.end())`.

`a = il`

37 *Result*: `X&`

38 *Preconditions*: `value_type` is *Cpp17CopyInsertable* into `X` and *Cpp17CopyAssignable*.

39 *Effects*: Assigns the range [`il.begin()`, `il.end()`) into `a`. All existing elements of `a` are either assigned to or destroyed.

40 *Complexity*: $N \log N$ in general, where N has the value `il.size() + a.size()`; linear if [`il.begin()`, `il.end()`) is sorted with respect to `value_comp()`.

`b.key_comp()`

41 *Result*: `X::key_compare`

42 *Returns*: The comparison object out of which `b` was constructed.

43 *Complexity*: Constant.

`b.value_comp()`

44 *Result*: `X::value_compare`

45 *Returns*: An object of `value_compare` constructed out of the comparison object.

46 *Complexity*: Constant.

`a_uniq.emplace(args)`

47 *Result*: `pair<iterator, bool>`

48 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `X` from `args`.

49 *Effects*: Inserts a `value_type` object `t` constructed with `std::forward<Args>(args)...` if and only if there is no element in the container with key equivalent to the key of `t`.

50 *Returns*: The `bool` component of the returned pair is `true` if and only if the insertion takes place, and the iterator component of the pair points to the element with key equivalent to the key of `t`.

51 *Complexity*: Logarithmic.

`a_eq.emplace(args)`

52 *Result*: `iterator`

53 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `X` from `args`.

54 *Effects*: Inserts a `value_type` object `t` constructed with `std::forward<Args>(args)...`. If a range containing elements equivalent to `t` exists in `a_eq`, `t` is inserted at the end of that range.

55 *Returns*: An iterator pointing to the newly inserted element.

56 *Complexity*: Logarithmic.

`a.emplace_hint(p, args)`

57 *Result*: `iterator`

58 *Effects*: Equivalent to `a.emplace(std::forward<Args>(args)...)`, except that the element is inserted as close as possible to the position just prior to `p`.

59 *Returns*: The iterator returned by `emplace`.

60 *Complexity*: Logarithmic in general, but amortized constant if the element is inserted right before `p`.

`a_uniq.insert(t)`

61 *Result*: `pair<iterator, bool>`

62 *Preconditions*: If `t` is a non-const rvalue, `value_type` is *Cpp17MoveInsertable* into `X`; otherwise, `value_type` is *Cpp17CopyInsertable* into `X`.

63 *Effects*: Inserts `t` if and only if there is no element in the container with key equivalent to the key of `t`.

64 *Returns*: The `bool` component of the returned pair is `true` if and only if the insertion takes place, and the `iterator` component of the pair points to the element with key equivalent to the key of `t`.

65 *Complexity*: Logarithmic.

`a_eq.insert(t)`

66 *Result*: `iterator`

67 *Preconditions*: If `t` is a non-const rvalue, `value_type` is *Cpp17MoveInsertable* into `X`; otherwise, `value_type` is *Cpp17CopyInsertable* into `X`.

68 *Effects*: Inserts `t` and returns the iterator pointing to the newly inserted element. If a range containing elements equivalent to `t` exists in `a_eq`, `t` is inserted at the end of that range.

69 *Complexity*: Logarithmic.

`a.insert(p, t)`

70 *Result*: `iterator`

71 *Preconditions*: If `t` is a non-const rvalue, `value_type` is *Cpp17MoveInsertable* into `X`; otherwise, `value_type` is *Cpp17CopyInsertable* into `X`.

72 *Effects*: Inserts `t` if and only if there is no element with key equivalent to the key of `t` in containers with unique keys; always inserts `t` in containers with equivalent keys. `t` is inserted as close as possible to the position just prior to `p`.

73 *Returns*: An iterator pointing to the element with key equivalent to the key of `t`.

74 *Complexity*: Logarithmic in general, but amortized constant if `t` is inserted right before `p`.

`a.insert(i, j)`

75 *Result*: `void`

76 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `X` from `*i`. Neither `i` nor `j` are iterators into `a`.

77 *Effects*: Inserts each element from the range `[i, j)` if and only if there is no element with key equivalent to the key of that element in containers with unique keys; always inserts that element in containers with equivalent keys.

78 *Complexity*: $N \log(\texttt{a.size()} + N)$, where N has the value `distance(i, j)`.

`a.insert_range(rg)`

79 *Result*: `void`

80 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`. `rg` and `a` do not overlap.

81 *Effects*: Inserts each element from `rg` if and only if there is no element with key equivalent to the key of that element in containers with unique keys; always inserts that element in containers with equivalent keys.

82 *Complexity*: $N \log(\texttt{a.size()} + N)$, where N has the value `ranges::distance(rg)`.

`a.insert(il)`

83 *Effects*: Equivalent to `a.insert(il.begin(), il.end())`.

`a_uniq.insert(nh)`

84 *Result*: `insert_return_type`

85 *Preconditions*: `nh` is empty or `a_uniq.get_allocator() == nh.get_allocator()` is `true`.

86 *Effects*: If `nh` is empty, has no effect. Otherwise, inserts the element owned by `nh` if and only if there is no element in the container with a key equivalent to `nh.key()`.

87 *Returns*: If `nh` is empty, `inserted` is `false`, `position` is `end()`, and `node` is empty. Otherwise if the insertion took place, `inserted` is `true`, `position` points to the inserted element, and `node` is empty; if the insertion failed, `inserted` is `false`, `node` has the previous value of `nh`, and `position` points to an element with a key equivalent to `nh.key()`.

88 *Complexity*: Logarithmic.

`a_eq.insert(nh)`

89 *Result*: `iterator`

90 *Preconditions*: `nh` is empty or `a_eq.get_allocator() == nh.get_allocator()` is `true`.

91 *Effects*: If `nh` is empty, has no effect and returns `a_eq.end()`. Otherwise, inserts the element owned by `nh` and returns an iterator pointing to the newly inserted element. If a range containing elements with keys equivalent to `nh.key()` exists in `a_eq`, the element is inserted at the end of that range.

92 *Postconditions*: `nh` is empty.

93 *Complexity*: Logarithmic.

`a.insert(p, nh)`

94 *Result*: `iterator`

95 *Preconditions*: `nh` is empty or `a.get_allocator() == nh.get_allocator()` is `true`.

96 *Effects*: If `nh` is empty, has no effect and returns `a.end()`. Otherwise, inserts the element owned by `nh` if and only if there is no element with key equivalent to `nh.key()` in containers with unique keys; always inserts the element owned by `nh` in containers with equivalent keys. The element is inserted as close as possible to the position just prior to `p`.

97 *Postconditions*: `nh` is empty if insertion succeeds, unchanged if insertion fails.

98 *Returns*: An iterator pointing to the element with key equivalent to `nh.key()`.

99 *Complexity*: Logarithmic in general, but amortized constant if the element is inserted right before `p`.

`a.extract(k)`

100 *Result*: `node_type`

101 *Effects*: Removes the first element in the container with key equivalent to `k`.

102 *Returns*: A `node_type` owning the element if found, otherwise an empty `node_type`.

103 *Complexity*: log(`a.size()`)

`a_tran.extract(kx)`

104 *Result*: `node_type`

105 *Effects*: Removes the first element in the container with key `r` such that `!c(r, kx) && !c(kx, r)` is `true`.

106 *Returns*: A `node_type` owning the element if found, otherwise an empty `node_type`.

107 *Complexity*: log(`a_tran.size()`)

`a.extract(q)`

108 *Result*: `node_type`

109 *Effects*: Removes the element pointed to by `q`.

110 *Returns*: A `node_type` owning that element.

111 *Complexity*: Amortized constant.

`a.merge(a2)`

112 *Result*: `void`

113 *Preconditions*: `a.get_allocator() == a2.get_allocator()` is `true`.

114 *Effects*: Attempts to extract each element in `a2` and insert it into `a` using the comparison object of `a`. In containers with unique keys, if there is an element in `a` with key equivalent to the key of an element from `a2`, then that element is not extracted from `a2`.

115 *Postconditions*: Pointers and references to the transferred elements of `a2` refer to those same elements but as members of `a`. If `a.begin()` and `a2.begin()` have the same type, iterators referring to the transferred elements will continue to refer to their elements, but they now behave as iterators into `a`, not into `a2`.

116 *Throws*: Nothing unless the comparison object throws.

117 *Complexity*: $N \log(\texttt{a.size()}+N)$, where N has the value `a2.size()`.

`a.erase(k)`

118 *Result*: `size_type`

119 *Effects*: Erases all elements in the container with key equivalent to `k`.

120 *Returns*: The number of erased elements.

121 *Complexity*: log(`a.size()`) + `a.count(k)`

`a_tran.erase(kx)`

122 *Result*: `size_type`

123 *Effects*: Erases all elements in the container with key `r` such that `!c(r, kx) && !c(kx, r)` is `true`.

124 *Returns*: The number of erased elements.

125 *Complexity*: $\log($`a_tran.size()`$) +$ `a_tran.count(kx)`

`a.erase(q)`

126 *Result*: `iterator`

127 *Effects*: Erases the element pointed to by `q`.

128 *Returns*: An iterator pointing to the element immediately following `q` prior to the element being erased. If no such element exists, returns `a.end()`.

129 *Complexity*: Amortized constant.

`a.erase(r)`

130 *Result*: `iterator`

131 *Effects*: Erases the element pointed to by `r`.

132 *Returns*: An iterator pointing to the element immediately following `r` prior to the element being erased. If no such element exists, returns `a.end()`.

133 *Complexity*: Amortized constant.

`a.erase(q1, q2)`

134 *Result*: `iterator`

135 *Effects*: Erases all the elements in the range $[$`q1`$,$ `q2`$)$.

136 *Returns*: An iterator pointing to the element pointed to by `q2` prior to any elements being erased. If no such element exists, `a.end()` is returned.

137 *Complexity*: $\log($`a.size()`$) + N$, where N has the value `distance(q1, q2)`.

`a.clear()`

138 *Effects*: Equivalent to `a.erase(a.begin(), a.end())`.

139 *Postconditions*: `a.empty()` is `true`.

140 *Complexity*: Linear in `a.size()`.

`b.find(k)`

141 *Result*: `const_iterator` if `b` is of type `const X`; `iterator` otherwise.

142 *Returns*: An iterator pointing to an element with the key equivalent to `k`, or `b.end()` if such an element is not found.

143 *Complexity*: Logarithmic.

`a_tran.find(ke)`

144 *Result*: `const_iterator` if `a_tran` is of type `const X`; `iterator` otherwise.

145 *Returns*: An iterator pointing to an element with key `r` such that `!c(r, ke) && !c(ke, r)` is `true`, or `a_tran.end()` if such an element is not found.

146 *Complexity*: Logarithmic.

`b.count(k)`

147 *Result*: `size_type`

148 *Returns*: The number of elements with key equivalent to `k`.

149 *Complexity*: $\log($`b.size()`$) +$ `b.count(k)`

`a_tran.count(ke)`

150 *Result*: `size_type`

151 *Returns*: The number of elements with key `r` such that `!c(r, ke) && !c(ke, r)`.

152 *Complexity*: $\log(\texttt{a\_tran.size()}) + \texttt{a\_tran.count(ke)}$

`b.contains(k)`

153 *Result*: `bool`

154 *Effects*: Equivalent to: `return b.find(k) != b.end();`

`a_tran.contains(ke)`

155 *Result*: `bool`

156 *Effects*: Equivalent to: `return a_tran.find(ke) != a_tran.end();`

`b.lower_bound(k)`

157 *Result*: `const_iterator` if `b` is of type `const X`; `iterator` otherwise.

158 *Returns*: An iterator pointing to the first element with key not less than `k`, or `b.end()` if such an element is not found.

159 *Complexity*: Logarithmic.

`a_tran.lower_bound(kl)`

160 *Result*: `const_iterator` if `a_tran` is of type `const X`; `iterator` otherwise.

161 *Returns*: An iterator pointing to the first element with key `r` such that `!c(r, kl)`, or `a_tran.end()` if such an element is not found.

162 *Complexity*: Logarithmic.

`b.upper_bound(k)`

163 *Result*: `const_iterator` if `b` is of type `const X`; `iterator` otherwise.

164 *Returns*: An iterator pointing to the first element with key greater than `k`, or `b.end()` if such an element is not found.

165 *Complexity*: Logarithmic.

`a_tran.upper_bound(ku)`

166 *Result*: `const_iterator` if `a_tran` is of type `const X`; `iterator` otherwise.

167 *Returns*: An iterator pointing to the first element with key `r` such that `c(ku, r)`, or `a_tran.end()` if such an element is not found.

168 *Complexity*: Logarithmic.

`b.equal_range(k)`

169 *Result*: `pair<const_iterator, const_iterator>` if `b` is of type `const X`; `pair<iterator, iterator>` otherwise.

170 *Effects*: Equivalent to: `return make_pair(b.lower_bound(k), b.upper_bound(k));`

171 *Complexity*: Logarithmic.

`a_tran.equal_range(ke)`

172 *Result*: `pair<const_iterator, const_iterator>` if `a_tran` is of type `const X`; `pair<iterator, iterator>` otherwise.

173 *Effects*: Equivalent to: `return make_pair(a_tran.lower_bound(ke), a_tran.upper_bound(ke));`

174 *Complexity*: Logarithmic.

175 The `insert`, `insert_range`, and `emplace` members shall not affect the validity of iterators and references to the container, and the `erase` members shall invalidate only iterators and references to the erased elements.

176 The `extract` members invalidate only iterators to the removed element; pointers and references to the removed element remain valid. However, accessing the element through such pointers and references while the element is owned by a `node_type` is undefined behavior. References and pointers to an element obtained while it is owned by a `node_type` are invalidated if the element is successfully inserted.

177 The fundamental property of iterators of associative containers is that they iterate through the containers in the non-descending order of keys where non-descending is defined by the comparison that was used to construct them. For any two dereferenceable iterators `i` and `j` such that distance from `i` to `j` is positive, the following condition holds:

```
value_comp(*j, *i) == false
```

178 For associative containers with unique keys the stronger condition holds:

```
value_comp(*i, *j) != false
```

179 When an associative container is constructed by passing a comparison object the container shall not store a pointer or reference to the passed object, even if that object is passed by reference. When an associative container is copied, through either a copy constructor or an assignment operator, the target container shall then use the comparison object from the container being copied, as if that comparison object had been passed to the target container in its constructor.

180 The member function templates `find`, `count`, `contains`, `lower_bound`, `upper_bound`, `equal_range`, `erase`, and `extract` shall not participate in overload resolution unless the *qualified-id* `Compare::is_transparent` is valid and denotes a type (13.10.3). Additionally, the member function templates `extract` and `erase` shall not participate in overload resolution if `is_convertible_v<K&&, iterator> || is_convertible_v<K&&, const_iterator>` is `true`, where `K` is the type substituted as the first template argument.

181 A deduction guide for an associative container shall not participate in overload resolution if any of the following are true:

(181.1) — It has an `InputIterator` template parameter and a type that does not qualify as an input iterator is deduced for that parameter.

(181.2) — It has an `Allocator` template parameter and a type that does not qualify as an allocator is deduced for that parameter.

(181.3) — It has a `Compare` template parameter and a type that qualifies as an allocator is deduced for that parameter.

23.2.7.2 Exception safety guarantees [associative.reqmts.except]

1 For associative containers, no `clear()` function throws an exception. `erase(k)` does not throw an exception unless that exception is thrown by the container's `Compare` object (if any).

2 For associative containers, if an exception is thrown by any operation from within an `insert` or `emplace` function inserting a single element, the insertion has no effect.

3 For associative containers, no `swap` function throws an exception unless that exception is thrown by the swap of the container's `Compare` object (if any).

23.2.8 Unordered associative containers [unord.req]

23.2.8.1 General [unord.req.general]

1 Unordered associative containers provide an ability for fast retrieval of data based on keys. The worst-case complexity for most operations is linear, but the average case is much faster. The library provides four unordered associative containers: `unordered_set`, `unordered_map`, `unordered_multiset`, and `unordered_multimap`.

2 Unordered associative containers conform to the requirements for Containers (23.2), except that the expressions `a == b` and `a != b` have different semantics than for the other container types.

3 Each unordered associative container is parameterized by `Key`, by a function object type `Hash` that meets the *Cpp17Hash* requirements (16.4.4.5) and acts as a hash function for argument values of type `Key`, and by a binary predicate `Pred` that induces an equivalence relation on values of type `Key`. Additionally, `unordered_map` and `unordered_multimap` associate an arbitrary *mapped type* `T` with the `Key`.

4 The container's object of type `Hash` — denoted by `hash` — is called the *hash function* of the container. The container's object of type `Pred` — denoted by `pred` — is called the *key equality predicate* of the container.

5 Two values `k1` and `k2` are considered equivalent if the container's key equality predicate `pred(k1, k2)` is valid and returns `true` when passed those values. If `k1` and `k2` are equivalent, the container's hash function shall return the same value for both.

[*Note 1*: Thus, when an unordered associative container is instantiated with a non-default `Pred` parameter it usually needs a non-default `Hash` parameter as well. — *end note*]

For any two keys `k1` and `k2` in the same container, calling `pred(k1, k2)` shall always return the same value. For any key `k` in a container, calling `hash(k)` shall always return the same value.

6 An unordered associative container supports *unique keys* if it may contain at most one element for each key. Otherwise, it supports *equivalent keys*. `unordered_set` and `unordered_map` support unique keys. `unordered_multiset` and `unordered_multimap` support equivalent keys. In containers that support equivalent keys, elements with equivalent keys are adjacent to each other in the iteration order of the container. Thus, although the absolute order of elements in an unordered container is not specified, its elements are grouped into *equivalent-key groups* such that all elements of each group have equivalent keys. Mutating operations on unordered containers shall preserve the relative order of elements within each equivalent-key group unless otherwise specified.

7 For `unordered_set` and `unordered_multiset` the value type is the same as the key type. For `unordered_map` and `unordered_multimap` it is `pair<const Key, T>`.

8 For unordered containers where the value type is the same as the key type, both `iterator` and `const_iterator` are constant iterators. It is unspecified whether or not `iterator` and `const_iterator` are the same type.

[*Note 2*: `iterator` and `const_iterator` have identical semantics in this case, and `iterator` is convertible to `const_iterator`. Users can avoid violating the one-definition rule by always using `const_iterator` in their function parameter lists. — *end note*]

9 The elements of an unordered associative container are organized into *buckets*. Keys with the same hash code appear in the same bucket. The number of buckets is automatically increased as elements are added to an unordered associative container, so that the average number of elements per bucket is kept below a bound. Rehashing invalidates iterators, changes ordering between elements, and changes which buckets elements appear in, but does not invalidate pointers or references to elements. For `unordered_multiset` and `unordered_multimap`, rehashing preserves the relative ordering of equivalent elements.

10 In this subclause,

(10.1) — `X` denotes an unordered associative container class,

(10.2) — `a` denotes a value of type `X`,

(10.3) — `a2` denotes a value of a type with nodes compatible with type `X` (Table 75),

(10.4) — `b` denotes a value of type `X` or `const X`,

(10.5) — `a_uniq` denotes a value of type `X` when `X` supports unique keys,

(10.6) — `a_eq` denotes a value of type `X` when `X` supports equivalent keys,

(10.7) — `a_tran` denotes a value of type `X` or `const X` when the *qualified-id*s `X::key_equal::is_transparent` and `X::hasher::is_transparent` are both valid and denote types (13.10.3),

(10.8) — `i` and `j` denote input iterators that refer to `value_type`,

(10.9) — [`i`, `j`) denotes a valid range,

(10.10) — `rg` denotes a value of a type `R` that models *`container-compatible-range`*`<value_type>`,

(10.11) — `p` and `q2` denote valid constant iterators to `a`,

(10.12) — `q` and `q1` denote valid dereferenceable constant iterators to `a`,

(10.13) — `r` denotes a valid dereferenceable iterator to `a`,

(10.14) — [`q1`, `q2`) denotes a valid range in `a`,

(10.15) — `il` denotes a value of type `initializer_list<value_type>`,

(10.16) — `t` denotes a value of type `X::value_type`,

(10.17) — `k` denotes a value of type `key_type`,

(10.18) — `hf` denotes a value of type `hasher` or `const hasher`,

(10.19) — `eq` denotes a value of type `key_equal` or `const key_equal`,

(10.20) — `ke` is a value such that

(10.20.1) — `eq(r1, ke) == eq(ke, r1)`,

(10.20.2) — `hf(r1) == hf(ke)` if `eq(r1, ke)` is `true`, and

(10.20.3) — if any two of `eq(r1, ke)`, `eq(r2, ke)`, and `eq(r1, r2)` are `true`, then all three are `true`,

where `r1` and `r2` are keys of elements in `a_tran`,

(10.21) — `kx` is a value such that

(10.21.1) — `eq(r1, kx) == eq(kx, r1)`,

(10.21.2) — `hf(r1) == hf(kx)` if `eq(r1, kx)` is `true`,

(10.21.3) — if any two of `eq(r1, kx)`, `eq(r2, kx)`, and `eq(r1, r2)` are `true`, then all three are `true`, and

(10.21.4) — `kx` is not convertible to either `iterator` or `const_iterator`,

where `r1` and `r2` are keys of elements in `a_tran`,

(10.22) — `n` denotes a value of type `size_type`,

(10.23) — `z` denotes a value of type `float`, and

(10.24) — `nh` denotes an rvalue of type `X::node_type`.

11 A type `X` meets the *unordered associative container* requirements if `X` meets all the requirements of an allocator-aware container (23.2.2.5) and the following types, statements, and expressions are well-formed and have the specified semantics, except that for `unordered_map` and `unordered_multimap`, the requirements placed on `value_type` in 23.2.2.2 apply instead to `key_type` and `mapped_type`.

[*Note 3*: For example, `key_type` and `mapped_type` sometimes need to be *Cpp17CopyAssignable* even though the associated `value_type`, `pair<const key_type, mapped_type>`, is not *Cpp17CopyAssignable*. — *end note*]

`typename X::key_type`

12 *Result*: `Key`.

`typename X::mapped_type`

13 *Result*: `T`.

14 *Remarks*: For `unordered_map` and `unordered_multimap` only.

`typename X::value_type`

15 *Result*: `Key` for `unordered_set` and `unordered_multiset` only; `pair<const Key, T>` for `unordered_map` and `unordered_multimap` only.

16 *Preconditions*: `value_type` is *Cpp17Erasable* from `X`.

`typename X::hasher`

17 *Result*: `Hash`.

18 *Preconditions*: `Hash` is a unary function object type such that the expression `hf(k)` has type `size_t`.

`typename X::key_equal`

19 *Result*: `Pred`.

20 *Preconditions*: `Pred` meets the *Cpp17CopyConstructible* requirements. `Pred` is a binary predicate that takes two arguments of type `Key`. `Pred` is an equivalence relation.

`typename X::local_iterator`

21 *Result*: An iterator type whose category, value type, difference type, and pointer and reference types are the same as `X::iterator`'s.

[*Note 4*: A `local_iterator` object can be used to iterate through a single bucket, but cannot be used to iterate across buckets. — *end note*]

`typename X::const_local_iterator`

22 *Result*: An iterator type whose category, value type, difference type, and pointer and reference types are the same as `X::const_iterator`'s.

[*Note 5*: A `const_local_iterator` object can be used to iterate through a single bucket, but cannot be used to iterate across buckets. — *end note*]

`typename X::node_type`

23 *Result*: A specialization of a ***node-handle*** class template (23.2.5), such that the public nested types are the same types as the corresponding types in `X`.

`X(n, hf, eq)`

24 *Effects*: Constructs an empty container with at least `n` buckets, using `hf` as the hash function and `eq` as the key equality predicate.

25 *Complexity*: $\mathcal{O}$(`n`)

`X(n, hf)`

26 *Preconditions*: `key_equal` meets the *Cpp17DefaultConstructible* requirements.

27 *Effects*: Constructs an empty container with at least `n` buckets, using `hf` as the hash function and `key_equal()` as the key equality predicate.

28 *Complexity*: $\mathcal{O}$(`n`)

`X(n)`

29 *Preconditions*: `hasher` and `key_equal` meet the *Cpp17DefaultConstructible* requirements.

30 *Effects*: Constructs an empty container with at least `n` buckets, using `hasher()` as the hash function and `key_equal()` as the key equality predicate.

31 *Complexity*: $\mathcal{O}$(`n`)

```
X a = X();
X a;
```

32 *Preconditions*: `hasher` and `key_equal` meet the *Cpp17DefaultConstructible* requirements.

33 *Effects*: Constructs an empty container with an unspecified number of buckets, using `hasher()` as the hash function and `key_equal()` as the key equality predicate.

34 *Complexity*: Constant.

`X(i, j, n, hf, eq)`

35 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `X` from `*i`.

36 *Effects*: Constructs an empty container with at least `n` buckets, using `hf` as the hash function and `eq` as the key equality predicate, and inserts elements from [`i`, `j`) into it.

37 *Complexity*: Average case $\mathcal{O}(N)$ (N is `distance(i, j)`), worst case $\mathcal{O}(N^2)$.

`X(i, j, n, hf)`

38 *Preconditions*: `key_equal` meets the *Cpp17DefaultConstructible* requirements. `value_type` is *Cpp17EmplaceConstructible* into `X` from `*i`.

39 *Effects*: Constructs an empty container with at least `n` buckets, using `hf` as the hash function and `key_equal()` as the key equality predicate, and inserts elements from [`i`, `j`) into it.

40 *Complexity*: Average case $\mathcal{O}(N)$ (N is `distance(i, j)`), worst case $\mathcal{O}(N^2)$.

`X(i, j, n)`

41 *Preconditions*: `hasher` and `key_equal` meet the *Cpp17DefaultConstructible* requirements. `value_type` is *Cpp17EmplaceConstructible* into `X` from `*i`.

42 *Effects*: Constructs an empty container with at least `n` buckets, using `hasher()` as the hash function and `key_equal()` as the key equality predicate, and inserts elements from [`i`, `j`) into it.

43 *Complexity*: Average case $\mathcal{O}(N)$ (N is `distance(i, j)`), worst case $\mathcal{O}(N^2)$.

`X(i, j)`

44 *Preconditions*: `hasher` and `key_equal` meet the *Cpp17DefaultConstructible* requirements. `value_type` is *Cpp17EmplaceConstructible* into `X` from `*i`.

45 *Effects*: Constructs an empty container with an unspecified number of buckets, using `hasher()` as the hash function and `key_equal()` as the key equality predicate, and inserts elements from [`i`, `j`) into it.

46 *Complexity*: Average case $\mathcal{O}(N)$ (N is `distance(i, j)`), worst case $\mathcal{O}(N^2)$.

`X(from_range, rg, n, hf, eq)`

47 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`.

48 *Effects*: Constructs an empty container with at least `n` buckets, using `hf` as the hash function and `eq` as the key equality predicate, and inserts elements from `rg` into it.

49 *Complexity*: Average case $\mathcal{O}(N)$ (N is `ranges::distance(rg)`), worst case $\mathcal{O}(N^2)$.

`X(from_range, rg, n, hf)`

50 *Preconditions*: `key_equal` meets the *Cpp17DefaultConstructible* requirements. `value_type` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`.

51 *Effects*: Constructs an empty container with at least `n` buckets, using `hf` as the hash function and `key_equal()` as the key equality predicate, and inserts elements from `rg` into it.

52 *Complexity*: Average case $\mathcal{O}(N)$ (N is `ranges::distance(rg)`), worst case $\mathcal{O}(N^2)$.

`X(from_range, rg, n)`

53 *Preconditions*: `hasher` and `key_equal` meet the *Cpp17DefaultConstructible* requirements. `value_type` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`.

54 *Effects*: Constructs an empty container with at least `n` buckets, using `hasher()` as the hash function and `key_equal()` as the key equality predicate, and inserts elements from `rg` into it.

55 *Complexity*: Average case $\mathcal{O}(N)$ (N is `ranges::distance(rg)`), worst case $\mathcal{O}(N^2)$.

`X(from_range, rg)`

56 *Preconditions*: `hasher` and `key_equal` meet the *Cpp17DefaultConstructible* requirements. `value_type` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`.

57 *Effects*: Constructs an empty container with an unspecified number of buckets, using `hasher()` as the hash function and `key_equal()` as the key equality predicate, and inserts elements from `rg` into it.

58 *Complexity*: Average case $\mathcal{O}(N)$ (N is `ranges::distance(rg)`), worst case $\mathcal{O}(N^2)$.

`X(il)`

59 *Effects*: Equivalent to `X(il.begin(), il.end())`.

`X(il, n)`

60 *Effects*: Equivalent to `X(il.begin(), il.end(), n)`.

`X(il, n, hf)`

61 *Effects*: Equivalent to `X(il.begin(), il.end(), n, hf)`.

`X(il, n, hf, eq)`

62 *Effects*: Equivalent to `X(il.begin(), il.end(), n, hf, eq)`.

`X(b)`

63 *Effects*: In addition to the container requirements (23.2.2.2), copies the hash function, predicate, and maximum load factor.

64 *Complexity*: Average case linear in `b.size()`, worst case quadratic.

`a = b`

65 *Result*: `X&`

66 *Effects*: In addition to the container requirements, copies the hash function, predicate, and maximum load factor.

67 *Complexity*: Average case linear in `b.size()`, worst case quadratic.

`a = il`

68 *Result*: `X&`

69 *Preconditions*: `value_type` is *Cpp17CopyInsertable* into `X` and *Cpp17CopyAssignable*.

70 *Effects*: Assigns the range [`il.begin()`, `il.end()`) into `a`. All existing elements of `a` are either assigned to or destroyed.

71 *Complexity*: Average case linear in `il.size()`, worst case quadratic.

`b.hash_function()`

72 *Result*: `hasher`

73 *Returns*: `b`'s hash function.

74 *Complexity*: Constant.

`b.key_eq()`

75 *Result*: `key_equal`

76 *Returns*: `b`'s key equality predicate.

77 *Complexity*: Constant.

`a_uniq.emplace(args)`

78 *Result*: `pair<iterator, bool>`

79 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `X` from `args`.

80 *Effects*: Inserts a `value_type` object `t` constructed with `std::forward<Args>(args)...` if and only if there is no element in the container with key equivalent to the key of `t`.

81 *Returns*: The `bool` component of the returned pair is `true` if and only if the insertion takes place, and the iterator component of the pair points to the element with key equivalent to the key of `t`.

82 *Complexity*: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a_uniq.size()`).

`a_eq.emplace(args)`

83 *Result*: `iterator`

84 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `X` from `args`.

85 *Effects*: Inserts a `value_type` object `t` constructed with `std::forward<Args>(args)...`.

86 *Returns*: An iterator pointing to the newly inserted element.

87 *Complexity*: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a_eq.size()`).

`a.emplace_hint(p, args)`

88 *Result*: `iterator`

89 *Effects*: Equivalent to `a.emplace(std::forward<Args>(args)...)`, except that the `const_iterator p` is a hint pointing to where the search should start. Implementations are permitted to ignore the hint.

90 *Returns*: The iterator returned by `emplace`.

`a_uniq.insert(t)`

91 *Result*: `pair<iterator, bool>`

92 *Preconditions*: If `t` is a non-const rvalue, `value_type` is *Cpp17MoveInsertable* into `X`; otherwise, `value_type` is *Cpp17CopyInsertable* into `X`.

93 *Effects*: Inserts `t` if and only if there is no element in the container with key equivalent to the key of `t`.

94 *Returns*: The `bool` component of the returned pair indicates whether the insertion takes place, and the `iterator` component points to the element with key equivalent to the key of `t`.

95 *Complexity*: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a_uniq.size()`).

`a_eq.insert(t)`

96 *Result*: `iterator`

97 *Preconditions*: If `t` is a non-const rvalue, `value_type` is *Cpp17MoveInsertable* into `X`; otherwise, `value_type` is *Cpp17CopyInsertable* into `X`.

98 *Effects*: Inserts `t`.

99 *Returns*: An iterator pointing to the newly inserted element.

100 *Complexity*: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a_eq.size()`).

`a.insert(p, t)`

101 *Result*: `iterator`

102 *Preconditions*: If `t` is a non-const rvalue, `value_type` is *Cpp17MoveInsertable* into `X`; otherwise, `value_type` is *Cpp17CopyInsertable* into `X`.

103 *Effects*: Equivalent to `a.insert(t)`. The iterator `p` is a hint pointing to where the search should start. Implementations are permitted to ignore the hint.

104 *Returns*: An iterator pointing to the element with the key equivalent to that of `t`.

105 *Complexity*: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a.size()`).

`a.insert(i, j)`

106 *Result*: `void`

107 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `X` from `*i`. Neither `i` nor `j` are iterators into `a`.

108 *Effects*: Equivalent to `a.insert(t)` for each element in $[$`i`, `j`$)$.

109 *Complexity*: Average case $\mathcal{O}(N)$, where N is `distance(i, j)`, worst case $\mathcal{O}(N($`a.size()` $+ 1))$.

`a.insert_range(rg)`

110 *Result*: `void`

111 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `X` from `*ranges::begin(rg)`. `rg` and `a` do not overlap.

112 *Effects*: Equivalent to `a.insert(t)` for each element `t` in `rg`.

113 *Complexity*: Average case $\mathcal{O}(N)$, where N is `ranges::distance(rg)`, worst case $\mathcal{O}(N($`a.size()` $+ 1))$.

`a.insert(il)`

114 *Effects*: Equivalent to `a.insert(il.begin(), il.end())`.

`a_uniq.insert(nh)`

115 *Result*: `insert_return_type`

116 *Preconditions*: `nh` is empty or `a_uniq.get_allocator() == nh.get_allocator()` is `true`.

117 *Effects*: If `nh` is empty, has no effect. Otherwise, inserts the element owned by `nh` if and only if there is no element in the container with a key equivalent to `nh.key()`.

118 *Postconditions*: If `nh` is empty, `inserted` is `false`, `position` is `end()`, and `node` is empty. Otherwise if the insertion took place, `inserted` is `true`, `position` points to the inserted element, and `node` is empty; if the insertion failed, `inserted` is `false`, `node` has the previous value of `nh`, and `position` points to an element with a key equivalent to `nh.key()`.

119 *Complexity*: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a_uniq.size()`).

`a_eq.insert(nh)`

120 *Result*: `iterator`

121 *Preconditions*: `nh` is empty or `a_eq.get_allocator() == nh.get_allocator()` is `true`.

122 *Effects*: If `nh` is empty, has no effect and returns `a_eq.end()`. Otherwise, inserts the element owned by `nh` and returns an iterator pointing to the newly inserted element.

123 *Postconditions*: `nh` is empty.

124 *Complexity*: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a_eq.size()`).

`a.insert(q, nh)`

125 *Result*: `iterator`

126 *Preconditions*: `nh` is empty or `a.get_allocator() == nh.get_allocator()` is `true`.

127 *Effects*: If `nh` is empty, has no effect and returns `a.end()`. Otherwise, inserts the element owned by `nh` if and only if there is no element with key equivalent to `nh.key()` in containers with unique keys; always inserts the element owned by `nh` in containers with equivalent keys. The iterator `q` is a hint pointing to where the search should start. Implementations are permitted to ignore the hint.

128 *Postconditions*: `nh` is empty if insertion succeeds, unchanged if insertion fails.

129 *Returns*: An iterator pointing to the element with key equivalent to `nh.key()`.

130 *Complexity*: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a.size()`).

`a.extract(k)`

131 *Result*: `node_type`

132 *Effects*: Removes an element in the container with key equivalent to `k`.

133 *Returns*: A `node_type` owning the element if found, otherwise an empty `node_type`.

134 *Complexity*: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a.size()`).

`a_tran.extract(kx)`

135 *Result*: `node_type`

136 *Effects*: Removes an element in the container with key equivalent to `kx`.

137 *Returns*: A `node_type` owning the element if found, otherwise an empty `node_type`.

138 *Complexity*: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a_tran.size()`).

`a.extract(q)`

139 *Result*: `node_type`

140 *Effects*: Removes the element pointed to by `q`.

141 *Returns*: A `node_type` owning that element.

142 *Complexity*: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a.size()`).

`a.merge(a2)`

143 *Result*: `void`

144 *Preconditions*: `a.get_allocator() == a2.get_allocator()`.

145 *Effects*: Attempts to extract each element in `a2` and insert it into `a` using the hash function and key equality predicate of `a`. In containers with unique keys, if there is an element in `a` with key equivalent to the key of an element from `a2`, then that element is not extracted from `a2`.

146 *Postconditions*: Pointers and references to the transferred elements of `a2` refer to those same elements but as members of `a`. Iterators referring to the transferred elements and all iterators referring to `a` will be invalidated, but iterators to elements remaining in `a2` will remain valid.

147 *Complexity*: Average case $\mathcal{O}(N)$, where N is `a2.size()`, worst case $\mathcal{O}$(N`*a.size() + N`).

`a.erase(k)`

148 *Result*: `size_type`

149 *Effects*: Erases all elements with key equivalent to `k`.

150 *Returns*: The number of elements erased.

151 *Complexity*: Average case $\mathcal{O}$(`a.count(k)`), worst case $\mathcal{O}$(`a.size()`).

`a_tran.erase(kx)`

152 *Result*: `size_type`

153 *Effects*: Erases all elements with key equivalent to `kx`.

154 *Returns*: The number of elements erased.

155 *Complexity*: Average case $\mathcal{O}$(`a_tran.count(kx)`), worst case $\mathcal{O}$(`a_tran.size()`).

`a.erase(q)`

156 *Result*: `iterator`

157 *Effects*: Erases the element pointed to by `q`.

158 *Returns*: The iterator immediately following `q` prior to the erasure.

159 *Complexity*: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a.size()`).

`a.erase(r)`

160 *Result*: `iterator`

161 *Effects*: Erases the element pointed to by `r`.

162 *Returns*: The iterator immediately following `r` prior to the erasure.

163 *Complexity*: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a.size()`).

`a.erase(q1, q2)`

164 *Result*: `iterator`

165 *Effects*: Erases all elements in the range [`q1`, `q2`).

166 *Returns*: The iterator immediately following the erased elements prior to the erasure.

167 *Complexity*: Average case linear in `distance(q1, q2)`, worst case $\mathcal{O}$(`a.size()`).

`a.clear()`

168 *Result*: `void`

169 *Effects*: Erases all elements in the container.

170 *Postconditions*: `a.empty()` is `true`.

171 *Complexity*: Linear in `a.size()`.

`b.find(k)`

172 *Result*: `const_iterator` if `b` is of type `const X`; `iterator` otherwise.

173 *Returns*: An iterator pointing to an element with key equivalent to `k`, or `b.end()` if no such element exists.

174 *Complexity*: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`b.size()`).

`a_tran.find(ke)`

175 *Result*: `const_iterator` if `a_tran` is of type `const X`; `iterator` otherwise.

176 *Returns*: An iterator pointing to an element with key equivalent to `ke`, or `a_tran.end()` if no such element exists.

177 *Complexity*: Average case $\mathcal{O}(1)$, worst case $\mathcal{O}$(`a_tran.size()`).

`b.count(k)`

178 *Result*: `size_type`

179 *Returns*: The number of elements with key equivalent to `k`.

180 *Complexity*: Average case $\mathcal{O}$(`b.count(k)`), worst case $\mathcal{O}$(`b.size()`).

`a_tran.count(ke)`

181 *Result*: `size_type`

182 *Returns*: The number of elements with key equivalent to `ke`.

183 *Complexity*: Average case $\mathcal{O}$(`a_tran.count(ke)`), worst case $\mathcal{O}$(`a_tran.size()`).

`b.contains(k)`

184 *Effects*: Equivalent to `b.find(k) != b.end()`.

`a_tran.contains(ke)`

185 *Effects*: Equivalent to `a_tran.find(ke) != a_tran.end()`.

`b.equal_range(k)`

186 *Result*: `pair<const_iterator, const_iterator>` if `b` is of type `const X`; `pair<iterator, iterator>` otherwise.

187 *Returns*: A range containing all elements with keys equivalent to `k`. Returns `make_pair(b.end(), b.end())` if no such elements exist.

188 *Complexity*: Average case $\mathcal{O}$(`b.count(k)`), worst case $\mathcal{O}$(`b.size()`).

`a_tran.equal_range(ke)`

189 *Result*: `pair<const_iterator, const_iterator>` if `a_tran` is of type `const X`; `pair<iterator, iterator>` otherwise.

190 *Returns*: A range containing all elements with keys equivalent to `ke`. Returns `make_pair(a_tran.end(), a_tran.end())` if no such elements exist.

191 *Complexity*: Average case $\mathcal{O}$(`a_tran.count(ke)`), worst case $\mathcal{O}$(`a_tran.size()`).

`b.bucket_count()`

192 *Result*: `size_type`

193 *Returns*: The number of buckets that `b` contains.

194 *Complexity*: Constant.

`b.max_bucket_count()`

195 *Result*: `size_type`

196 *Returns*: An upper bound on the number of buckets that `b` can ever contain.

197 *Complexity*: Constant.

`b.bucket(k)`

198 *Result*: `size_type`

199 *Preconditions*: `b.bucket_count() > 0`.

200 *Returns*: The index of the bucket in which elements with keys equivalent to `k` would be found, if any such element existed. The return value is in the range [`0`, `b.bucket_count()`).

201 *Complexity*: Constant.

`a_tran.bucket(ke)`

202 *Result*: `size_type`

203 *Preconditions*: `a_tran.bucket_count() > 0`.

204 *Postconditions*: The return value is in the range [`0`, `a_tran.bucket_count()`).

205 *Returns*: The index of the bucket in which elements with keys equivalent to `ke` would be found, if any such element existed.

206 *Complexity*: Constant.

`b.bucket_size(n)`

207 *Result*: `size_type`

208 *Preconditions*: `n` shall be in the range [`0`, `b.bucket_count()`).

209 *Returns*: The number of elements in the $\texttt{n}^{\text{th}}$ bucket.

210 *Complexity*: $\mathcal{O}$(`b.bucket_size(n)`)

`b.begin(n)`

211 *Result*: `const_local_iterator` if `b` is of type `const X`; `local_iterator` otherwise.

212 *Preconditions*: `n` is in the range [`0`, `b.bucket_count()`).

213 *Returns*: An iterator referring to the first element in the bucket. If the bucket is empty, then `b.begin(n) == b.end(n)`.

214 *Complexity*: Constant.

`b.end(n)`

Result: `const_local_iterator` if `b` is of type `const X`; `local_iterator` otherwise.

Preconditions: `n` is in the range $[0, \texttt{b.bucket\_count()})$.

Returns: An iterator which is the past-the-end value for the bucket.

Complexity: Constant.

`b.cbegin(n)`

Result: `const_local_iterator`

Preconditions: `n` shall be in the range $[0, \texttt{b.bucket\_count()})$.

Returns: An iterator referring to the first element in the bucket. If the bucket is empty, then `b.cbegin(n) == b.cend(n)`.

Complexity: Constant.

`b.cend(n)`

Result: `const_local_iterator`

Preconditions: `n` is in the range $[0, \texttt{b.bucket\_count()})$.

Returns: An iterator which is the past-the-end value for the bucket.

Complexity: Constant.

`b.load_factor()`

Result: `float`

Returns: The average number of elements per bucket.

Complexity: Constant.

`b.max_load_factor()`

Result: `float`

Returns: A positive number that the container attempts to keep the load factor less than or equal to. The container automatically increases the number of buckets as necessary to keep the load factor below this number.

Complexity: Constant.

`a.max_load_factor(z)`

Result: `void`

Preconditions: `z` is positive. May change the container's maximum load factor, using `z` as a hint.

Complexity: Constant.

`a.rehash(n)`

Result: `void`

Postconditions: `a.bucket_count() >= a.size() / a.max_load_factor()` and `a.bucket_count() >= n`.

Complexity: Average case linear in `a.size()`, worst case quadratic.

`a.reserve(n)`

Effects: Equivalent to `a.rehash(ceil(n / a.max_load_factor()))`.

Two unordered containers `a` and `b` compare equal if `a.size() == b.size()` and, for every equivalent-key group $[\texttt{Ea1}, \texttt{Ea2})$ obtained from `a.equal_range(Ea1)`, there exists an equivalent-key group $[\texttt{Eb1}, \texttt{Eb2})$ obtained from `b.equal_range(Ea1)`, such that `is_permutation(Ea1, Ea2, Eb1, Eb2)` returns `true`. For `unordered_set` and `unordered_map`, the complexity of `operator==` (i.e., the number of calls to the `==` operator of the `value_type`, to the predicate returned by `key_eq()`, and to the hasher returned by `hash_function()`) is proportional to N in the average case and to N^2 in the worst case, where N is `a.size()`. For `unordered_multiset` and `unordered_multimap`, the complexity of `operator==` is proportional to $\sum E_i^2$ in the average case and to N^2 in the worst case, where N is `a.size()`, and E_i is the size of the i^{th} equivalent-key

group in `a`. However, if the respective elements of each corresponding pair of equivalent-key groups Ea_i and Eb_i are arranged in the same order (as is commonly the case, e.g., if `a` and `b` are unmodified copies of the same container), then the average-case complexity for `unordered_multiset` and `unordered_multimap` becomes proportional to N (but worst-case complexity remains $\mathcal{O}(N^2)$, e.g., for a pathologically bad hash function). The behavior of a program that uses `operator==` or `operator!=` on unordered containers is undefined unless the `Pred` function object has the same behavior for both containers and the equality comparison function for `Key` is a refinement[174] of the partition into equivalent-key groups produced by `Pred`.

241 The iterator types `iterator` and `const_iterator` of an unordered associative container are of at least the forward iterator category. For unordered associative containers where the key type and value type are the same, both `iterator` and `const_iterator` are constant iterators.

242 The `insert`, `insert_range`, and `emplace` members shall not affect the validity of references to container elements, but may invalidate all iterators to the container. The `erase` members shall invalidate only iterators and references to the erased elements, and preserve the relative order of the elements that are not erased.

243 The `insert`, `insert_range`, and `emplace` members shall not affect the validity of iterators if `(N + n) <= z * B`, where `N` is the number of elements in the container prior to the insert operation, `n` is the number of elements inserted, `B` is the container's bucket count, and `z` is the container's maximum load factor.

244 The `extract` members invalidate only iterators to the removed element, and preserve the relative order of the elements that are not erased; pointers and references to the removed element remain valid. However, accessing the element through such pointers and references while the element is owned by a `node_type` is undefined behavior. References and pointers to an element obtained while it is owned by a `node_type` are invalidated if the element is successfully inserted.

245 The member function templates `find`, `count`, `equal_range`, `contains`, `extract`, `erase`, and `bucket` shall not participate in overload resolution unless the *qualified-id*s `Pred::is_transparent` and `Hash::is_transparent` are both valid and denote types (13.10.3). Additionally, the member function templates `extract` and `erase` shall not participate in overload resolution if `is_convertible_v<K&&, iterator> || is_convertible_v<K&&, const_iterator>` is `true`, where `K` is the type substituted as the first template argument.

246 A deduction guide for an unordered associative container shall not participate in overload resolution if any of the following are true:

(246.1) — It has an `InputIterator` template parameter and a type that does not qualify as an input iterator is deduced for that parameter.

(246.2) — It has an `Allocator` template parameter and a type that does not qualify as an allocator is deduced for that parameter.

(246.3) — It has a `Hash` template parameter and an integral type or a type that qualifies as an allocator is deduced for that parameter.

(246.4) — It has a `Pred` template parameter and a type that qualifies as an allocator is deduced for that parameter.

23.2.8.2 Exception safety guarantees [unord.req.except]

1 For unordered associative containers, no `clear()` function throws an exception. `erase(k)` does not throw an exception unless that exception is thrown by the container's `Hash` or `Pred` object (if any).

2 For unordered associative containers, if an exception is thrown by any operation other than the container's hash function from within an `insert` or `emplace` function inserting a single element, the insertion has no effect.

3 For unordered associative containers, no `swap` function throws an exception unless that exception is thrown by the swap of the container's `Hash` or `Pred` object (if any).

4 For unordered associative containers, if an exception is thrown from within a `rehash()` function other than by the container's hash function or comparison function, the `rehash()` function has no effect.

23.3 Sequence containers [sequences]

23.3.1 General [sequences.general]

1 The headers `<array>` (23.3.2), `<deque>` (23.3.4), `<forward_list>` (23.3.6), `<hive>` (23.3.8), `<inplace_vector>` (23.3.15), `<list>` (23.3.10), and `<vector>` (23.3.12) define class templates that meet the requirements for sequence containers.

174) Equality comparison is a refinement of partitioning if no two objects that compare equal fall into different partitions.

[2] The following exposition-only alias template may appear in deduction guides for sequence containers:

```
template<class InputIterator>
  using iter-value-type = iterator_traits<InputIterator>::value_type;  // exposition only
```

23.3.2 Header <array> synopsis [array.syn]

```
// mostly freestanding
#include <compare>              // see 17.12.1
#include <initializer_list>     // see 17.11.2

namespace std {
  // 23.3.3, class template array
  template<class T, size_t N> struct array;                              // partially freestanding

  template<class T, size_t N>
    constexpr bool operator==(const array<T, N>& x, const array<T, N>& y);
  template<class T, size_t N>
    constexpr synth-three-way-result<T>
      operator<=>(const array<T, N>& x, const array<T, N>& y);

  // 23.3.3.4, specialized algorithms
  template<class T, size_t N>
    constexpr void swap(array<T, N>& x, array<T, N>& y) noexcept(noexcept(x.swap(y)));

  // 23.3.3.6, array creation functions
  template<class T, size_t N>
    constexpr array<remove_cv_t<T>, N> to_array(T (&a)[N]);
  template<class T, size_t N>
    constexpr array<remove_cv_t<T>, N> to_array(T (&&a)[N]);

  // 23.3.3.7, tuple interface
  template<class T> struct tuple_size;
  template<size_t I, class T> struct tuple_element;
  template<class T, size_t N>
    struct tuple_size<array<T, N>>;
  template<size_t I, class T, size_t N>
    struct tuple_element<I, array<T, N>>;
  template<size_t I, class T, size_t N>
    constexpr T& get(array<T, N>&) noexcept;
  template<size_t I, class T, size_t N>
    constexpr T&& get(array<T, N>&&) noexcept;
  template<size_t I, class T, size_t N>
    constexpr const T& get(const array<T, N>&) noexcept;
  template<size_t I, class T, size_t N>
    constexpr const T&& get(const array<T, N>&&) noexcept;
}
```

23.3.3 Class template array [array]

23.3.3.1 Overview [array.overview]

[1] The header <array> defines a class template for storing fixed-size sequences of objects. An array is a contiguous container (23.2.2.2). An instance of array<T, N> stores N elements of type T, so that size() == N is an invariant.

[2] An array is an aggregate (9.5.2) that can be list-initialized with up to N elements whose types are convertible to T.

[3] An array meets all of the requirements of a container (23.2.2.2) and of a reversible container (23.2.2.3), except that a default constructed array object is not empty if N > 0. An array meets some of the requirements of a sequence container (23.2.4). Descriptions are provided here only for operations on array that are not described in one of these tables and for operations where there is additional semantic information.

[4] array<T, N> is a structural type (13.2) if T is a structural type. Two values a1 and a2 of type array<T, N> are template-argument-equivalent (13.6) if and only if each pair of corresponding elements in a1 and a2 are template-argument-equivalent.

5 The types `iterator` and `const_iterator` meet the constexpr iterator requirements (24.3.1).

```
namespace std {
  template<class T, size_t N>
  struct array {
    // types
    using value_type             = T;
    using pointer                = T*;
    using const_pointer          = const T*;
    using reference              = T&;
    using const_reference        = const T&;

    using iterator               = implementation-defined; // see 23.2
    using const_iterator         = implementation-defined; // see 23.2
    using reverse_iterator       = std::reverse_iterator<iterator>;
    using const_reverse_iterator = std::reverse_iterator<const_iterator>;

    // no explicit construct/copy/destroy for aggregate type

    constexpr void fill(const T& u);
    constexpr void swap(array&) noexcept(is_nothrow_swappable_v<T>);

    // iterators
    constexpr iterator               begin() noexcept;
    constexpr const_iterator         begin() const noexcept;
    constexpr iterator               end() noexcept;
    constexpr const_iterator         end() const noexcept;

    constexpr reverse_iterator       rbegin() noexcept;
    constexpr const_reverse_iterator rbegin() const noexcept;
    constexpr reverse_iterator       rend() noexcept;
    constexpr const_reverse_iterator rend() const noexcept;

    constexpr const_iterator         cbegin() const noexcept;
    constexpr const_iterator         cend() const noexcept;
    constexpr const_reverse_iterator crbegin() const noexcept;
    constexpr const_reverse_iterator crend() const noexcept;

    // capacity
    constexpr bool empty() const noexcept;
    constexpr size_type size() const noexcept;
    constexpr size_type max_size() const noexcept;

    // element access
    constexpr reference       operator[](size_type n);
    constexpr const_reference operator[](size_type n) const;
    constexpr reference       at(size_type n);                    // freestanding-deleted
    constexpr const_reference at(size_type n) const;              // freestanding-deleted
    constexpr reference       front();
    constexpr const_reference front() const;
    constexpr reference       back();
    constexpr const_reference back() const;

    constexpr T*       data() noexcept;
    constexpr const T* data() const noexcept;
  };

  template<class T, class... U>
    array(T, U...) -> array<T, 1 + sizeof...(U)>;
}
```

23.3.3.2 Constructors, copy, and assignment [array.cons]

1 An `array` relies on the implicitly-declared special member functions (11.4.5.2, 11.4.7, 11.4.5.3) to conform to the container requirements table in 23.2. In addition to the requirements specified in the container requirements table, the implicitly-declared move constructor and move assignment operator for `array` require that `T` be *Cpp17MoveConstructible* or *Cpp17MoveAssignable*, respectively.

```
template<class T, class... U>
  array(T, U...) -> array<T, 1 + sizeof...(U)>;
```

2 *Mandates*: `(is_same_v<T, U> && ...)` is `true`.

23.3.3.3 Member functions [array.members]

```
constexpr size_type size() const noexcept;
```

1 *Returns*: `N`.

```
constexpr T* data() noexcept;
constexpr const T* data() const noexcept;
```

2 *Returns*: A pointer such that `[data(),data() + size())` is a valid range. For a non-empty array, `data() == addressof(front())` is `true`.

```
constexpr void fill(const T& u);
```

3 *Effects*: As if by `fill_n(begin(), N, u)`.

```
constexpr void swap(array& y) noexcept(is_nothrow_swappable_v<T>);
```

4 *Effects*: Equivalent to `swap_ranges(begin(), end(), y.begin())`.

5 [*Note 1*: Unlike the `swap` function for other containers, `array::swap` takes linear time, can exit via an exception, and does not cause iterators to become associated with the other container. — *end note*]

23.3.3.4 Specialized algorithms [array.special]

```
template<class T, size_t N>
  constexpr void swap(array<T, N>& x, array<T, N>& y) noexcept(noexcept(x.swap(y)));
```

1 *Constraints*: `N == 0` or `is_swappable_v<T>` is `true`.

2 *Effects*: As if by `x.swap(y)`.

3 *Complexity*: Linear in `N`.

23.3.3.5 Zero-sized arrays [array.zero]

1 `array` shall provide support for the special case `N == 0`.

2 In the case that `N == 0`, `begin() == end()` == unique value. The return value of `data()` is unspecified.

3 Member function `swap()` shall have a non-throwing exception specification.

23.3.3.6 Array creation functions [array.creation]

```
template<class T, size_t N>
  constexpr array<remove_cv_t<T>, N> to_array(T (&a)[N]);
```

1 *Mandates*: `is_array_v<T>` is `false` and `is_constructible_v<remove_cv_t<T>, T&>` is `true`.

2 *Preconditions*: `T` meets the *Cpp17CopyConstructible* requirements.

3 *Returns*: `{{ a[0], ..., a[N - 1] }}`.

```
template<class T, size_t N>
  constexpr array<remove_cv_t<T>, N> to_array(T (&&a)[N]);
```

4 *Mandates*: `is_array_v<T>` is `false` and `is_constructible_v<remove_cv_t<T>, T>` is `true`.

5 *Preconditions*: `T` meets the *Cpp17MoveConstructible* requirements.

6 *Returns*: `{{ std::move(a[0]), ..., std::move(a[N - 1]) }}`.

23.3.3.7 Tuple interface [array.tuple]

```
template<class T, size_t N>
  struct tuple_size<array<T, N>> : integral_constant<size_t, N> { };

template<size_t I, class T, size_t N>
  struct tuple_element<I, array<T, N>> {
    using type = T;
  };
```

1 *Mandates*: `I < N` is `true`.

```
template<size_t I, class T, size_t N>
  constexpr T& get(array<T, N>& a) noexcept;
template<size_t I, class T, size_t N>
  constexpr T&& get(array<T, N>&& a) noexcept;
template<size_t I, class T, size_t N>
  constexpr const T& get(const array<T, N>& a) noexcept;
template<size_t I, class T, size_t N>
  constexpr const T&& get(const array<T, N>&& a) noexcept;
```

2 *Mandates*: `I < N` is `true`.

3 *Returns*: A reference to the $\texttt{I}^{\text{th}}$ element of `a`, where indexing is zero-based.

23.3.4 Header <deque> synopsis [deque.syn]

```
#include <compare>             // see 17.12.1
#include <initializer_list>    // see 17.11.2

namespace std {
  // 23.3.5, class template deque
  template<class T, class Allocator = allocator<T>> class deque;

  template<class T, class Allocator>
    constexpr bool operator==(const deque<T, Allocator>& x, const deque<T, Allocator>& y);
  template<class T, class Allocator>
    constexpr synth-three-way-result<T>
      operator<=>(const deque<T, Allocator>& x, const deque<T, Allocator>& y);

  template<class T, class Allocator>
    constexpr void swap(deque<T, Allocator>& x, deque<T, Allocator>& y)
      noexcept(noexcept(x.swap(y)));

  // 23.3.5.5, erasure
  template<class T, class Allocator, class U = T>
    constexpr typename deque<T, Allocator>::size_type
      erase(deque<T, Allocator>& c, const U& value);
  template<class T, class Allocator, class Predicate>
    constexpr typename deque<T, Allocator>::size_type
      erase_if(deque<T, Allocator>& c, Predicate pred);

  namespace pmr {
    template<class T>
      using deque = std::deque<T, polymorphic_allocator<T>>;
  }
}
```

23.3.5 Class template deque [deque]

23.3.5.1 Overview [deque.overview]

1 A `deque` is a sequence container that supports random access iterators (24.3.5.7). In addition, it supports constant time insert and erase operations at the beginning or the end; insert and erase in the middle take linear time. That is, a deque is especially optimized for pushing and popping elements at the beginning and end. Storage management is handled automatically.

[2] A `deque` meets all of the requirements of a container (23.2.2.2), of a reversible container (23.2.2.3), of an allocator-aware container (23.2.2.5), and of a sequence container, including the optional sequence container requirements (23.2.4). Descriptions are provided here only for operations on `deque` that are not described in one of these tables or for operations where there is additional semantic information.

[3] The types `iterator` and `const_iterator` meet the constexpr iterator requirements (24.3.1).

```
namespace std {
  template<class T, class Allocator = allocator<T>>
  class deque {
  public:
    // types
    using value_type             = T;
    using allocator_type         = Allocator;
    using pointer                = allocator_traits<Allocator>::pointer;
    using const_pointer          = allocator_traits<Allocator>::const_pointer;
    using reference              = value_type&;
    using const_reference        = const value_type&;
    using size_type              = implementation-defined; // see 23.2
    using difference_type        = implementation-defined; // see 23.2
    using iterator               = implementation-defined; // see 23.2
    using const_iterator         = implementation-defined; // see 23.2
    using reverse_iterator       = std::reverse_iterator<iterator>;
    using const_reverse_iterator = std::reverse_iterator<const_iterator>;

    // 23.3.5.2, construct/copy/destroy
    constexpr deque() : deque(Allocator()) { }
    constexpr explicit deque(const Allocator&);
    constexpr explicit deque(size_type n, const Allocator& = Allocator());
    constexpr deque(size_type n, const T& value, const Allocator& = Allocator());

    template<class... Args> constexpr reference emplace_front(Args&&... args);
    template<class... Args> constexpr reference emplace_back(Args&&... args);
    template<class... Args> constexpr iterator emplace(const_iterator position, Args&&... args);

    constexpr void push_front(const T& x);
    constexpr void push_front(T&& x);
    template<container-compatible-range<T> R>
      constexpr void prepend_range(R&& rg);
    constexpr void push_back(const T& x);
    constexpr void push_back(T&& x);
    template<container-compatible-range<T> R>
      constexpr void append_range(R&& rg);

    constexpr iterator insert(const_iterator position, const T& x);
    constexpr iterator insert(const_iterator position, T&& x);
    constexpr iterator insert(const_iterator position, size_type n, const T& x);
    template<class InputIterator>
      constexpr iterator insert(const_iterator position,
                                InputIterator first, InputIterator last);
    template<container-compatible-range<T> R>
      constexpr iterator insert_range(const_iterator position, R&& rg);
    constexpr iterator insert(const_iterator position, initializer_list<T>);

    constexpr void pop_front();
    constexpr void pop_back();

    constexpr iterator erase(const_iterator position);
    constexpr iterator erase(const_iterator first, const_iterator last);
    constexpr void     swap(deque&)
      noexcept(allocator_traits<Allocator>::is_always_equal::value);
    constexpr void     clear() noexcept;
  };

  template<class InputIterator, class Allocator = allocator<iter-value-type<InputIterator>>>
    deque(InputIterator, InputIterator, Allocator = Allocator())
      -> deque<iter-value-type<InputIterator>, Allocator>;

  template<ranges::input_range R, class Allocator = allocator<ranges::range_value_t<R>>>
    deque(from_range_t, R&&, Allocator = Allocator())
      -> deque<ranges::range_value_t<R>, Allocator>;
}
```

23.3.5.2 Constructors, copy, and assignment [deque.cons]

```
constexpr explicit deque(const Allocator&);
```

1 *Effects*: Constructs an empty `deque`, using the specified allocator.

2 *Complexity*: Constant.

```
constexpr explicit deque(size_type n, const Allocator& = Allocator());
```

3 *Preconditions*: `T` is *Cpp17DefaultInsertable* into `deque`.

4 *Effects*: Constructs a `deque` with `n` default-inserted elements using the specified allocator.

5 *Complexity*: Linear in `n`.

```
constexpr deque(size_type n, const T& value, const Allocator& = Allocator());
```

6 *Preconditions*: `T` is *Cpp17CopyInsertable* into `deque`.

7 *Effects*: Constructs a `deque` with `n` copies of `value`, using the specified allocator.

8 *Complexity*: Linear in `n`.

```
template<class InputIterator>
  constexpr deque(InputIterator first, InputIterator last, const Allocator& = Allocator());
```

9 *Effects*: Constructs a `deque` equal to the range [`first`, `last`), using the specified allocator.

10 *Complexity*: Linear in `distance(first, last)`.

```
template<container-compatible-range<T> R>
  constexpr deque(from_range_t, R&& rg, const Allocator& = Allocator());
```

11 *Effects*: Constructs a `deque` with the elements of the range `rg`, using the specified allocator.

12 *Complexity*: Linear in `ranges::distance(rg)`.

23.3.5.3 Capacity [deque.capacity]

```
constexpr void resize(size_type sz);
```

1 *Preconditions*: `T` is *Cpp17MoveInsertable* and *Cpp17DefaultInsertable* into `deque`.

2 *Effects*: If `sz < size()`, erases the last `size() - sz` elements from the sequence. Otherwise, appends `sz - size()` default-inserted elements to the sequence.

```
constexpr void resize(size_type sz, const T& c);
```

3 *Preconditions*: `T` is *Cpp17CopyInsertable* into `deque`.

4 *Effects*: If `sz < size()`, erases the last `size() - sz` elements from the sequence. Otherwise, appends `sz - size()` copies of `c` to the sequence.

```
constexpr void shrink_to_fit();
```

5 *Preconditions*: `T` is *Cpp17MoveInsertable* into `deque`.

6 *Effects*: `shrink_to_fit` is a non-binding request to reduce memory use but does not change the size of the sequence.

[*Note 1*: The request is non-binding to allow latitude for implementation-specific optimizations. — *end note*]

If the size is equal to the old capacity, or if an exception is thrown other than by the move constructor of a non-*Cpp17CopyInsertable* `T`, then there are no effects.

7 *Complexity*: If the size is not equal to the old capacity, linear in the size of the sequence; otherwise constant.

8 *Remarks*: If the size is not equal to the old capacity, then invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator.

23.3.5.4 Modifiers [deque.modifiers]

```
constexpr iterator insert(const_iterator position, const T& x);
constexpr iterator insert(const_iterator position, T&& x);
constexpr iterator insert(const_iterator position, size_type n, const T& x);
```

```
template<class InputIterator>
  constexpr iterator insert(const_iterator position,
                            InputIterator first, InputIterator last);
template<container-compatible-range<T> R>
  constexpr iterator insert_range(const_iterator position, R&& rg);
constexpr iterator insert(const_iterator position, initializer_list<T>);

template<class... Args> constexpr reference emplace_front(Args&&... args);
template<class... Args> constexpr reference emplace_back(Args&&... args);
template<class... Args> constexpr iterator emplace(const_iterator position, Args&&... args);
constexpr void push_front(const T& x);
constexpr void push_front(T&& x);
template<container-compatible-range<T> R>
  constexpr void prepend_range(R&& rg);
constexpr void push_back(const T& x);
constexpr void push_back(T&& x);
template<container-compatible-range<T> R>
  constexpr void append_range(R&& rg);
```

1 *Effects*: An insertion in the middle of the deque invalidates all the iterators and references to elements of the deque. An insertion at either end of the deque invalidates all the iterators to the deque, but has no effect on the validity of references to elements of the deque.

2 *Complexity*: The complexity is linear in the number of elements inserted plus the lesser of the distances to the beginning and end of the deque. Inserting a single element at either the beginning or end of a deque always takes constant time and causes a single call to a constructor of `T`.

3 *Remarks*: If an exception is thrown other than by the copy constructor, move constructor, assignment operator, or move assignment operator of `T`, there are no effects. If an exception is thrown while inserting a single element at either end, there are no effects. Otherwise, if an exception is thrown by the move constructor of a non-*Cpp17CopyInsertable* `T`, the effects are unspecified.

```
constexpr iterator erase(const_iterator position);
constexpr iterator erase(const_iterator first, const_iterator last);
constexpr void pop_front();
constexpr void pop_back();
```

4 *Effects*: An erase operation that erases the last element of a deque invalidates only the past-the-end iterator and all iterators and references to the erased elements. An erase operation that erases the first element of a deque but not the last element invalidates only iterators and references to the erased elements. An erase operation that erases neither the first element nor the last element of a deque invalidates the past-the-end iterator and all iterators and references to all the elements of the deque.

[*Note 1*: `pop_front` and `pop_back` are erase operations. — *end note*]

5 *Throws*: Nothing unless an exception is thrown by the assignment operator of `T`.

6 *Complexity*: The number of calls to the destructor of `T` is the same as the number of elements erased, but the number of calls to the assignment operator of `T` is no more than the lesser of the number of elements before the erased elements and the number of elements after the erased elements.

23.3.5.5 Erasure [deque.erasure]

```
template<class T, class Allocator, class U = T>
  constexpr typename deque<T, Allocator>::size_type
    erase(deque<T, Allocator>& c, const U& value);
```

1 *Effects*: Equivalent to:

```
auto it = remove(c.begin(), c.end(), value);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;
```

```
template<class T, class Allocator, class Predicate>
  constexpr typename deque<T, Allocator>::size_type
    erase_if(deque<T, Allocator>& c, Predicate pred);
```

2 *Effects*: Equivalent to:

```
    auto it = remove_if(c.begin(), c.end(), pred);
    auto r = distance(it, c.end());
    c.erase(it, c.end());
    return r;
```

23.3.6 Header <forward_list> synopsis [forward.list.syn]

```
#include <compare>             // see 17.12.1
#include <initializer_list>    // see 17.11.2

    constexpr void swap(forward_list<T, Allocator>& x, forward_list<T, Allocator>& y)
      noexcept(noexcept(x.swap(y)));

  // 23.3.7.7, erasure
  template<class T, class Allocator, class U = T>
    constexpr typename forward_list<T, Allocator>::size_type
      erase(forward_list<T, Allocator>& c, const U& value);
  template<class T, class Allocator, class Predicate>
    constexpr typename forward_list<T, Allocator>::size_type
      erase_if(forward_list<T, Allocator>& c, Predicate pred);

  namespace pmr {
    template<class T>
      using forward_list = std::forward_list<T, polymorphic_allocator<T>>;
  }
}
```

23.3.7 Class template forward_list [forward.list]

23.3.7.1 Overview [forward.list.overview]

1 A `forward_list` is a container that supports forward iterators and allows constant time insert and erase operations anywhere within the sequence, with storage management handled automatically. Fast random access to list elements is not supported.

[*Note 1*: It is intended that `forward_list` have zero space or time overhead relative to a hand-written C-style singly linked list. Features that would conflict with that goal have been omitted. — *end note*]

2 A `forward_list` meets all of the requirements of a container (23.2.2.2), except that the `size()` member function is not provided and `operator==` has linear complexity. A `forward_list` also meets all of the requirements for an allocator-aware container (23.2.2.5). In addition, a `forward_list` provides the `assign` member functions and several of the optional sequence container requirements (23.2.4). Descriptions are provided here only for operations on `forward_list` that are not described in that table or for operations where there is additional semantic information.

3 [*Note 2*: Modifying any list requires access to the element preceding the first element of interest, but in a `forward_list` there is no constant-time way to access a preceding element. For this reason, `erase_after` and `splice_after` take fully-open ranges, not semi-open ranges. — *end note*]

4 The types `iterator` and `const_iterator` meet the constexpr iterator requirements (24.3.1).

```
namespace std {
  template<class T, class Allocator = allocator<T>>
  class forward_list {
  public:
```

```
// types
using value_type      = T;
using allocator_type  = Allocator;
using pointer         = allocator_traits<Allocator>::pointer;
using const_pointer   = allocator_traits<Allocator>::const_pointer;
using reference       = value_type&;
using const_reference = const value_type&;
using size_type       = implementation-defined; // see 23.2
using difference_type = implementation-defined; // see 23.2
using iterator        = implementation-defined; // see 23.2
using const_iterator  = implementation-defined; // see 23.2

// 23.3.7.2, construct/copy/destroy
constexpr forward_list() : forward_list(Allocator()) { }
constexpr explicit forward_list(const Allocator&);
constexpr explicit forward_list(size_type n, const Allocator& = Allocator());
constexpr forward_list(size_type n, const T& value, const Allocator& = Allocator());
template<class InputIterator>
  constexpr forward_list(InputIterator first, InputIterator last,
                         const Allocator& = Allocator());
template<container-compatible-range<T> R>
  constexpr forward_list(from_range_t, R&& rg, const Allocator& = Allocator());
constexpr forward_list(const forward_list& x);

    constexpr void reverse() noexcept;
  };

  template<class InputIterator, class Allocator = allocator<iter-value-type<InputIterator>>>
    forward_list(InputIterator, InputIterator, Allocator = Allocator())
      -> forward_list<iter-value-type<InputIterator>, Allocator>;

  template<ranges::input_range R, class Allocator = allocator<ranges::range_value_t<R>>>
    forward_list(from_range_t, R&&, Allocator = Allocator())
      -> forward_list<ranges::range_value_t<R>, Allocator>;
}
```

5 An incomplete type `T` may be used when instantiating `forward_list` if the allocator meets the allocator completeness requirements (16.4.4.6.2). `T` shall be complete before any member of the resulting specialization of `forward_list` is referenced.

23.3.7.2 Constructors, copy, and assignment [forward.list.cons]

```
constexpr explicit forward_list(const Allocator&);
```

1 *Effects*: Constructs an empty `forward_list` object using the specified allocator.

2 *Complexity*: Constant.

```
constexpr explicit forward_list(size_type n, const Allocator& = Allocator());
```

3 *Preconditions*: `T` is *Cpp17DefaultInsertable* into `forward_list`.

4 *Effects*: Constructs a `forward_list` object with `n` default-inserted elements using the specified allocator.

5 *Complexity*: Linear in `n`.

```
constexpr forward_list(size_type n, const T& value, const Allocator& = Allocator());
```

6 *Preconditions*: `T` is *Cpp17CopyInsertable* into `forward_list`.

7 *Effects*: Constructs a `forward_list` object with `n` copies of `value` using the specified allocator.

8 *Complexity*: Linear in `n`.

```
template<class InputIterator>
  constexpr forward_list(InputIterator first, InputIterator last, const Allocator& = Allocator());
```

9 *Effects*: Constructs a `forward_list` object equal to the range [`first`, `last`).

10 *Complexity*: Linear in `distance(first, last)`.

```
template<container-compatible-range<T> R>
  constexpr forward_list(from_range_t, R&& rg, const Allocator& = Allocator());
```

11 *Effects*: Constructs a `forward_list` object with the elements of the range `rg`.

12 *Complexity*: Linear in `ranges::distance(rg)`.

23.3.7.3 Iterators [forward.list.iter]

```
constexpr iterator before_begin() noexcept;
constexpr const_iterator before_begin() const noexcept;
constexpr const_iterator cbefore_begin() const noexcept;
```

1 *Effects*: `cbefore_begin()` is equivalent to `const_cast<forward_list const&>(*this).before_begin()`.

2 *Returns*: A non-dereferenceable iterator that, when incremented, is equal to the iterator returned by `begin()`.

3 *Remarks*: `before_begin() == end()` shall equal `false`.

23.3.7.4 Element access [forward.list.access]

```
constexpr reference front();
constexpr const_reference front() const;
```

1 *Returns*: `*begin()`

23.3.7.5 Modifiers [forward.list.modifiers]

1 The member functions in this subclause do not affect the validity of iterators and references when inserting elements, and when erasing elements invalidate iterators and references to the erased elements only. If an exception is thrown by any of these member functions there is no effect on the container. Inserting `n` elements into a `forward_list` is linear in `n`, and the number of calls to the copy or move constructor of `T` is exactly equal to `n`. Erasing `n` elements from a `forward_list` is linear in `n` and the number of calls to the destructor of type `T` is exactly equal to `n`.

```
template<class... Args> constexpr reference emplace_front(Args&&... args);
```

2 *Effects*: Inserts an object of type `value_type` constructed with `value_type(std::forward<Args>(args)...)` at the beginning of the list.

```
constexpr void push_front(const T& x);
constexpr void push_front(T&& x);
```

3 *Effects*: Inserts a copy of `x` at the beginning of the list.

```
template<container-compatible-range<T> R>
  constexpr void prepend_range(R&& rg);
```

4 *Effects*: Inserts a copy of each element of `rg` at the beginning of the list.

[*Note 1*: The order of elements is not reversed. — *end note*]

```
constexpr void pop_front();
```

5 *Effects*: As if by `erase_after(before_begin())`.

```
constexpr iterator insert_after(const_iterator position, const T& x);
```

6 *Preconditions*: `T` is *Cpp17CopyInsertable* into `forward_list`. `position` is `before_begin()` or is a dereferenceable iterator in the range [`begin()`, `end()`).

7 *Effects*: Inserts a copy of `x` after `position`.

8 *Returns*: An iterator pointing to the copy of `x`.

```
constexpr iterator insert_after(const_iterator position, T&& x);
```

9 *Preconditions*: `T` is *Cpp17MoveInsertable* into `forward_list`. `position` is `before_begin()` or is a dereferenceable iterator in the range [`begin()`, `end()`).

10 *Effects*: Inserts a copy of `x` after `position`.

11 *Returns*: An iterator pointing to the copy of `x`.

```
constexpr iterator insert_after(const_iterator position, size_type n, const T& x);
```

12 *Preconditions*: `T` is *Cpp17CopyInsertable* into `forward_list`. `position` is `before_begin()` or is a dereferenceable iterator in the range [`begin()`, `end()`).

13 *Effects*: Inserts `n` copies of `x` after `position`.

14 *Returns*: An iterator pointing to the last inserted copy of `x`, or `position` if `n == 0` is `true`.

```
template<class InputIterator>
  constexpr iterator insert_after(const_iterator position,
                                  InputIterator first, InputIterator last);
```

15 *Preconditions*: `T` is *Cpp17EmplaceConstructible* into `forward_list` from `*first`. `position` is `before_begin()` or is a dereferenceable iterator in the range [`begin()`, `end()`). Neither `first` nor `last` are iterators in `*this`.

16 *Effects*: Inserts copies of elements in [`first`, `last`) after `position`.

17 *Returns*: An iterator pointing to the last inserted element, or `position` if `first == last` is `true`.

```
template<container-compatible-range<T> R>
  constexpr iterator insert_range_after(const_iterator position, R&& rg);
```

18 *Preconditions*: `T` is *Cpp17EmplaceConstructible* into `forward_list` from `*ranges::begin(rg)`. `position` is `before_begin()` or is a dereferenceable iterator in the range [`begin()`, `end()`). `rg` and `*this` do not overlap.

19 *Effects*: Inserts copies of elements in the range `rg` after `position`.

20 *Returns*: An iterator pointing to the last inserted element, or `position` if `rg` is empty.

```
constexpr iterator insert_after(const_iterator position, initializer_list<T> il);
```

21 *Effects*: Equivalent to: `return insert_after(position, il.begin(), il.end());`

```
template<class... Args>
  constexpr iterator emplace_after(const_iterator position, Args&&... args);
```

22 *Preconditions*: `T` is *Cpp17EmplaceConstructible* into `forward_list` from `std::forward<Args>(args)...`. `position` is `before_begin()` or is a dereferenceable iterator in the range [`begin()`, `end()`).

23 *Effects*: Inserts an object of type `value_type` direct-non-list-initialized with `std::forward<Args>(args)...` after `position`.

24 *Returns*: An iterator pointing to the new object.

```
constexpr iterator erase_after(const_iterator position);
```

25 *Preconditions*: The iterator following `position` is dereferenceable.

26 *Effects*: Erases the element pointed to by the iterator following `position`.

27 *Returns*: An iterator pointing to the element following the one that was erased, or `end()` if no such element exists.

28 *Throws*: Nothing.

```
constexpr iterator erase_after(const_iterator position, const_iterator last);
```

29 *Preconditions*: All iterators in the range (`position`, `last`) are dereferenceable.

30 *Effects*: Erases the elements in the range (`position`, `last`).

31 *Returns*: `last`.

32 *Throws*: Nothing.

```
constexpr void resize(size_type sz);
```

33 *Preconditions*: `T` is *Cpp17DefaultInsertable* into `forward_list`.

34 *Effects*: If `sz < distance(begin(), end())`, erases the last `distance(begin(), end()) - sz` elements from the list. Otherwise, inserts `sz - distance(begin(), end())` default-inserted elements at the end of the list.

```
constexpr void resize(size_type sz, const value_type& c);
```

35 *Preconditions*: `T` is *Cpp17CopyInsertable* into `forward_list`.

36 *Effects*: If `sz < distance(begin(), end())`, erases the last `distance(begin(), end()) - sz` elements from the list. Otherwise, inserts `sz - distance(begin(), end())` copies of `c` at the end of the list.

```
constexpr void clear() noexcept;
```

37 *Effects*: Erases all elements in the range [`begin()`, `end()`).

38 *Remarks*: Does not invalidate past-the-end iterators.

23.3.7.6 Operations [forward.list.ops]

1 In this subclause, arguments for a template parameter named `Predicate` or `BinaryPredicate` shall meet the corresponding requirements in 26.2. The semantics of `i + n`, where `i` is an iterator into the list and `n` is an integer, are the same as those of `next(i, n)`. The expression `i - n`, where `i` is an iterator into the list and `n` is an integer, means an iterator `j` such that `j + n == i` is `true`. For `merge` and `sort`, the definitions and requirements in 26.8 apply.

```
constexpr void splice_after(const_iterator position, forward_list& x);
constexpr void splice_after(const_iterator position, forward_list&& x);
```

2 *Preconditions*: `position` is `before_begin()` or is a dereferenceable iterator in the range [`begin()`, `end()`). `get_allocator() == x.get_allocator()` is `true`. `addressof(x) != this` is `true`.

3 *Effects*: Inserts the contents of `x` after `position`, and `x` becomes empty. Pointers and references to the moved elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into `x`.

4 *Throws*: Nothing.

5 *Complexity*: $\mathcal{O}$(`distance(x.begin(), x.end())`)

```
constexpr void splice_after(const_iterator position, forward_list& x, const_iterator i);
constexpr void splice_after(const_iterator position, forward_list&& x, const_iterator i);
```

6 *Preconditions*: `position` is `before_begin()` or is a dereferenceable iterator in the range [`begin()`, `end()`). The iterator following `i` is a dereferenceable iterator in `x`. `get_allocator() == x.get_allocator()` is `true`.

7 *Effects*: Inserts the element following `i` into `*this`, following `position`, and removes it from `x`. The result is unchanged if `position == i` or `position == ++i`. Pointers and references to `*++i` continue to refer to the same element but as a member of `*this`. Iterators to `*++i` continue to refer to the same element, but now behave as iterators into `*this`, not into `x`.

8 *Throws*: Nothing.

9 *Complexity*: $\mathcal{O}(1)$

```
constexpr void splice_after(const_iterator position, forward_list& x,
                            const_iterator first, const_iterator last);
constexpr void splice_after(const_iterator position, forward_list&& x,
                            const_iterator first, const_iterator last);
```

10 *Preconditions*: `position` is `before_begin()` or is a dereferenceable iterator in the range [`begin()`, `end()`). (`first`, `last`) is a valid range in `x`, and all iterators in the range (`first`, `last`) are dereferenceable. `position` is not an iterator in the range (`first`, `last`). `get_allocator() == x.get_allocator()` is `true`.

11 *Effects*: Inserts elements in the range (`first`, `last`) after `position` and removes the elements from `x`. Pointers and references to the moved elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into `x`.

12 *Complexity*: $\mathcal{O}$(`distance(first, last)`)

```
constexpr size_type remove(const T& value);
template<class Predicate> constexpr size_type remove_if(Predicate pred);
```

13 *Effects*: Erases all the elements in the list referred to by a list iterator `i` for which the following conditions hold: `*i == value` (for `remove()`), `pred(*i)` is `true` (for `remove_if()`). Invalidates only the iterators and references to the erased elements.

14 *Returns*: The number of elements erased.

15 *Throws*: Nothing unless an exception is thrown by the equality comparison or the predicate.

16 *Complexity*: Exactly `distance(begin(), end())` applications of the corresponding predicate.

17 *Remarks*: Stable (16.4.6.8).

```
constexpr size_type unique();
template<class BinaryPredicate> constexpr size_type unique(BinaryPredicate binary_pred);
```

18 Let `binary_pred` be `equal_to<>{}` for the first overload.

19 *Preconditions*: `binary_pred` is an equivalence relation.

20 *Effects*: Erases all but the first element from every consecutive group of equivalent elements. That is, for a nonempty list, erases all elements referred to by the iterator `i` in the range [`begin() + 1`, `end()`) for which `binary_pred(*i, *(i - 1))` is `true`. Invalidates only the iterators and references to the erased elements.

21 *Returns*: The number of elements erased.

22 *Throws*: Nothing unless an exception is thrown by the predicate.

23 *Complexity*: If `empty()` is `false`, exactly `distance(begin(), end()) - 1` applications of the corresponding predicate, otherwise no applications of the predicate.

```
constexpr void merge(forward_list& x);
constexpr void merge(forward_list&& x);
template<class Compare> constexpr void merge(forward_list& x, Compare comp);
```

```
template<class Compare> constexpr void merge(forward_list&& x, Compare comp);
```

24 Let `comp` be `less<>` for the first two overloads.

25 *Preconditions*: `*this` and `x` are both sorted with respect to the comparator `comp`, and `get_allocator() == x.get_allocator()` is `true`.

26 *Effects*: If `addressof(x) == this`, there are no effects. Otherwise, merges the two sorted ranges [`begin()`, `end()`) and [`x.begin()`, `x.end()`). The result is a range that is sorted with respect to the comparator `comp`. Pointers and references to the moved elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into `x`.

27 *Complexity*: At most `distance(begin(), end()) + distance(x.begin(), x.end()) - 1` comparisons if `addressof(x) != this`; otherwise, no comparisons are performed.

28 *Remarks*: Stable (16.4.6.8). If `addressof(x) != this`, `x` is empty after the merge. No elements are copied by this operation. If an exception is thrown other than by a comparison, there are no effects.

```
constexpr void sort();
template<class Compare> constexpr void sort(Compare comp);
```

29 *Effects*: Sorts the list according to the `operator<` or the `comp` function object. If an exception is thrown, the order of the elements in `*this` is unspecified. Does not affect the validity of iterators and references.

30 *Complexity*: Approximately $N \log N$ comparisons, where N is `distance(begin(), end())`.

31 *Remarks*: Stable (16.4.6.8).

```
constexpr void reverse() noexcept;
```

32 *Effects*: Reverses the order of the elements in the list. Does not affect the validity of iterators and references.

33 *Complexity*: Linear time.

23.3.7.7 Erasure [forward.list.erasure]

```
template<class T, class Allocator, class U = T>
  constexpr typename forward_list<T, Allocator>::size_type
    erase(forward_list<T, Allocator>& c, const U& value);
```

1 *Effects*: Equivalent to:

```
return erase_if(c, [&](const auto& elem) -> bool { return elem == value; });
```

```
template<class T, class Allocator, class Predicate>
  constexpr typename forward_list<T, Allocator>::size_type
    erase_if(forward_list<T, Allocator>& c, Predicate pred);
```

2 *Effects*: Equivalent to: `return c.remove_if(pred);`

23.3.8 Header <hive> synopsis [hive.syn]

```
#include <initializer_list>     // see 17.11.2
#include <compare>              // see 17.12.1

namespace std {
  struct hive_limits {
    size_t min;
    size_t max;
    constexpr hive_limits(size_t minimum, size_t maximum) noexcept
      : min(minimum), max(maximum) {}
  };

  // 23.3.9, class template hive
  template<class T, class Allocator = allocator<T>> class hive;
```

```
  template<class T, class Allocator>
    void swap(hive<T, Allocator>& x, hive<T, Allocator>& y)
      noexcept(noexcept(x.swap(y)));

  template<class T, class Allocator, class U = T>
    typename hive<T, Allocator>::size_type
      erase(hive<T, Allocator>& c, const U& value);

  template<class T, class Allocator, class Predicate>
    typename hive<T, Allocator>::size_type
      erase_if(hive<T, Allocator>& c, Predicate pred);

  namespace pmr {
    template<class T>
      using hive = std::hive<T, polymorphic_allocator<T>>;
  }
}
```

23.3.9 Class template `hive` [hive]

23.3.9.1 Overview [hive.overview]

1 A `hive` is a type of sequence container that provides constant-time insertion and erasure operations. Storage is automatically managed in multiple memory blocks, referred to as *element blocks*. Insertion (23.3.9.4) position is determined by the container, and insertion may re-use the memory locations of erased elements.

[*Note 1*: Construction and assignment are not considered to involve insertion operations. — *end note*]

2 Element blocks which contain elements are referred to as *active blocks*, those which do not are referred to as *reserved blocks*. Active blocks which become empty of elements are either deallocated or become reserved blocks. Reserved blocks become active blocks when they are used to store elements. A user can create additional reserved blocks by calling `reserve`.

3 Erasures use unspecified techniques of constant time complexity to identify the memory locations of erased elements, which are subsequently skipped during iteration, as opposed to relocating subsequent elements during erasure.

4 Active block capacities have an implementation-defined growth factor (which need not be integral), for example a new active block's capacity could be equal to the summed capacities of the pre-existing active blocks.

5 Limits can be placed on both the minimum and maximum element capacities of element blocks, both by users and implementations.

(5.1) — The minimum limit shall be no larger than the maximum limit.

(5.2) — When limits are not specified by a user during construction, the implementation's default limits are used.

(5.3) — The default limits of an implementation are not guaranteed to be the same as the minimum and maximum possible capacities for an implementation's element blocks.

[*Note 2*: To allow latitude for both implementation-specific and user-directed optimization. — *end note*]

The latter are defined as hard limits. The maximum hard limit shall be no larger than `std::allocator_traits<Allocator>::max_size()`.

(5.4) — If user-specified limits passed to a `hive` constructor or `reshape` are not within hard limits, or if the specified minimum limit is greater than the specified maximum limit, the behavior is erroneous and the effects are implementation-defined.

[*Note 3*: This condition can be checked using `is_within_hard_limits`. — *end note*]

(5.5) — An element block is said to be *within the bounds* of a pair of minimum/maximum limits when its capacity is greater-or-equal-to the minimum limit and less-than-or-equal-to the maximum limit.

6 A `hive` conforms to the requirements for containers (23.2.2.2), with the exception of operators `==` and `!=`. A `hive` also meets the requirements of a reversible container (23.2.2.3), of an allocator-aware container (23.2.2.5), and some of the requirements of a sequence container (23.2.4). Descriptions are provided here only for operations on `hive` that are not described in that table or for operations where there is additional semantic information.

7 The iterators of `hive` meet the *Cpp17BidirectionalIterator* requirements but also model `three_way_comparable<strong_ordering>`.

```
namespace std {
  template<class T, class Allocator = allocator<T>>
  class hive {
  public:
    // types
    using value_type = T;
    using allocator_type = Allocator;
    using pointer = allocator_traits<Allocator>::pointer;
    using const_pointer = allocator_traits<Allocator>::const_pointer;
    using reference = value_type&;
    using const_reference = const value_type&;
    using size_type = implementation-defined;                          // see 23.2
    using difference_type = implementation-defined;                    // see 23.2
    using iterator = implementation-defined;                           // see 23.2
    using const_iterator = implementation-defined;                     // see 23.2
    using reverse_iterator = std::reverse_iterator<iterator>;          // see 23.2
    using const_reverse_iterator = std::reverse_iterator<const_iterator>;   // see 23.2

    // 23.3.9.2, construct/copy/destroy
    constexpr hive() noexcept(noexcept(Allocator())) : hive(Allocator()) {}
    constexpr explicit hive(const Allocator&) noexcept;
    constexpr explicit hive(hive_limits block_limits) : hive(block_limits, Allocator()) {}
    constexpr hive(hive_limits block_limits, const Allocator&);
    explicit hive(size_type n, const Allocator& = Allocator());
    hive(size_type n, hive_limits block_limits, const Allocator& = Allocator());
    hive(size_type n, const T& value, const Allocator& = Allocator());
    hive(size_type n, const T& value, hive_limits block_limits, const Allocator& = Allocator());
    template<class InputIterator>
      hive(InputIterator first, InputIterator last, const Allocator& = Allocator());
    template<class InputIterator>
      hive(InputIterator first, InputIterator last, hive_limits block_limits,
           const Allocator& = Allocator());
    template<container-compatible-range<T> R>
      hive(from_range_t, R&& rg, const Allocator& = Allocator());
    template<container-compatible-range<T> R>
      hive(from_range_t, R&& rg, hive_limits block_limits, const Allocator& = Allocator());
    hive(const hive& x);
    hive(hive&&) noexcept;

}
```

23.3.9.2 Constructors, copy, and assignment [hive.cons]

```
constexpr explicit hive(const Allocator&) noexcept;
```

1 *Effects*: Constructs an empty `hive`, using the specified allocator.

2 *Complexity*: Constant.

```
constexpr hive(hive_limits block_limits, const Allocator&);
```

3 *Effects*: Constructs an empty `hive`, using the specified allocator. Initializes *`current-limits`* with `block_limits`.

4 *Complexity*: Constant.

```
explicit hive(size_type n, const Allocator& = Allocator());
hive(size_type n, hive_limits block_limits, const Allocator& = Allocator());
```

5 *Preconditions*: `T` is *Cpp17DefaultInsertable* into `hive`.

6 *Effects*: Constructs a `hive` with `n` default-inserted elements, using the specified allocator. If the second overload is called, also initializes *`current-limits`* with `block_limits`.

7 *Complexity*: Linear in `n`.

```
hive(size_type n, const T& value, const Allocator& = Allocator());
hive(size_type n, const T& value, hive_limits block_limits, const Allocator& = Allocator());
```

8 *Preconditions*: `T` is *Cpp17CopyInsertable* into `hive`.

9 *Effects*: Constructs a `hive` with `n` copies of `value`, using the specified allocator. If the second overload is called, also initializes *`current-limits`* with `block_limits`.

10 *Complexity*: Linear in `n`.

```
template<class InputIterator>
  hive(InputIterator first, InputIterator last, const Allocator& = Allocator());
template<class InputIterator>
  hive(InputIterator first, InputIterator last, hive_limits block_limits,
       const Allocator& = Allocator());
```

11 *Effects*: Constructs a `hive` equal to the range [`first`, `last`), using the specified allocator. If the second overload is called, also initializes *`current-limits`* with `block_limits`.

12 *Complexity*: Linear in `distance(first, last)`.

```
template<container-compatible-range<T> R>
  hive(from_range_t, R&& rg, const Allocator& = Allocator());
template<container-compatible-range<T> R>
  hive(from_range_t, R&& rg, hive_limits block_limits, const Allocator& = Allocator());
```

13 *Effects*: Constructs a `hive` object equal to the range `rg`, using the specified allocator. If the second overload is called, also initializes *`current-limits`* with `block_limits`.

14 *Complexity*: Linear in `ranges::distance(rg)`.

```
hive(const hive& x);
hive(const hive& x, const type_identity_t<Allocator>& alloc);
```

15 *Preconditions*: `T` is *Cpp17CopyInsertable* into `hive`.

16 *Effects*: Constructs a `hive` object equal to `x`. If the second overload is called, uses `alloc`. Initializes *`current-limits`* with `x.`*`current-limits`*`.`

17 *Complexity*: Linear in `x.size()`.

```
hive(hive&& x) noexcept;
hive(hive&& x, const type_identity_t<Allocator>& alloc);
```

18 *Preconditions*: For the second overload, when `allocator_traits<Allocator>::is_always_equal::value` is `false`, `T` meets the *Cpp17MoveInsertable* requirements.

19 *Effects*: When the first overload is called, or the second overload is called and `alloc == x.get_allocator()` is `true`, *`current-limits`* is set to `x.`*`current-limits`* and each element block is moved from `x` into `*this`. Pointers and references to the elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the elements of `x` will continue to refer to their elements, but they now behave as iterators into `*this`.

If the second overload is called and `alloc == x.get_allocator()` is `false`, each element in `x` is moved into `*this`. References, pointers and iterators referring to the elements of `x`, as well as the past-the-end iterator of `x`, are invalidated.

20 *Postconditions*: `x.empty()` is `true`. The relative order of the elements of `*this` is the same as that of the elements of `x` prior to the call.

21 *Complexity*: If the second overload is called and `alloc == x.get_allocator()` is `false`, linear in `x.size()`. Otherwise constant.

```
hive(initializer_list<T> il, const Allocator& = Allocator());
hive(initializer_list<T> il, hive_limits block_limits, const Allocator& = Allocator());
```

22 *Preconditions*: `T` is *Cpp17CopyInsertable* into `hive`.

23 *Effects*: Constructs a `hive` object equal to `il`, using the specified allocator. If the second overload is called, also initializes *`current-limits`* with `block_limits`.

24 *Complexity*: Linear in `il.size()`.

```
hive& operator=(const hive& x);
```

25 *Preconditions*: `T` is *Cpp17CopyInsertable* into `hive` and *Cpp17CopyAssignable*.

26 *Effects*: All elements in `*this` are either copy-assigned to, or destroyed. All elements in `x` are copied into `*this`, maintaining their relative order.

[*Note 1*: *`current-limits`* is unchanged. — *end note*]

27 *Complexity*: Linear in `size() + x.size()`.

```
hive& operator=(hive&& x)
  noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
           allocator_traits<Allocator>::is_always_equal::value);
```

28 *Preconditions*: When

```
(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
 allocator_traits<Allocator>::is_always_equal::value)
```

is `false`, `T` is *Cpp17MoveInsertable* into `hive` and *Cpp17MoveAssignable*.

29 *Effects*: Each element in `*this` is either move-assigned to, or destroyed. When

```
(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
 get_allocator() == x.get_allocator())
```

is `true`, *`current-limits`* is set to `x.`*`current-limits`* and each element block is moved from `x` into `*this`. Pointers and references to the elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the elements of `x` will continue to refer to their elements, but they now behave as iterators into `*this`, not into `x`.

When

```
(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
 get_allocator() == x.get_allocator())
```

is `false`, each element in `x` is moved into `*this`. References, pointers and iterators referring to the elements of `x`, as well as the past-the-end iterator of `x`, are invalidated.

30 *Postconditions*: `x.empty()` is `true`. The relative order of the elements of `*this` is the same as that of the elements of `x` prior to this call.

31 *Complexity*: Linear in `size()`. If

```
(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
 get_allocator() == x.get_allocator())
```

is `false`, also linear in `x.size()`.

23.3.9.3 Capacity [hive.capacity]

```
size_type capacity() const noexcept;
```

1 *Returns*: The total number of elements that `*this` can hold without requiring allocation of more element blocks.

2 *Complexity*: Constant.

```
void reserve(size_type n);
```

3 *Effects*: If `n <= capacity()` is `true`, there are no effects. Otherwise increases `capacity()` by allocating reserved blocks.

4 *Postconditions*: `capacity() >= n` is `true`.

5 *Throws*: `length_error` if satisfying the postcondition would cause `capacity()` to exceed `max_size()`, as well as any exceptions thrown by the allocator.

6 *Complexity*: Linear in the number of reserved blocks allocated.

7 *Remarks*: All references, pointers, and iterators referring to elements in `*this`, as well as the past-the-end iterator, remain valid.

```
void shrink_to_fit();
```

8 *Preconditions*: `T` is *Cpp17MoveInsertable* into `hive`.

9 *Effects*: `shrink_to_fit` is a non-binding request to reduce `capacity()` to be closer to `size()`.

[*Note 1*: The request is non-binding to allow latitude for implementation-specific optimizations. — *end note*]

It does not increase `capacity()`, but may reduce `capacity()`. It may reallocate elements. If `capacity()` is already equal to `size()`, there are no effects. If an exception is thrown during allocation of a new element block, `capacity()` may be reduced and reallocation may occur. Otherwise if an exception is thrown, the effects are unspecified.

10 *Complexity*: If reallocation happens, linear in the size of the sequence.

11 *Remarks*: If reallocation happens, the order of the elements in `*this` may change and all references, pointers, and iterators referring to the elements in `*this`, as well as the past-the-end iterator, are invalidated.

```
void trim_capacity() noexcept;
void trim_capacity(size_type n) noexcept;
```

12 *Effects*: For the first overload, all reserved blocks are deallocated, and `capacity()` is reduced accordingly. For the second overload, if `n >= capacity()` is `true`, there are no effects; otherwise, `capacity()` is reduced to no less than `n`.

13 *Complexity*: Linear in the number of reserved blocks deallocated.

14 *Remarks*: All references, pointers, and iterators referring to elements in `*this`, as well as the past-the-end iterator, remain valid.

```
constexpr hive_limits block_capacity_limits() const noexcept;
```

15 *Returns*: *`current-limits`*.

16 *Complexity*: Constant.

```
static constexpr hive_limits block_capacity_default_limits() noexcept;
```

17 *Returns*: A `hive_limits` struct with the `min` and `max` members set to the implementation's default limits.

18 *Complexity*: Constant.

```
static constexpr hive_limits block_capacity_hard_limits() noexcept;
```

19 *Returns*: A `hive_limits` struct with the `min` and `max` members set to the implementation's hard limits.

20 *Complexity*: Constant.

```
static constexpr bool is_within_hard_limits(hive_limits lim) noexcept;
```

21 Let `hl` be `block_capacity_hard_limits()`.

22 *Returns*: `hl.min <= lim.min && lim.min <= lim.max && lim.max <= hl.max`.

```
void reshape(hive_limits block_limits);
```

23 *Preconditions*: `T` is *Cpp17MoveInsertable* into `hive`.

24 *Effects*: For any active blocks not within the bounds of `block_limits`, the elements within those active blocks are reallocated to new or existing element blocks which are within the bounds. Any element blocks not within the bounds of `block_limits` are deallocated. If an exception is thrown during allocation of a new element block, `capacity()` may be reduced, reallocation may occur, and *`current-limits`* may be assigned a value other than `block_limits`. Otherwise `block_limits` is assigned to *`current-limits`*. If any other exception is thrown the effects are unspecified.

25 *Postconditions*: `size()` is unchanged.

26 *Complexity*: Linear in the number of element blocks in `*this`. If reallocation happens, also linear in the number of elements reallocated.

27 *Remarks*: This operation may change `capacity()`. If reallocation happens, the order of the elements in `*this` may change. Reallocation invalidates all references, pointers, and iterators referring to the elements in `*this`, as well as the past-the-end iterator.

[*Note 2*: If no reallocation happens, they remain valid. — *end note*]

23.3.9.4 Modifiers [hive.modifiers]

```
template<class... Args> iterator emplace(Args&&... args);
template<class... Args> iterator emplace_hint(const_iterator hint, Args&&... args);
```

1 *Preconditions*: `T` is *Cpp17EmplaceConstructible* into `hive` from `args`.

2 *Effects*: Inserts an object of type `T` constructed with `std::forward<Args>(args)...`. The `hint` parameter is ignored. If an exception is thrown, there are no effects.

[*Note 1*: `args` can directly or indirectly refer to a value in `*this`. — *end note*]

3 *Returns*: An iterator that points to the new element.

4 *Complexity*: Constant. Exactly one object of type `T` is constructed.

5 *Remarks*: Invalidates the past-the-end iterator.

```
iterator insert(const T& x);
iterator insert(const_iterator hint, const T& x);
iterator insert(T&& x);
iterator insert(const_iterator hint, T&& x);
```

6 *Effects*: Equivalent to: `return emplace(std::forward<decltype(x)>(x));`

[*Note 2*: The `hint` parameter is ignored. — *end note*]

```
void insert(initializer_list<T> rg);
template<container-compatible-range<T> R>
  void insert_range(R&& rg);
```

7 *Preconditions*: `T` is *Cpp17EmplaceInsertable* into `hive` from `*ranges::begin(rg)`. `rg` and `*this` do not overlap.

8 *Effects*: Inserts copies of elements in `rg`. Each iterator in the range `rg` is dereferenced exactly once.

9 *Complexity*: Linear in the number of elements inserted. Exactly one object of type `T` is constructed for each element inserted.

10 *Remarks*: If an element is inserted, invalidates the past-the-end iterator.

```
void insert(size_type n, const T& x);
```

11 *Preconditions*: `T` is *Cpp17CopyInsertable* into `hive`.

12 *Effects*: Inserts `n` copies of `x`.

13 *Complexity*: Linear in `n`. Exactly one object of type `T` is constructed for each element inserted.

14 *Remarks*: If an element is inserted, invalidates the past-the-end iterator.

```
template<class InputIterator>
  void insert(InputIterator first, InputIterator last);
```

15 *Effects*: Equivalent to `insert_range(ranges::subrange(first, last))`.

```
iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
```

16 *Complexity*: Linear in the number of elements erased. Additionally, if any active blocks become empty of elements as a result of the function call, at worst linear in the number of element blocks.

17 *Remarks*: Invalidates references, pointers and iterators referring to the erased elements. An erase operation that erases the last element in `*this` also invalidates the past-the-end iterator.

```
void swap(hive& x)
  noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
           allocator_traits<Allocator>::is_always_equal::value);
```

18 *Effects*: Exchanges the contents, `capacity()`, and *`current-limits`* of `*this` with that of `x`.

19 *Complexity*: Constant.

23.3.9.5 Operations [hive.operations]

1 In this subclause, arguments for a template parameter named `Predicate` or `BinaryPredicate` shall meet the corresponding requirements in 26.2. The semantics of `i + n` and `i - n`, where `i` is an iterator into the `hive` and `n` is an integer, are the same as those of `next(i, n)` and `prev(i, n)`, respectively. For `sort`, the definitions and requirements in 26.8 apply.

```
void splice(hive& x);
void splice(hive&& x);
```

2 *Preconditions*: `get_allocator() == x.get_allocator()` is `true`.

3 *Effects*: If `addressof(x) == this` is `true`, the behavior is erroneous and there are no effects. If an exception is thrown, there are no effects. Otherwise, inserts the contents of `x` into `*this` and `x` becomes empty. Pointers and references to the moved elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the moved elements continue to refer to their elements, but they now behave as iterators into `*this`, not into `x`.

4 *Throws*: `length_error` if any of `x`'s active blocks are not within the bounds of *`current-limits`*, as well as any exceptions thrown by the allocator.

5 *Complexity*: Linear in the sum of all element blocks in `x` plus all element blocks in `*this`.

6 *Remarks*: Reserved blocks in `x` are not transferred into `*this`. If `addressof(x) == this` is `false`, invalidates the past-the-end iterator for both `x` and `*this`.

```
template<class BinaryPredicate = equal_to<T>>
  size_type unique(BinaryPredicate binary_pred = BinaryPredicate());
```

7 *Preconditions*: `binary_pred` is an equivalence relation.

8 *Effects*: Erases all but the first element from every consecutive group of equivalent elements. That is, for a nonempty `hive`, erases all elements referred to by the iterator `i` in the range [`begin() + 1`, `end()`) for which `binary_pred(*i, *(i - 1))` is `true`.

9 *Returns*: The number of elements erased.

10 *Throws*: Nothing unless an exception is thrown by the predicate.

11 *Complexity*: If `empty()` is `false`, exactly `size() - 1` applications of the corresponding predicate, otherwise no applications of the predicate.

12 *Remarks*: Invalidates references, pointers, and iterators referring to the erased elements. If the last element in `*this` is erased, also invalidates the past-the-end iterator.

```
template<class Compare = less<T>>
  void sort(Compare comp = Compare());
```

13 *Preconditions*: `T` is *Cpp17MoveInsertable* into `hive`, *Cpp17MoveAssignable*, and *Cpp17Swappable*.

14 *Effects*: Sorts `*this` according to the `comp` function object. If an exception is thrown, the order of the elements in `*this` is unspecified.

15 *Complexity*: $\mathcal{O}(N \log N)$ comparisons, where N is `size()`.

16 *Remarks*: May allocate. References, pointers, and iterators referring to elements in `*this`, as well as the past-the-end iterator, may be invalidated.

[*Note 1*: Not required to be stable (16.4.6.8). — *end note*]

```
iterator get_iterator(const_pointer p) noexcept;
const_iterator get_iterator(const_pointer p) const noexcept;
```

17 *Preconditions*: `p` points to an element in `*this`.

18 *Returns*: An `iterator` or `const_iterator` pointing to the same element as `p`.

19 *Complexity*: Linear in the number of active blocks in `*this`.

23.3.9.6 Erasure [hive.erasure]

```
template<class T, class Allocator, class U = T>
  typename hive<T, Allocator>::size_type
    erase(hive<T, Allocator>& c, const U& value);
```

1 *Effects*: Equivalent to:

```
return erase_if(c, [&](const auto& elem) -> bool { return elem == value; });
```

```
template<class T, class Allocator, class Predicate>
  typename hive<T, Allocator>::size_type
    erase_if(hive<T, Allocator>& c, Predicate pred);
```

2 *Effects*: Equivalent to:

```
auto original_size = c.size();
for (auto i = c.begin(); i != c.end(); ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
}
return original_size - c.size();
```

23.3.10 Header <list> synopsis [list.syn]

```
#include <compare>             // see 17.12.1
#include <initializer_list>    // see 17.11.2

namespace std {
  // 23.3.11, class template list
  template<class T, class Allocator = allocator<T>> class list;

  template<class T, class Allocator>
    constexpr bool operator==(const list<T, Allocator>& x, const list<T, Allocator>& y);
  template<class T, class Allocator>
    constexpr synth-three-way-result<T>
      operator<=>(const list<T, Allocator>& x, const list<T, Allocator>& y);
```

```
  template<class T, class Allocator>
    constexpr void swap(list<T, Allocator>& x, list<T, Allocator>& y)
      noexcept(noexcept(x.swap(y)));

  // 23.3.11.6, erasure
  template<class T, class Allocator, class U = T>
    constexpr typename list<T, Allocator>::size_type
      erase(list<T, Allocator>& c, const U& value);
  template<class T, class Allocator, class Predicate>
    constexpr typename list<T, Allocator>::size_type
      erase_if(list<T, Allocator>& c, Predicate pred);

  namespace pmr {
    template<class T>
      using list = std::list<T, polymorphic_allocator<T>>;
  }
}
```

23.3.11 Class template `list` [list]

23.3.11.1 Overview [list.overview]

1 A `list` is a sequence container that supports bidirectional iterators and allows constant time insert and erase operations anywhere within the sequence, with storage management handled automatically. Unlike vectors (23.3.13) and deques (23.3.5), fast random access to list elements is not supported, but many algorithms only need sequential access anyway.

2 A `list` meets all of the requirements of a container (23.2.2.2), of a reversible container (23.2.2.3), of an allocator-aware container (23.2.2.5), and of a sequence container, including most of the optional sequence container requirements (23.2.4). The exceptions are the `operator[]` and `at` member functions, which are not provided.[175] Descriptions are provided here only for operations on `list` that are not described in one of these tables or for operations where there is additional semantic information.

3 The types `iterator` and `const_iterator` meet the constexpr iterator requirements (24.3.1).

```
namespace std {
  template<class T, class Allocator = allocator<T>>
  class list {
  public:
    // types
    using value_type             = T;
    using allocator_type         = Allocator;
    using pointer                = allocator_traits<Allocator>::pointer;
    using const_pointer          = allocator_traits<Allocator>::const_pointer;
    using reference              = value_type&;
    using const_reference        = const value_type&;
    using size_type              = implementation-defined; // see 23.2
    using difference_type        = implementation-defined; // see 23.2
    using iterator               = implementation-defined; // see 23.2
    using const_iterator         = implementation-defined; // see 23.2
    using reverse_iterator       = std::reverse_iterator<iterator>;
    using const_reverse_iterator = std::reverse_iterator<const_iterator>;

    // 23.3.11.2, construct/copy/destroy
    constexpr list() : list(Allocator()) { }
    constexpr explicit list(const Allocator&);
    constexpr explicit list(size_type n, const Allocator& = Allocator());
    constexpr list(size_type n, const T& value, const Allocator& = Allocator());
    template<class InputIterator>
      constexpr list(InputIterator first, InputIterator last, const Allocator& = Allocator());
    template<container-compatible-range<T> R>
      constexpr list(from_range_t, R&& rg, const Allocator& = Allocator());
    constexpr list(const list& x);
    constexpr list(list&& x);
```

175) These member functions are only provided by containers whose iterators are random access iterators.

```
constexpr list(const list&, const type_identity_t<Allocator>&);
constexpr list(list&&, const type_identity_t<Allocator>&);
constexpr list(initializer_list<T>, const Allocator& = Allocator());
constexpr ~list();
constexpr list& operator=(const list& x);
constexpr list& operator=(list&& x)
  noexcept(allocator_traits<Allocator>::is_always_equal::value);
constexpr list& operator=(initializer_list<T>);

  template<class InputIterator, class Allocator = allocator<iter-value-type<InputIterator>>>
    list(InputIterator, InputIterator, Allocator = Allocator())
      -> list<iter-value-type<InputIterator>, Allocator>;

  template<ranges::input_range R, class Allocator = allocator<ranges::range_value_t<R>>>
    list(from_range_t, R&&, Allocator = Allocator())
      -> list<ranges::range_value_t<R>, Allocator>;
}
```

4 An incomplete type `T` may be used when instantiating `list` if the allocator meets the allocator completeness requirements (16.4.4.6.2). `T` shall be complete before any member of the resulting specialization of `list` is referenced.

23.3.11.2 Constructors, copy, and assignment [list.cons]

```
constexpr explicit list(const Allocator&);
```

1 *Effects*: Constructs an empty `list`, using the specified allocator.

2 *Complexity*: Constant.

```
constexpr explicit list(size_type n, const Allocator& = Allocator());
```

3 *Preconditions*: `T` is *Cpp17DefaultInsertable* into `list`.

4 *Effects*: Constructs a `list` with `n` default-inserted elements using the specified allocator.

5 *Complexity*: Linear in `n`.

```
constexpr list(size_type n, const T& value, const Allocator& = Allocator());
```

6 *Preconditions*: `T` is *Cpp17CopyInsertable* into `list`.

7 *Effects*: Constructs a `list` with `n` copies of `value`, using the specified allocator.

8 *Complexity*: Linear in `n`.

```
template<class InputIterator>
  constexpr list(InputIterator first, InputIterator last, const Allocator& = Allocator());
```

9 *Effects*: Constructs a `list` equal to the range [`first`, `last`).

10 *Complexity*: Linear in `distance(first, last)`.

```
template<container-compatible-range<T> R>
  constexpr list(from_range_t, R&& rg, const Allocator& = Allocator());
```

11 *Effects*: Constructs a `list` object with the elements of the range `rg`.

12 *Complexity*: Linear in `ranges::distance(rg)`.

23.3.11.3 Capacity [list.capacity]

```
constexpr void resize(size_type sz);
```

1 *Preconditions*: `T` is *Cpp17DefaultInsertable* into `list`.

2 *Effects*: If `size() < sz`, appends `sz - size()` default-inserted elements to the sequence. If `sz <= size()`, equivalent to:

```
list<T>::iterator it = begin();
advance(it, sz);
erase(it, end());
```

```
constexpr void resize(size_type sz, const T& c);
```

3 *Preconditions*: `T` is *Cpp17CopyInsertable* into `list`.

4 *Effects*: As if by:

```
if (sz > size())
  insert(end(), sz-size(), c);
else if (sz < size()) {
  iterator i = begin();
  advance(i, sz);
  erase(i, end());
}
else
  ;                 // do nothing
```

23.3.11.4 Modifiers [list.modifiers]

```
constexpr iterator insert(const_iterator position, const T& x);
constexpr iterator insert(const_iterator position, T&& x);
constexpr iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
  constexpr iterator insert(const_iterator position,
                            InputIterator first, InputIterator last);
template<container-compatible-range<T> R>
  constexpr iterator insert_range(const_iterator position, R&& rg);
constexpr iterator insert(const_iterator position, initializer_list<T>);

template<class... Args> constexpr reference emplace_front(Args&&... args);
template<class... Args> constexpr reference emplace_back(Args&&... args);
template<class... Args> constexpr iterator emplace(const_iterator position, Args&&... args);
constexpr void push_front(const T& x);
constexpr void push_front(T&& x);
template<container-compatible-range<T> R>
  constexpr void prepend_range(R&& rg);
```

```
constexpr void push_back(const T& x);
constexpr void push_back(T&& x);
template<container-compatible-range<T> R>
  constexpr void append_range(R&& rg);
```

1 *Complexity*: Insertion of a single element into a list takes constant time and exactly one call to a constructor of `T`. Insertion of multiple elements into a list is linear in the number of elements inserted, and the number of calls to the copy constructor or move constructor of `T` is exactly equal to the number of elements inserted.

2 *Remarks*: Does not affect the validity of iterators and references. If an exception is thrown, there are no effects.

```
constexpr iterator erase(const_iterator position);
constexpr iterator erase(const_iterator first, const_iterator last);
constexpr void pop_front();
constexpr void pop_back();
constexpr void clear() noexcept;
```

3 *Effects*: Invalidates only the iterators and references to the erased elements.

4 *Throws*: Nothing.

5 *Complexity*: Erasing a single element is a constant time operation with a single call to the destructor of `T`. Erasing a range in a list is linear time in the size of the range and the number of calls to the destructor of type `T` is exactly equal to the size of the range.

23.3.11.5 Operations [list.ops]

1 Since lists allow fast insertion and erasing from the middle of a list, certain operations are provided specifically for them.[176] In this subclause, arguments for a template parameter named `Predicate` or `BinaryPredicate` shall meet the corresponding requirements in 26.2. The semantics of `i + n` and `i - n`, where `i` is an iterator into the list and `n` is an integer, are the same as those of `next(i, n)` and `prev(i, n)`, respectively. For `merge` and `sort`, the definitions and requirements in 26.8 apply.

2 `list` provides three splice operations that destructively move elements from one list to another. The behavior of splice operations is undefined if `get_allocator() != x.get_allocator()`.

```
constexpr void splice(const_iterator position, list& x);
constexpr void splice(const_iterator position, list&& x);
```

3 *Preconditions*: `addressof(x) != this` is `true`.

4 *Effects*: Inserts the contents of `x` before `position` and `x` becomes empty. Pointers and references to the moved elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into `x`.

5 *Throws*: Nothing.

6 *Complexity*: Constant time.

```
constexpr void splice(const_iterator position, list& x, const_iterator i);
constexpr void splice(const_iterator position, list&& x, const_iterator i);
```

7 *Preconditions*: `i` is a valid dereferenceable iterator of `x`.

8 *Effects*: Inserts an element pointed to by `i` from list `x` before `position` and removes the element from `x`. The result is unchanged if `position == i` or `position == ++i`. Pointers and references to `*i` continue to refer to this same element but as a member of `*this`. Iterators to `*i` (including `i` itself) continue to refer to the same element, but now behave as iterators into `*this`, not into `x`.

9 *Throws*: Nothing.

10 *Complexity*: Constant time.

```
constexpr void splice(const_iterator position, list& x,
                      const_iterator first, const_iterator last);
```

176) As specified in 16.4.4.6, the requirements in this Clause apply only to lists whose allocators compare equal.

```
constexpr void splice(const_iterator position, list&& x,
                      const_iterator first, const_iterator last);
```

11 *Preconditions*: [`first`, `last`) is a valid range in `x`. `position` is not an iterator in the range [`first`, `last`).

12 *Effects*: Inserts elements in the range [`first`, `last`) before `position` and removes the elements from `x`. Pointers and references to the moved elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into `x`.

13 *Throws*: Nothing.

14 *Complexity*: Constant time if `addressof(x) == this`; otherwise, linear time.

```
constexpr size_type remove(const T& value);
template<class Predicate> constexpr size_type remove_if(Predicate pred);
```

15 *Effects*: Erases all the elements in the list referred to by a list iterator `i` for which the following conditions hold: `*i == value`, `pred(*i) != false`. Invalidates only the iterators and references to the erased elements.

16 *Returns*: The number of elements erased.

17 *Throws*: Nothing unless an exception is thrown by `*i == value` or `pred(*i) != false`.

18 *Complexity*: Exactly `size()` applications of the corresponding predicate.

19 *Remarks*: Stable (16.4.6.8).

```
constexpr size_type unique();
template<class BinaryPredicate> constexpr size_type unique(BinaryPredicate binary_pred);
```

20 Let `binary_pred` be `equal_to<>{}` for the first overload.

21 *Preconditions*: `binary_pred` is an equivalence relation.

22 *Effects*: Erases all but the first element from every consecutive group of equivalent elements. That is, for a nonempty list, erases all elements referred to by the iterator `i` in the range [`begin() + 1`, `end()`) for which `binary_pred(*i, *(i - 1))` is `true`. Invalidates only the iterators and references to the erased elements.

23 *Returns*: The number of elements erased.

24 *Throws*: Nothing unless an exception is thrown by the predicate.

25 *Complexity*: If `empty()` is `false`, exactly `size() - 1` applications of the corresponding predicate, otherwise no applications of the predicate.

```
constexpr void merge(list& x);
constexpr void merge(list&& x);
template<class Compare> constexpr void merge(list& x, Compare comp);
template<class Compare> constexpr void merge(list&& x, Compare comp);
```

26 Let `comp` be `less<>` for the first two overloads.

27 *Preconditions*: `*this` and `x` are both sorted with respect to the comparator `comp`, and `get_allocator() == x.get_allocator()` is `true`.

28 *Effects*: If `addressof(x) == this`, there are no effects. Otherwise, merges the two sorted ranges [`begin()`, `end()`) and [`x.begin()`, `x.end()`). The result is a range that is sorted with respect to the comparator `comp`. Pointers and references to the moved elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into `x`.

29 *Complexity*: At most `size() + x.size() - 1` comparisons if `addressof(x) != this`; otherwise, no comparisons are performed.

30 *Remarks*: Stable (16.4.6.8). If `addressof(x) != this`, `x` is empty after the merge. No elements are copied by this operation. If an exception is thrown other than by a comparison, there are no effects.

```
constexpr void reverse() noexcept;
```

31 *Effects*: Reverses the order of the elements in the list. Does not affect the validity of iterators and references.

32 *Complexity*: Linear time.

```
void sort();
template<class Compare> void sort(Compare comp);
```

33 *Effects*: Sorts the list according to the `operator<` or a `Compare` function object. If an exception is thrown, the order of the elements in `*this` is unspecified. Does not affect the validity of iterators and references.

34 *Complexity*: Approximately $N \log N$ comparisons, where N is `size()`.

35 *Remarks*: Stable (16.4.6.8).

23.3.11.6 Erasure [list.erasure]

```
template<class T, class Allocator, class U = T>
  typename list<T, Allocator>::size_type
    constexpr erase(list<T, Allocator>& c, const U& value);
```

1 *Effects*: Equivalent to:

```
return erase_if(c, [&](const auto& elem) -> bool { return elem == value; });
```

```
template<class T, class Allocator, class Predicate>
  typename list<T, Allocator>::size_type
    constexpr erase_if(list<T, Allocator>& c, Predicate pred);
```

2 *Effects*: Equivalent to: `return c.remove_if(pred);`

23.3.12 Header <vector> synopsis [vector.syn]

```
#include <compare>              // see 17.12.1

}
```

23.3.13 Class template `vector` [vector]

23.3.13.1 Overview [vector.overview]

1 A `vector` is a sequence container that supports (amortized) constant time insert and erase operations at the end; insert and erase in the middle take linear time. Storage management is handled automatically, though hints can be given to improve efficiency.

2 A `vector` meets all of the requirements of a container (23.2.2.2), of a reversible container (23.2.2.3), of an allocator-aware container (23.2.2.5), of a sequence container, including most of the optional sequence container requirements (23.2.4), and, for an element type other than `bool`, of a contiguous container (23.2.2.2). The exceptions are the `push_front`, `prepend_range`, `pop_front`, and `emplace_front` member functions, which are not provided. Descriptions are provided here only for operations on `vector` that are not described in one of these tables or for operations where there is additional semantic information.

3 The types `iterator` and `const_iterator` meet the constexpr iterator requirements (24.3.1).

```
namespace std {
  template<class T, class Allocator = allocator<T>>
  class vector {
  public:
    // types
    using value_type             = T;
    using allocator_type         = Allocator;
    using pointer                = allocator_traits<Allocator>::pointer;
    using const_pointer          = allocator_traits<Allocator>::const_pointer;
    using reference              = value_type&;
    using const_reference        = const value_type&;
    using size_type              = implementation-defined; // see 23.2
    using difference_type        = implementation-defined; // see 23.2
    using iterator               = implementation-defined; // see 23.2
    using const_iterator         = implementation-defined; // see 23.2
    using reverse_iterator       = std::reverse_iterator<iterator>;
    using const_reverse_iterator = std::reverse_iterator<const_iterator>;

    // 23.3.13.2, construct/copy/destroy
    constexpr vector() noexcept(noexcept(Allocator())) : vector(Allocator()) { }
    constexpr explicit vector(const Allocator&) noexcept;
    constexpr explicit vector(size_type n, const Allocator& = Allocator());
    constexpr vector(size_type n, const T& value, const Allocator& = Allocator());
    template<class InputIterator>
      constexpr vector(InputIterator first, InputIterator last, const Allocator& = Allocator());
    template<container-compatible-range<T> R>

  constexpr void append_range(R&& rg);
constexpr void pop_back();

template<class... Args> constexpr iterator emplace(const_iterator position, Args&&... args);
constexpr iterator insert(const_iterator position, const T& x);
constexpr iterator insert(const_iterator position, T&& x);
constexpr iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
  constexpr iterator insert(const_iterator position,
                            InputIterator first, InputIterator last);
template<container-compatible-range<T> R>
  constexpr iterator insert_range(const_iterator position, R&& rg);
constexpr iterator insert(const_iterator position, initializer_list<T> il);
constexpr iterator erase(const_iterator position);
```

```
    constexpr iterator erase(const_iterator first, const_iterator last);
    constexpr void     swap(vector&)
      noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
               allocator_traits<Allocator>::is_always_equal::value);
    constexpr void     clear() noexcept;
  };

  template<class InputIterator, class Allocator = allocator<iter-value-type<InputIterator>>>
    vector(InputIterator, InputIterator, Allocator = Allocator())
      -> vector<iter-value-type<InputIterator>, Allocator>;

  template<ranges::input_range R, class Allocator = allocator<ranges::range_value_t<R>>>
    vector(from_range_t, R&&, Allocator = Allocator())
      -> vector<ranges::range_value_t<R>, Allocator>;
}
```

4 An incomplete type `T` may be used when instantiating `vector` if the allocator meets the allocator completeness requirements (16.4.4.6.2). `T` shall be complete before any member of the resulting specialization of `vector` is referenced.

23.3.13.2 Constructors [vector.cons]

```
constexpr explicit vector(const Allocator&) noexcept;
```

1 *Effects*: Constructs an empty `vector`, using the specified allocator.

2 *Complexity*: Constant.

```
constexpr explicit vector(size_type n, const Allocator& = Allocator());
```

3 *Preconditions*: `T` is *Cpp17DefaultInsertable* into `vector`.

4 *Effects*: Constructs a `vector` with `n` default-inserted elements using the specified allocator.

5 *Complexity*: Linear in `n`.

```
constexpr vector(size_type n, const T& value,
                 const Allocator& = Allocator());
```

6 *Preconditions*: `T` is *Cpp17CopyInsertable* into `vector`.

7 *Effects*: Constructs a `vector` with `n` copies of `value`, using the specified allocator.

8 *Complexity*: Linear in `n`.

```
template<class InputIterator>
  constexpr vector(InputIterator first, InputIterator last,
                   const Allocator& = Allocator());
```

9 *Effects*: Constructs a `vector` equal to the range [`first`, `last`), using the specified allocator.

10 *Complexity*: Makes only N calls to the copy constructor of `T` (where N is the distance between `first` and `last`) and no reallocations if `InputIterator` meets the *Cpp17ForwardIterator* requirements. It makes order N calls to the copy constructor of `T` and order $\log N$ reallocations if they are just input iterators.

```
template<container-compatible-range<T> R>
  constexpr vector(from_range_t, R&& rg, const Allocator& = Allocator());
```

11 *Effects*: Constructs a `vector` object with the elements of the range `rg`, using the specified allocator.

12 *Complexity*: Initializes exactly N elements from the results of dereferencing successive iterators of `rg`, where N is `ranges::distance(rg)`.

13 Performs no reallocations if:

(13.1) — `R` models `ranges::approximately_sized_range`, and `ranges::distance(rg) <= ranges::reserve_hint(rg)` is `true`, or

(13.2) — `R` models `ranges::forward_range` and `R` does not model `ranges::approximately_sized_range`.

Otherwise, performs order $\log N$ reallocations and order N calls to the copy or move constructor of `T`.

23.3.13.3 Capacity [vector.capacity]

```
constexpr size_type capacity() const noexcept;
```

1 *Returns*: The total number of elements that the vector can hold without requiring reallocation.

2 *Complexity*: Constant time.

```
constexpr void reserve(size_type n);
```

3 *Preconditions*: `T` is *Cpp17MoveInsertable* into `vector`.

4 *Effects*: A directive that informs a `vector` of a planned change in size, so that it can manage the storage allocation accordingly. After `reserve()`, `capacity()` is greater or equal to the argument of `reserve` if reallocation happens; and equal to the previous value of `capacity()` otherwise. Reallocation happens at this point if and only if the current capacity is less than the argument of `reserve()`. If an exception is thrown other than by the move constructor of a non-*Cpp17CopyInsertable* type, there are no effects.

5 *Throws*: `length_error` if `n > max_size()`.[177]

6 *Complexity*: Linear in the size of the sequence.

7 *Remarks*: The size of the sequence is not changed. Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator.

[*Note 1*: If no reallocation happens, they remain valid. — *end note*]

No reallocation shall take place during insertions that happen after a call to `reserve()` until an insertion would make the size of the vector greater than the value of `capacity()`.

```
constexpr void shrink_to_fit();
```

8 *Preconditions*: `T` is *Cpp17MoveInsertable* into `vector`.

9 *Effects*: `shrink_to_fit` is a non-binding request to reduce `capacity()` to `size()`.

[*Note 2*: The request is non-binding to allow latitude for implementation-specific optimizations. — *end note*]

It does not increase `capacity()`, but may reduce `capacity()` by causing reallocation. If an exception is thrown other than by the move constructor of a non-*Cpp17CopyInsertable* `T`, there are no effects.

10 *Complexity*: If reallocation happens, linear in the size of the sequence.

11 *Remarks*: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence as well as the past-the-end iterator.

[*Note 3*: If no reallocation happens, they remain valid. — *end note*]

```
constexpr void swap(vector& x)
  noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
           allocator_traits<Allocator>::is_always_equal::value);
```

12 *Effects*: Exchanges the contents and `capacity()` of `*this` with that of `x`.

13 *Complexity*: Constant time.

```
constexpr void resize(size_type sz);
```

14 *Preconditions*: `T` is *Cpp17MoveInsertable* and *Cpp17DefaultInsertable* into `vector`.

15 *Effects*: If `sz < size()`, erases the last `size() - sz` elements from the sequence. Otherwise, appends `sz - size()` default-inserted elements to the sequence.

16 *Remarks*: If an exception is thrown other than by the move constructor of a non-*Cpp17CopyInsertable* `T`, there are no effects.

```
constexpr void resize(size_type sz, const T& c);
```

17 *Preconditions*: `T` is *Cpp17CopyInsertable* into `vector`.

18 *Effects*: If `sz < size()`, erases the last `size() - sz` elements from the sequence. Otherwise, appends `sz - size()` copies of `c` to the sequence.

19 *Remarks*: If an exception is thrown, there are no effects.

177) `reserve()` uses `Allocator::allocate()` which can throw an appropriate exception.

23.3.13.4 Data [vector.data]

```
constexpr T*       data() noexcept;
constexpr const T* data() const noexcept;
```

1 *Returns*: A pointer such that [`data()`, `data() + size()`) is a valid range. For a non-empty vector, `data() == addressof(front())` is `true`.

2 *Complexity*: Constant time.

23.3.13.5 Modifiers [vector.modifiers]

```
constexpr iterator insert(const_iterator position, const T& x);
constexpr iterator insert(const_iterator position, T&& x);
constexpr iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
  constexpr iterator insert(const_iterator position, InputIterator first, InputIterator last);
template<container-compatible-range<T> R>
  constexpr iterator insert_range(const_iterator position, R&& rg);
constexpr iterator insert(const_iterator position, initializer_list<T>);

template<class... Args> constexpr reference emplace_back(Args&&... args);
template<class... Args> constexpr iterator emplace(const_iterator position, Args&&... args);
constexpr void push_back(const T& x);
constexpr void push_back(T&& x);
template<container-compatible-range<T> R>
  constexpr void append_range(R&& rg);
```

1 *Complexity*: If reallocation happens, linear in the number of elements of the resulting vector; otherwise, linear in the number of elements inserted plus the distance to the end of the vector.

2 *Remarks*: Causes reallocation if the new size is greater than the old capacity. Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator. If no reallocation happens, then references, pointers, and iterators before the insertion point remain valid but those at or after the insertion point, including the past-the-end iterator, are invalidated. If an exception is thrown other than by the copy constructor, move constructor, assignment operator, or move assignment operator of `T` or by any `InputIterator` operation, there are no effects. If an exception is thrown while inserting a single element at the end and `T` is *Cpp17CopyInsertable* or `is_nothrow_move_constructible_v<T>` is `true`, there are no effects. Otherwise, if an exception is thrown by the move constructor of a non-*Cpp17CopyInsertable* `T`, the effects are unspecified.

3 For the declarations taking a range `R`, performs at most one reallocation if:

(3.1) — `R` models `ranges::approximately_sized_range` and `ranges::distance(rg) <= ranges::reserve_hint(rg)` is `true`, or

(3.2) — `R` models `ranges::forward_range` and `R` does not model `ranges::approximately_sized_range`.

For the declarations taking a pair of `InputIterator`, performs at most one reallocation if `InputIterator` meets the *Cpp17ForwardIterator* requirements.

```
constexpr iterator erase(const_iterator position);
constexpr iterator erase(const_iterator first, const_iterator last);
constexpr void pop_back();
```

4 *Effects*: Invalidates iterators and references at or after the point of the erase.

5 *Throws*: Nothing unless an exception is thrown by the assignment operator or move assignment operator of `T`.

6 *Complexity*: The destructor of `T` is called the number of times equal to the number of the elements erased, but the assignment operator of `T` is called the number of times equal to the number of elements in the vector after the erased elements.

23.3.13.6 Erasure [vector.erasure]

```
template<class T, class Allocator, class U = T>
  constexpr typename vector<T, Allocator>::size_type
    erase(vector<T, Allocator>& c, const U& value);
```

1 *Effects*: Equivalent to:

```
auto it = remove(c.begin(), c.end(), value);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;
```

```
template<class T, class Allocator, class Predicate>
  constexpr typename vector<T, Allocator>::size_type
    erase_if(vector<T, Allocator>& c, Predicate pred);
```

2 *Effects*: Equivalent to:

```
auto it = remove_if(c.begin(), c.end(), pred);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;
```

23.3.14 Specialization of `vector` for `bool` [vector.bool]

23.3.14.1 Partial class template specialization `vector<bool, Allocator>` [vector.bool.pspc]

1 To optimize space allocation, a partial specialization of `vector` for `bool` elements is provided:

```
namespace std {
  template<class Allocator>
  class vector<bool, Allocator> {
  public:
    // types
    using value_type             = bool;
    using allocator_type         = Allocator;
    using pointer                = implementation-defined;
    using const_pointer          = implementation-defined;
    using const_reference        = bool;
    using size_type              = implementation-defined; // see 23.2
    using difference_type        = implementation-defined; // see 23.2
    using iterator               = implementation-defined; // see 23.2
    using const_iterator         = implementation-defined; // see 23.2
    using reverse_iterator       = std::reverse_iterator<iterator>;
    using const_reverse_iterator = std::reverse_iterator<const_iterator>;

    // bit reference
    class reference {
    public:
      constexpr reference(const reference& x) noexcept;
      constexpr ~reference();
      constexpr reference& operator=(bool x) noexcept;
      constexpr reference& operator=(const reference& x) noexcept;
      constexpr const reference& operator=(bool x) const noexcept;
      constexpr operator bool() const noexcept;
      constexpr void flip() noexcept;   // flips the bit

      friend constexpr void swap(reference x, reference y) noexcept;
      friend constexpr void swap(reference x, bool& y) noexcept;
      friend constexpr void swap(bool& x, reference y) noexcept;
    };

    // construct/copy/destroy
    constexpr vector() noexcept(noexcept(Allocator())) : vector(Allocator()) { }
    constexpr explicit vector(const Allocator&) noexcept;
    constexpr explicit vector(size_type n, const Allocator& = Allocator());
    constexpr vector(size_type n, const bool& value, const Allocator& = Allocator());
    template<class InputIterator>
      constexpr vector(InputIterator first, InputIterator last, const Allocator& = Allocator());
    template<container-compatible-range<bool> R>
      constexpr vector(from_range_t, R&& rg, const Allocator& = Allocator());
    constexpr vector(const vector& x);
    constexpr vector(vector&& x) noexcept;
```

```
constexpr vector(const vector&, const type_identity_t<Allocator>&);
constexpr vector(vector&&, const type_identity_t<Allocator>&);
constexpr vector(initializer_list<bool>, const Allocator& = Allocator());
constexpr ~vector();
constexpr vector& operator=(const vector& x);
constexpr vector& operator=(vector&& x)
  noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
           allocator_traits<Allocator>::is_always_equal::value);
constexpr vector& operator=(initializer_list<bool>);
template<class InputIterator>
  constexpr void assign(InputIterator first, InputIterator last);
template<container-compatible-range<bool> R>
  constexpr void assign_range(R&& rg);
constexpr void assign(size_type n, const bool& t);
constexpr void assign(initializer_list<bool>);
constexpr allocator_type get_allocator() const noexcept;

// iterators
constexpr iterator               begin() noexcept;
constexpr const_iterator         begin() const noexcept;
constexpr iterator               end() noexcept;
constexpr const_iterator         end() const noexcept;
constexpr reverse_iterator       rbegin() noexcept;
constexpr const_reverse_iterator rbegin() const noexcept;
constexpr reverse_iterator       rend() noexcept;
constexpr const_reverse_iterator rend() const noexcept;

constexpr const_iterator         cbegin() const noexcept;
constexpr const_iterator         cend() const noexcept;
constexpr const_reverse_iterator crbegin() const noexcept;
constexpr const_reverse_iterator crend() const noexcept;

// capacity
constexpr bool empty() const noexcept;
constexpr size_type size() const noexcept;
constexpr size_type max_size() const noexcept;
constexpr size_type capacity() const noexcept;
constexpr void      resize(size_type sz, bool c = false);
constexpr void      reserve(size_type n);
constexpr void      shrink_to_fit();

// element access
constexpr reference       operator[](size_type n);
constexpr const_reference operator[](size_type n) const;
constexpr reference       at(size_type n);
constexpr const_reference at(size_type n) const;
constexpr reference       front();
constexpr const_reference front() const;
constexpr reference       back();
constexpr const_reference back() const;

// modifiers
template<class... Args> constexpr reference emplace_back(Args&&... args);
constexpr void push_back(const bool& x);
template<container-compatible-range<bool> R>
  constexpr void append_range(R&& rg);
constexpr void pop_back();
template<class... Args> constexpr iterator emplace(const_iterator position, Args&&... args);
constexpr iterator insert(const_iterator position, const bool& x);
constexpr iterator insert(const_iterator position, size_type n, const bool& x);
template<class InputIterator>
  constexpr iterator insert(const_iterator position,
                            InputIterator first, InputIterator last);
```

```
    template<container-compatible-range<bool> R>
      constexpr iterator insert_range(const_iterator position, R&& rg);
    constexpr iterator insert(const_iterator position, initializer_list<bool> il);

    constexpr iterator erase(const_iterator position);
    constexpr iterator erase(const_iterator first, const_iterator last);
    constexpr void swap(vector&)
      noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
               allocator_traits<Allocator>::is_always_equal::value);
    constexpr void flip() noexcept;     // flips all bits
    constexpr void clear() noexcept;
  };
}
```

2 Unless described below, all operations have the same requirements and semantics as the `vector` primary template, except that operations dealing with the `bool` value type map to bit values in the container storage and `allocator_traits::construct` (20.2.9.3) is not used to construct these values.

3 There is no requirement that the data be stored as a contiguous allocation of `bool` values. A space-optimized representation of bits is recommended instead.

4 `reference` is a class that simulates a reference to a single bit in the sequence.

```
constexpr reference::reference(const reference& x) noexcept;
```

5 *Effects*: Initializes `*this` to refer to the same bit as `x`.

```
constexpr reference::~reference();
```

6 *Effects*: None.

```
constexpr reference& reference::operator=(bool x) noexcept;
constexpr reference& reference::operator=(const reference& x) noexcept;
constexpr const reference& reference::operator=(bool x) const noexcept;
```

7 *Effects*: Sets the bit referred to by `*this` when `bool(x)` is `true`, and clears it otherwise.

8 *Returns*: `*this`.

```
constexpr reference::operator bool() const noexcept;
```

9 *Returns*: `true` if the value of the bit referred to by `*this` is one, `false` otherwise.

```
constexpr void reference::flip() noexcept;
```

10 *Effects*: Equivalent to `*this = !*this`.

```
constexpr void swap(reference x, reference y) noexcept;
constexpr void swap(reference x, bool& y) noexcept;
constexpr void swap(bool& x, reference y) noexcept;
```

11 *Effects*: Exchanges the values denoted by `x` and `y` as if by:

```
bool b = x;
x = y;
y = b;
```

```
constexpr void flip() noexcept;
```

12 *Effects*: Replaces each element in the container with its complement.

```
template<class Allocator> struct hash<vector<bool, Allocator>>;
```

13 The specialization is enabled (22.10.19).

```
template<class T>
  constexpr bool is-vector-bool-reference = see below;
```

14 The expression *is-vector-bool-reference*`<T>` is `true` if `T` denotes the type `vector<bool, Alloc>::reference` for some type `Alloc` and `vector<bool, Alloc>` is not a program-defined specialization.

23.3.14.2 Formatter specialization for `vector<bool>` [vector.bool.fmt]

```
namespace std {
  template<class T, class charT>
    requires is-vector-bool-reference<T>
  struct formatter<T, charT> {
  private:
    formatter<bool, charT> underlying_;        // exposition only

  public:
    template<class ParseContext>
      constexpr typename ParseContext::iterator
        parse(ParseContext& ctx);

    template<class FormatContext>
      constexpr typename FormatContext::iterator
        format(const T& ref, FormatContext& ctx) const;
  };
}

template<class ParseContext>
  constexpr typename ParseContext::iterator
    parse(ParseContext& ctx);
```

1 Equivalent to: `return underlying_.parse(ctx);`

```
template<class FormatContext>
  constexpr typename FormatContext::iterator
    format(const T& ref, FormatContext& ctx) const;
```

2 Equivalent to: `return underlying_.format(ref, ctx);`

23.3.15 Header `<inplace_vector>` synopsis [inplace.vector.syn]

```
// mostly freestanding
#include <compare>              // see 17.12.1
#include <initializer_list>     // see 17.11.2

namespace std {
  // 23.3.16, class template inplace_vector
  template<class T, size_t N> class inplace_vector;             // partially freestanding

  // 23.3.16.6, erasure
  template<class T, size_t N, class U = T>
    constexpr typename inplace_vector<T, N>::size_type
      erase(inplace_vector<T, N>& c, const U& value);
  template<class T, size_t N, class Predicate>
    constexpr typename inplace_vector<T, N>::size_type
      erase_if(inplace_vector<T, N>& c, Predicate pred);
}
```

23.3.16 Class template `inplace_vector` [inplace.vector]

23.3.16.1 Overview [inplace.vector.overview]

1 An `inplace_vector` is a contiguous container. Its capacity is fixed and its elements are stored within the `inplace_vector` object itself.

2 An `inplace_vector` meets all of the requirements of a container (23.2.2.2), of a reversible container (23.2.2.3), of a contiguous container, and of a sequence container, including most of the optional sequence container requirements (23.2.4). The exceptions are the `push_front`, `prepend_range`, `pop_front`, and `emplace_front` member functions, which are not provided. Descriptions are provided here only for operations on `inplace_vector` that are not described in one of these tables or for operations where there is additional semantic information.

3 For any `N`, `inplace_vector<T, N>::iterator` and `inplace_vector<T, N>::const_iterator` meet the constexpr iterator requirements.

4 Any member function of `inplace_vector<T, N>` that would cause the size to exceed `N` throws an exception of type `bad_alloc`.

5 Let `IV` denote a specialization of `inplace_vector<T, N>`. If `N` is zero, then `IV` is trivially copyable and empty, and `std::is_trivially_default_constructible_v<IV>` is `true`. Otherwise:

(5.1) — If `is_trivially_copy_constructible_v<T>` is `true`, then `IV` has a trivial copy constructor.

(5.2) — If `is_trivially_move_constructible_v<T>` is `true`, then `IV` has a trivial move constructor.

(5.3) — If `is_trivially_destructible_v<T>` is `true`, then:

(5.3.1) — `IV` has a trivial destructor.

(5.3.2) — If

```
is_trivially_copy_constructible_v<T> && is_trivially_copy_assignable_v<T>
```

is `true`, then `IV` has a trivial copy assignment operator.

(5.3.3) — If

```
is_trivially_move_constructible_v<T> && is_trivially_move_assignable_v<T>
```

is `true`, then `IV` has a trivial move assignment operator.

```
namespace std {
  template<class T, size_t N>
  class inplace_vector {
  public:
    // types:
    using value_type             = T;
    using pointer                = T*;
    using const_pointer          = const T*;
    using reference              = value_type&;
    using const_reference        = const value_type&;
    using size_type              = size_t;
    using difference_type        = ptrdiff_t;
    using iterator               = implementation-defined; // see 23.2
    using const_iterator         = implementation-defined; // see 23.2
    using reverse_iterator       = std::reverse_iterator<iterator>;
    using const_reverse_iterator = std::reverse_iterator<const_iterator>;

    // 23.3.16.2, construct/copy/destroy
    constexpr inplace_vector() noexcept;
    constexpr explicit inplace_vector(size_type n);                          // freestanding-deleted
    constexpr inplace_vector(size_type n, const T& value);                   // freestanding-deleted
    template<class InputIterator>
      constexpr inplace_vector(InputIterator first, InputIterator last);     // freestanding-deleted
    template<container-compatible-range<T> R>
      constexpr inplace_vector(from_range_t, R&& rg);                        // freestanding-deleted

constexpr iterator insert(const_iterator position, size_type n,       // freestanding-deleted
                          const T& x);
```

©ISO/IEC

```
    template<class InputIterator>
      constexpr iterator insert(const_iterator position,                    // freestanding-deleted
                                InputIterator first, InputIterator last);
    template<container-compatible-range<T> R>
      constexpr iterator insert_range(const_iterator position, R&& rg);     // freestanding-deleted
    constexpr iterator insert(const_iterator position,                      // freestanding-deleted
                              initializer_list<T> il);
    constexpr iterator erase(const_iterator position);
    constexpr iterator erase(const_iterator first, const_iterator last);
    constexpr void swap(inplace_vector& x)
      noexcept(N == 0 || (is_nothrow_swappable_v<T> &&
                          is_nothrow_move_constructible_v<T>));
    constexpr void clear() noexcept;

    friend constexpr bool operator==(const inplace_vector& x,
                                     const inplace_vector& y);
    friend constexpr auto
      operator<=>(const inplace_vector& x, const inplace_vector& y)
        requires requires (const T t) { synth-three-way(t, t); }
      {
        return lexicographical_compare_three_way(x.begin(), x.end(), y.begin(), y.end(),
                                                 synth-three-way);
      }
    friend constexpr void swap(inplace_vector& x, inplace_vector& y)
      noexcept(N == 0 || (is_nothrow_swappable_v<T> &&
                          is_nothrow_move_constructible_v<T>))
      { x.swap(y); }
  };
}
```

23.3.16.2 Constructors [inplace.vector.cons]

```
constexpr explicit inplace_vector(size_type n);
```

1 *Preconditions*: `T` is *Cpp17DefaultInsertable* into `inplace_vector`.

2 *Effects*: Constructs an `inplace_vector` with `n` default-inserted elements.

3 *Complexity*: Linear in `n`.

```
constexpr inplace_vector(size_type n, const T& value);
```

4 *Preconditions*: `T` is *Cpp17CopyInsertable* into `inplace_vector`.

5 *Effects*: Constructs an `inplace_vector` with `n` copies of `value`.

6 *Complexity*: Linear in `n`.

```
template<class InputIterator>
  constexpr inplace_vector(InputIterator first, InputIterator last);
```

7 *Effects*: Constructs an `inplace_vector` equal to the range [`first`, `last`).

8 *Complexity*: Linear in `distance(first, last)`.

```
template<container-compatible-range<T> R>
  constexpr inplace_vector(from_range_t, R&& rg);
```

9 *Mandates*: If `ranges::size(rg)` is a constant expression, then `ranges::size(rg)` $\leq$ `N`.

10 *Effects*: Constructs an `inplace_vector` with the elements of the range `rg`.

11 *Complexity*: Linear in `ranges::distance(rg)`.

23.3.16.3 Capacity [inplace.vector.capacity]

```
static constexpr size_type capacity() noexcept;
static constexpr size_type max_size() noexcept;
```

1 *Returns*: `N`.

```
constexpr void resize(size_type sz);
```

2 *Preconditions*: `T` is *Cpp17DefaultInsertable* into `inplace_vector`.

3 *Effects*: If `sz < size()`, erases the last `size() - sz` elements from the sequence. Otherwise, appends `sz - size()` default-inserted elements to the sequence.

4 *Remarks*: If an exception is thrown, there are no effects on `*this`.

```
constexpr void resize(size_type sz, const T& c);
```

5 *Preconditions*: `T` is *Cpp17CopyInsertable* into `inplace_vector`.

6 *Effects*: If `sz < size()`, erases the last `size() - sz` elements from the sequence. Otherwise, appends `sz - size()` copies of `c` to the sequence.

7 *Remarks*: If an exception is thrown, there are no effects on `*this`.

```
static constexpr void reserve(size_type n);
```

8 *Effects*: None.

9 *Throws*: `bad_alloc` if `n > capacity()` is `true`.

```
static constexpr void shrink_to_fit() noexcept;
```

10 *Effects*: None.

23.3.16.4 Data [inplace.vector.data]

```
constexpr       T* data()       noexcept;
constexpr const T* data() const noexcept;
```

1 *Returns*: A pointer such that [`data()`, `data() + size()`) is a valid range. For a non-empty `inplace_vector`, `data() == addressof(front())` is `true`.

2 *Complexity*: Constant time.

23.3.16.5 Modifiers [inplace.vector.modifiers]

```
constexpr iterator insert(const_iterator position, const T& x);
constexpr iterator insert(const_iterator position, T&& x);
constexpr iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
  constexpr iterator insert(const_iterator position, InputIterator first, InputIterator last);
template<container-compatible-range<T> R>
  constexpr iterator insert_range(const_iterator position, R&& rg);
constexpr iterator insert(const_iterator position, initializer_list<T> il);

template<class... Args>
  constexpr iterator emplace(const_iterator position, Args&&... args);
template<container-compatible-range<T> R>
  constexpr void append_range(R&& rg);
```

1 Let n be the value of `size()` before this call for the `append_range` overload, and `distance(begin, position)` otherwise.

2 *Complexity*: Linear in the number of elements inserted plus the distance to the end of the vector.

3 *Remarks*: If an exception is thrown other than by the copy constructor, move constructor, assignment operator, or move assignment operator of `T` or by any `InputIterator` operation, there are no effects. Otherwise, if an exception is thrown, then `size()` $\geq n$ and elements in the range `begin() +` $[0, n)$ are not modified.

```
constexpr reference push_back(const T& x);
constexpr reference push_back(T&& x);
template<class... Args>
  constexpr reference emplace_back(Args&&... args);
```

4 *Returns*: `back()`.

5 *Throws*: `bad_alloc` or any exception thrown by the initialization of the inserted element.

6 *Complexity*: Constant.

7 *Remarks*: If an exception is thrown, there are no effects on `*this`.

```
template<class... Args>
  constexpr optional<reference> try_emplace_back(Args&&... args);
constexpr optional<reference> try_push_back(const T& x);
constexpr optional<reference> try_push_back(T&& x);
```

8 Let `vals` denote a pack:

(8.1) — `std::forward<Args>(args)...` for the first overload,

(8.2) — `x` for the second overload,

(8.3) — `std::move(x)` for the third overload.

9 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `inplace_vector` from `vals...`.

10 *Effects*: If `size() < capacity()` is `true`, appends an object of type `T` direct-non-list-initialized with `vals...`. Otherwise, there are no effects.

11 *Returns*: `nullopt` if `size() == capacity()` is `true`, otherwise `optional<reference>(in_place, back())`.

12 *Throws*: Nothing unless an exception is thrown by the initialization of the inserted element.

13 *Complexity*: Constant.

14 *Remarks*: If an exception is thrown, there are no effects on `*this`.

```
template<class... Args>
  constexpr reference unchecked_emplace_back(Args&&... args);
```

15 *Preconditions*: `size() < capacity()` is `true`.

16 *Effects*: Equivalent to: `return *try_emplace_back(std::forward<Args>(args)...);`

```
constexpr reference unchecked_push_back(const T& x);
constexpr reference unchecked_push_back(T&& x);
```

17 *Preconditions*: `size() < capacity()` is `true`.

18 *Effects*: Equivalent to: `return *try_push_back(std::forward<decltype(x)>(x));`

```
constexpr iterator erase(const_iterator position);
constexpr iterator erase(const_iterator first, const_iterator last);
constexpr void pop_back();
```

19 *Effects*: Invalidates iterators and references at or after the point of the erase.

20 *Throws*: Nothing unless an exception is thrown by the assignment operator or move assignment operator of `T`.

21 *Complexity*: The destructor of `T` is called the number of times equal to the number of the elements erased, but the assignment operator of `T` is called the number of times equal to the number of elements after the erased elements.

```
constexpr void swap(inplace_vector& x) noexcept(
  N == 0 || (is_nothrow_swappable_v<T> && is_nothrow_move_constructible_v<T>));
```

22 *Preconditions*: `T` meets the *Cpp17MoveConstructible* requirements. Let M be `min(size(), x.size())`. For each non-negative integer $n < M$, `(*this)[`n`]` is swappable with `x[`n`]` (16.4.4.3).

23 *Effects*: Exchanges the contents of `*this` and `x`.

23.3.16.6 Erasure [inplace.vector.erasure]

```
template<class T, size_t N, class U = T>
  constexpr size_t erase(inplace_vector<T, N>& c, const U& value);
```

1 *Effects*: Equivalent to:

```
auto it = remove(c.begin(), c.end(), value);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;
```

```
template<class T, size_t N, class Predicate>
  constexpr size_t erase_if(inplace_vector<T, N>& c, Predicate pred);
```

2 *Effects*: Equivalent to:

```
auto it = remove_if(c.begin(), c.end(), pred);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;
```

23.4 Associative containers [associative]

23.4.1 General [associative.general]

1 The header <map> (23.4.2) defines the class templates map and multimap; the header <set> (23.4.5) defines the class templates set and multiset.

2 The following exposition-only alias templates may appear in deduction guides for associative containers:

```
template<class InputIterator>
  using iter-value-type = iterator_traits<InputIterator>::value_type;    // exposition only
template<class InputIterator>
  using iter-key-type = remove_cvref_t<
    tuple_element_t<0, iter-value-type<InputIterator>>>;                 // exposition only
template<class InputIterator>
  using iter-mapped-type = remove_cvref_t<
    tuple_element_t<1, iter-value-type<InputIterator>>>;                 // exposition only
template<class InputIterator>
  using iter-to-alloc-type = pair<
    const iter-key-type<InputIterator>,
    iter-mapped-type<InputIterator>>;                                    // exposition only
template<ranges::input_range Range>
  using range-key-type =
    remove_cvref_t<tuple_element_t<0, ranges::range_value_t<Range>>>;    // exposition only
template<ranges::input_range Range>
  using range-mapped-type =
    remove_cvref_t<tuple_element_t<1, ranges::range_value_t<Range>>>;    // exposition only
template<ranges::input_range Range>
  using range-to-alloc-type =
    pair<const range-key-type<Range>,
         range-mapped-type<Range>>;                                      // exposition only
```

23.4.2 Header <map> synopsis [associative.map.syn]

```
#include <compare>             // see 17.12.1
#include <initializer_list>    // see 17.11.2

namespace std {
  // 23.4.3, class template map
  template<class Key, class T, class Compare = less<Key>,
           class Allocator = allocator<pair<const Key, T>>>
    class map;

  template<class Key, class T, class Compare, class Allocator>
    constexpr bool operator==(const map<Key, T, Compare, Allocator>& x,
                              const map<Key, T, Compare, Allocator>& y);
  template<class Key, class T, class Compare, class Allocator>
    constexpr synth-three-way-result<pair<const Key, T>>
      operator<=>(const map<Key, T, Compare, Allocator>& x,
                  const map<Key, T, Compare, Allocator>& y);

  template<class Key, class T, class Compare, class Allocator>
    constexpr void swap(map<Key, T, Compare, Allocator>& x,
                        map<Key, T, Compare, Allocator>& y)
      noexcept(noexcept(x.swap(y)));
```

©ISO/IEC

```
  // 23.4.3.5, erasure for map
  template<class Key, class T, class Compare, class Allocator, class Predicate>
    constexpr typename map<Key, T, Compare, Allocator>::size_type
      erase_if(map<Key, T, Compare, Allocator>& c, Predicate pred);

  // 23.4.4, class template multimap
  template<class Key, class T, class Compare = less<Key>,
           class Allocator = allocator<pair<const Key, T>>>
    class multimap;

  template<class Key, class T, class Compare, class Allocator>
    constexpr bool operator==(const multimap<Key, T, Compare, Allocator>& x,
                              const multimap<Key, T, Compare, Allocator>& y);
  template<class Key, class T, class Compare, class Allocator>
    constexpr synth-three-way-result<pair<const Key, T>>
      operator<=>(const multimap<Key, T, Compare, Allocator>& x,
                  const multimap<Key, T, Compare, Allocator>& y);

  template<class Key, class T, class Compare, class Allocator>
    constexpr void swap(multimap<Key, T, Compare, Allocator>& x,
                        multimap<Key, T, Compare, Allocator>& y)
      noexcept(noexcept(x.swap(y)));

  // 23.4.4.4, erasure for multimap
  template<class Key, class T, class Compare, class Allocator, class Predicate>
    constexpr typename multimap<Key, T, Compare, Allocator>::size_type
      erase_if(multimap<Key, T, Compare, Allocator>& c, Predicate pred);

  namespace pmr {
    template<class Key, class T, class Compare = less<Key>>
      using map = std::map<Key, T, Compare,
                           polymorphic_allocator<pair<const Key, T>>>;

    template<class Key, class T, class Compare = less<Key>>
      using multimap = std::multimap<Key, T, Compare,
                                     polymorphic_allocator<pair<const Key, T>>>;
  }
}
```

23.4.3 Class template map [map]

23.4.3.1 Overview [map.overview]

1 A map is an associative container that supports unique keys (i.e., contains at most one of each key value) and provides for fast retrieval of values of another type T based on the keys. The map class supports bidirectional iterators.

2 A map meets all of the requirements of a container (23.2.2.2), of a reversible container (23.2.2.3), of an allocator-aware container (23.2.2.5), and of an associative container (23.2.7). A map also provides most operations described in 23.2.7 for unique keys. This means that a map supports the a_uniq operations in 23.2.7 but not the a_eq operations. For a map<Key,T> the key_type is Key and the value_type is pair<const Key,T>. Descriptions are provided here only for operations on map that are not described in one of those tables or for operations where there is additional semantic information.

3 The types iterator and const_iterator meet the constexpr iterator requirements (24.3.1).

```
namespace std {
  template<class Key, class T, class Compare = less<Key>,
           class Allocator = allocator<pair<const Key, T>>>
  class map {
  public:
    // types
    using key_type               = Key;
    using mapped_type            = T;
    using value_type             = pair<const Key, T>;
    using key_compare            = Compare;
```

```
using allocator_type         = Allocator;
using pointer                = allocator_traits<Allocator>::pointer;
using const_pointer          = allocator_traits<Allocator>::const_pointer;
using reference              = value_type&;
using const_reference        = const value_type&;
using size_type              = implementation-defined; // see 23.2
using difference_type        = implementation-defined; // see 23.2
using iterator               = implementation-defined; // see 23.2
using const_iterator         = implementation-defined; // see 23.2
using reverse_iterator       = std::reverse_iterator<iterator>;
using const_reverse_iterator = std::reverse_iterator<const_iterator>;
using node_type              = unspecified;
using insert_return_type     = insert-return-type<iterator, node_type>;

class value_compare {
protected:
  Compare comp;
  constexpr value_compare(Compare c) : comp(c) {}

public:

             less<iter-key-type<InputIterator>>, Allocator>;

  template<ranges::input_range R, class Allocator>
    map(from_range_t, R&&, Allocator)
      -> map<range-key-type<R>, range-mapped-type<R>, less<range-key-type<R>>, Allocator>;

  template<class Key, class T, class Allocator>
    map(initializer_list<pair<Key, T>>, Allocator) -> map<Key, T, less<Key>, Allocator>;
}
```

23.4.3.2 Constructors, copy, and assignment [map.cons]

```
constexpr explicit map(const Compare& comp, const Allocator& = Allocator());
```

1 *Effects*: Constructs an empty `map` using the specified comparison object and allocator.

2 *Complexity*: Constant.

```
template<class InputIterator>
  constexpr map(InputIterator first, InputIterator last,
                const Compare& comp = Compare(), const Allocator& = Allocator());
```

3 *Effects*: Constructs an empty `map` using the specified comparison object and allocator, and inserts elements from the range [`first`, `last`).

4 *Complexity*: Linear in N if the range [`first`, `last`) is already sorted with respect to `comp` and otherwise $N \log N$, where N is `last - first`.

```
template<container-compatible-range<value_type> R>
  constexpr map(from_range_t, R&& rg, const Compare& comp = Compare(),
                const Allocator& = Allocator());
```

5 *Effects*: Constructs an empty `map` using the specified comparison object and allocator, and inserts elements from the range `rg`.

6 *Complexity*: Linear in N if `rg` is already sorted with respect to `comp` and otherwise $N \log N$, where N is `ranges::distance(rg)`.

23.4.3.3 Element access [map.access]

```
constexpr mapped_type& operator[](const key_type& x);
```

1 *Effects*: Equivalent to: `return try_emplace(x).first->second;`

```
constexpr mapped_type& operator[](key_type&& x);
```

2 *Effects*: Equivalent to: `return try_emplace(std::move(x)).first->second;`

```
template<class K> constexpr mapped_type& operator[](K&& x);
```

3 *Constraints*: The *qualified-id* `Compare::is_transparent` is valid and denotes a type.

4 *Effects*: Equivalent to: `return try_emplace(std::forward<K>(x)).first->second;`

```
constexpr mapped_type&       at(const key_type& x);
constexpr const mapped_type& at(const key_type& x) const;
```

5 *Returns*: A reference to the `mapped_type` corresponding to `x` in `*this`.

6 *Throws*: An exception object of type `out_of_range` if no such element is present.

7 *Complexity*: Logarithmic.

```
template<class K> constexpr mapped_type&       at(const K& x);
template<class K> constexpr const mapped_type& at(const K& x) const;
```

8 *Constraints*: The *qualified-id* `Compare::is_transparent` is valid and denotes a type.

9 *Preconditions*: The expression `find(x)` is well-formed and has well-defined behavior.

10 *Returns*: A reference to `find(x)->second`.

11 *Throws*: An exception object of type `out_of_range` if `find(x) == end()` is `true`.

12 *Complexity*: Logarithmic.

23.4.3.4 Modifiers [map.modifiers]

```
template<class P>
  constexpr pair<iterator, bool> insert(P&& x);
template<class P>
  constexpr iterator insert(const_iterator position, P&& x);
```

1 *Constraints*: `is_constructible_v<value_type, P&&>` is `true`.

2 *Effects*: The first form is equivalent to `return emplace(std::forward<P>(x))`. The second form is equivalent to `return emplace_hint(position, std::forward<P>(x))`.

```
template<class... Args>
  constexpr pair<iterator, bool> try_emplace(const key_type& k, Args&&... args);
template<class... Args>
  constexpr iterator try_emplace(const_iterator hint, const key_type& k, Args&&... args);
```

3 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `map` from `piecewise_construct`, `forward_as_tuple(k)`, `forward_as_tuple(std::forward<Args>(args)...)`.

4 *Effects*: If the map already contains an element whose key is equivalent to `k`, there is no effect. Otherwise inserts an object of type `value_type` constructed with `piecewise_construct`, `forward_as_tuple(k)`, `forward_as_tuple(std::forward<Args>(args)...)`.

5 *Returns*: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

6 *Complexity*: The same as `emplace` and `emplace_hint`, respectively.

```
template<class... Args>
  constexpr pair<iterator, bool> try_emplace(key_type&& k, Args&&... args);
template<class... Args>
  constexpr iterator try_emplace(const_iterator hint, key_type&& k, Args&&... args);
```

7 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `map` from `piecewise_construct`, `forward_as_tuple(std::move(k))`, `forward_as_tuple(std::forward<Args>(args)...)`.

8 *Effects*: If the map already contains an element whose key is equivalent to `k`, there is no effect. Otherwise inserts an object of type `value_type` constructed with `piecewise_construct`, `forward_as_tuple(std::move(k))`, `forward_as_tuple(std::forward<Args>(args)...)`.

9 *Returns*: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

10 *Complexity*: The same as `emplace` and `emplace_hint`, respectively.

```
template<class K, class... Args>
  constexpr pair<iterator, bool> try_emplace(K&& k, Args&&... args);
```

```
template<class K, class... Args>
  constexpr iterator try_emplace(const_iterator hint, K&& k, Args&&... args);
```

11 *Constraints*: The *qualified-id* `Compare::is_transparent` is valid and denotes a type. For the first overload, `is_convertible_v<K&&, const_iterator>` and `is_convertible_v<K&&, iterator>` are both `false`.

12 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `map` from `piecewise_construct, forward_as_tuple(std::forward<K>(k)), forward_as_tuple(std::forward<Args>(args)...)`.

13 *Effects*: If the map already contains an element whose key is equivalent to `k`, there is no effect. Otherwise, let `r` be `equal_range(k)`. Constructs an object `u` of type `value_type` with `piecewise_construct, forward_as_tuple(std::forward<K>(k)), forward_as_tuple(std::forward<Args>(args)...)`. If `equal_range(u.first) == r` is `false`, the behavior is undefined. Inserts `u` into `*this`.

14 *Returns*: For the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

15 *Complexity*: The same as `emplace` and `emplace_hint`, respectively.

```
template<class M>
  constexpr pair<iterator, bool> insert_or_assign(const key_type& k, M&& obj);
template<class M>
  constexpr iterator insert_or_assign(const_iterator hint, const key_type& k, M&& obj);
```

16 *Mandates*: `is_assignable_v<mapped_type&, M&&>` is `true`.

17 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `map` from `k`, `std::forward<M>(obj)`.

18 *Effects*: If the map already contains an element `e` whose key is equivalent to `k`, assigns `std::forward<M>(obj)` to `e.second`. Otherwise inserts an object of type `value_type` constructed with `k`, `std::forward<M>(obj)`.

19 *Returns*: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

20 *Complexity*: The same as `emplace` and `emplace_hint`, respectively.

```
template<class M>
  constexpr pair<iterator, bool> insert_or_assign(key_type&& k, M&& obj);
template<class M>
  constexpr iterator insert_or_assign(const_iterator hint, key_type&& k, M&& obj);
```

21 *Mandates*: `is_assignable_v<mapped_type&, M&&>` is `true`.

22 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `map` from `std::move(k)`, `std::forward<M>(obj)`.

23 *Effects*: If the map already contains an element `e` whose key is equivalent to `k`, assigns `std::forward<M>(obj)` to `e.second`. Otherwise inserts an object of type `value_type` constructed with `std::move(k)`, `std::forward<M>(obj)`.

24 *Returns*: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

25 *Complexity*: The same as `emplace` and `emplace_hint`, respectively.

```
template<class K, class M>
  constexpr pair<iterator, bool> insert_or_assign(K&& k, M&& obj);
template<class K, class M>
  constexpr iterator insert_or_assign(const_iterator hint, K&& k, M&& obj);
```

26 *Constraints*: The *qualified-id* `Compare::is_transparent` is valid and denotes a type.

27 *Mandates*: `is_assignable_v<mapped_type&, M&&>` is `true`.

28 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `map` from `std::forward<K>(k), std::forward<M>(obj)`.

29 *Effects*: If the map already contains an element `e` whose key is equivalent to `k`, assigns `std::forward<M>(obj)` to `e.second`. Otherwise, let `r` be `equal_range(k)`. Constructs an object `u` of type `value_type` with `std::forward<K>(k), std::forward<M>(obj)`. If `equal_range(u.first) == r` is `false`, the behavior is undefined. Inserts `u` into `*this`.

©ISO/IEC

30 *Returns*: For the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

31 *Complexity*: The same as `emplace` and `emplace_hint`, respectively.

23.4.3.5 Erasure [map.erasure]

```
template<class Key, class T, class Compare, class Allocator, class Predicate>
  typename map<Key, T, Compare, Allocator>::size_type
    constexpr erase_if(map<Key, T, Compare, Allocator>& c, Predicate pred);
```

1 *Effects*: Equivalent to:

```
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
}
return original_size - c.size();
```

23.4.4 Class template `multimap` [multimap]

23.4.4.1 Overview [multimap.overview]

1 A `multimap` is an associative container that supports equivalent keys (i.e., possibly containing multiple copies of the same key value) and provides for fast retrieval of values of another type `T` based on the keys. The `multimap` class supports bidirectional iterators.

2 A `multimap` meets all of the requirements of a container (23.2.2.2), of a reversible container (23.2.2.3), of an allocator-aware container (23.2.2.5), and of an associative container (23.2.7). A `multimap` also provides most operations described in 23.2.7 for equal keys. This means that a `multimap` supports the `a_eq` operations in 23.2.7 but not the `a_uniq` operations. For a `multimap<Key,T>` the `key_type` is `Key` and the `value_type` is `pair<const Key,T>`. Descriptions are provided here only for operations on `multimap` that are not described in one of those tables or for operations where there is additional semantic information.

3 The types `iterator` and `const_iterator` meet the constexpr iterator requirements (24.3.1).

```
namespace std {
  template<class Key, class T, class Compare = less<Key>,
           class Allocator = allocator<pair<const Key, T>>>
  class multimap {
  public:
    // types
    using key_type               = Key;
    using mapped_type            = T;
    using value_type             = pair<const Key, T>;
    using key_compare            = Compare;
    using allocator_type         = Allocator;
    using pointer                = allocator_traits<Allocator>::pointer;
    using const_pointer          = allocator_traits<Allocator>::const_pointer;
    using reference              = value_type&;
    using const_reference        = const value_type&;
    using size_type              = implementation-defined; // see 23.2

}
```

23.4.4.2 Constructors [multimap.cons]

```
constexpr explicit multimap(const Compare& comp, const Allocator& = Allocator());
```

1 *Effects*: Constructs an empty `multimap` using the specified comparison object and allocator.

2 *Complexity*: Constant.

```
template<class InputIterator>
  constexpr multimap(InputIterator first, InputIterator last,
                     const Compare& comp = Compare(), const Allocator& = Allocator());
```

3 *Effects*: Constructs an empty `multimap` using the specified comparison object and allocator, and inserts elements from the range [`first`, `last`).

4 *Complexity*: Linear in N if the range [`first`, `last`) is already sorted with respect to `comp` and otherwise $N \log N$, where N is `last - first`.

```
template<container-compatible-range<value_type> R>
  constexpr multimap(from_range_t, R&& rg,
                     const Compare& comp = Compare(), const Allocator& = Allocator());
```

5 *Effects*: Constructs an empty `multimap` using the specified comparison object and allocator, and inserts elements from the range `rg`.

6 *Complexity*: Linear in N if `rg` is already sorted with respect to `comp` and otherwise $N \log N$, where N is `ranges::distance(rg)`.

23.4.4.3 Modifiers [multimap.modifiers]

```
template<class P> constexpr iterator insert(P&& x);
```

```
template<class P> constexpr iterator insert(const_iterator position, P&& x);
```

1 *Constraints*: `is_constructible_v<value_type, P&&>` is `true`.

2 *Effects*: The first form is equivalent to `return emplace(std::forward<P>(x))`. The second form is equivalent to `return emplace_hint(position, std::forward<P>(x))`.

23.4.4.4 Erasure [multimap.erasure]

```
template<class Key, class T, class Compare, class Allocator, class Predicate>
  typename multimap<Key, T, Compare, Allocator>::size_type
    constexpr erase_if(multimap<Key, T, Compare, Allocator>& c, Predicate pred);
```

1 *Effects*: Equivalent to:

```
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
}
return original_size - c.size();
```

23.4.5 Header <set> synopsis [associative.set.syn]

```
#include <compare>             // see 17.12.1
#include <initializer_list>    // see 17.11.2

namespace std {
  // 23.4.6, class template set
  template<class Key, class Compare = less<Key>, class Allocator = allocator<Key>>
    class set;

  }
}
```

23.4.6 Class template set [set]

23.4.6.1 Overview [set.overview]

1 A `set` is an associative container that supports unique keys (i.e., contains at most one of each key value) and provides for fast retrieval of the keys themselves. The `set` class supports bidirectional iterators.

2 A `set` meets all of the requirements of a container (23.2.2.2), of a reversible container (23.2.2.3), of an allocator-aware container (23.2.2.5), and of an associative container (23.2.7). A `set` also provides most operations described in 23.2.7 for unique keys. This means that a `set` supports the `a_uniq` operations in 23.2.7 but not the `a_eq` operations. For a `set<Key>` both the `key_type` and `value_type` are `Key`. Descriptions are provided here only for operations on `set` that are not described in one of these tables and for operations where there is additional semantic information.

3 The types `iterator` and `const_iterator` meet the constexpr iterator requirements (24.3.1).

```
namespace std {
  template<class Key, class Compare = less<Key>,
           class Allocator = allocator<Key>>
  class set {
  public:
    // types
    using key_type               = Key;
    using key_compare            = Compare;
    using value_type             = Key;
    using value_compare          = Compare;
    using allocator_type         = Allocator;
    using pointer                = allocator_traits<Allocator>::pointer;
    using const_pointer          = allocator_traits<Allocator>::const_pointer;
    using reference              = value_type&;
    using const_reference        = const value_type&;
    using size_type              = implementation-defined; // see 23.2

             less<iter-value-type<InputIterator>>, Allocator>;

  template<ranges::input_range R, class Allocator>
    set(from_range_t, R&&, Allocator)
      -> set<ranges::range_value_t<R>, less<ranges::range_value_t<R>>, Allocator>;

  template<class Key, class Allocator>
    set(initializer_list<Key>, Allocator) -> set<Key, less<Key>, Allocator>;
}
```

23.4.6.2 Constructors, copy, and assignment [set.cons]

```
constexpr explicit set(const Compare& comp, const Allocator& = Allocator());
```

1 *Effects*: Constructs an empty `set` using the specified comparison object and allocator.

2 *Complexity*: Constant.

```
template<class InputIterator>
  constexpr set(InputIterator first, InputIterator last,
                const Compare& comp = Compare(), const Allocator& = Allocator());
```

3 *Effects*: Constructs an empty `set` using the specified comparison object and allocator, and inserts elements from the range [`first`, `last`).

4 *Complexity*: Linear in N if the range [`first`, `last`) is already sorted with respect to `comp` and otherwise $N \log N$, where N is `last - first`.

```
template<container-compatible-range<value_type> R>
  constexpr set(from_range_t, R&& rg, const Compare& comp = Compare(),
                const Allocator& = Allocator());
```

5 *Effects*: Constructs an empty `set` using the specified comparison object and allocator, and inserts elements from the range `rg`.

6 *Complexity*: Linear in N if `rg` is already sorted with respect to `comp` and otherwise $N \log N$, where N is `ranges::distance(rg)`.

23.4.6.3 Erasure [set.erasure]

```
template<class Key, class Compare, class Allocator, class Predicate>
  constexpr typename set<Key, Compare, Allocator>::size_type
    erase_if(set<Key, Compare, Allocator>& c, Predicate pred);
```

1 *Effects*: Equivalent to:

```
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
}
```

```
  return original_size - c.size();
```

23.4.6.4 Modifiers [set.modifiers]

```
template<class K> constexpr pair<iterator, bool> insert(K&& x);
template<class K> constexpr iterator insert(const_iterator hint, K&& x);
```

1 *Constraints*: The *qualified-id* `Compare::is_transparent` is valid and denotes a type. For the second overload, `is_convertible_v<K&&, const_iterator>` and `is_convertible_v<K&&, iterator>` are both `false`.

2 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `set` from `std::forward<K>(x)`.

3 *Effects*: If the set already contains an element that is equivalent to `x`, there is no effect. Otherwise, let `r` be `equal_range(x)`. Constructs an object `u` of type `value_type` with `std::forward<K>(x)`. If `equal_range(u) == r` is `false`, the behavior is undefined. Inserts `u` into `*this`.

4 *Returns*: For the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the set element that is equivalent to `x`.

5 *Complexity*: Logarithmic.

23.4.7 Class template `multiset` [multiset]

23.4.7.1 Overview [multiset.overview]

1 A `multiset` is an associative container that supports equivalent keys (i.e., possibly contains multiple copies of the same key value) and provides for fast retrieval of the keys themselves. The `multiset` class supports bidirectional iterators.

2 A `multiset` meets all of the requirements of a container (23.2.2.2), of a reversible container (23.2.2.3), of an allocator-aware container (23.2.2.5), and of an associative container (23.2.7). `multiset` also provides most operations described in 23.2.7 for duplicate keys. This means that a `multiset` supports the `a_eq` operations in 23.2.7 but not the `a_uniq` operations. For a `multiset<Key>` both the `key_type` and `value_type` are `Key`. Descriptions are provided here only for operations on `multiset` that are not described in one of these tables and for operations where there is additional semantic information.

3 The types `iterator` and `const_iterator` meet the constexpr iterator requirements (24.3.1).

```
namespace std {
  template<class Key, class Compare = less<Key>,
           class Allocator = allocator<Key>>
  class multiset {
  public:
    // types
    using key_type               = Key;
    using key_compare            = Compare;
    using value_type             = Key;
    using value_compare          = Compare;
    using allocator_type         = Allocator;
    using pointer                = allocator_traits<Allocator>::pointer;
    using const_pointer          = allocator_traits<Allocator>::const_pointer;

                     const Compare& comp = Compare(), const Allocator& = Allocator());
```

3 *Effects*: Constructs an empty `multiset` using the specified comparison object and allocator, and inserts elements from the range [`first`, `last`).

4 *Complexity*: Linear in N if the range [`first`, `last`) is already sorted with respect to `comp` and otherwise $N \log N$, where N is `last - first`.

```
template<container-compatible-range<value_type> R>
  constexpr multiset(from_range_t, R&& rg, const Compare& comp = Compare(),
                     const Allocator& = Allocator());
```

5 *Effects*: Constructs an empty `multiset` using the specified comparison object and allocator, and inserts elements from the range `rg`.

6 *Complexity*: Linear in N if `rg` is already sorted with respect to `comp` and otherwise $N \log N$, where N is `ranges::distance(rg)`.

23.4.7.3 Erasure [multiset.erasure]

```
template<class Key, class Compare, class Allocator, class Predicate>
  constexpr typename multiset<Key, Compare, Allocator>::size_type
    erase_if(multiset<Key, Compare, Allocator>& c, Predicate pred);
```

1 *Effects*: Equivalent to:

```
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
}
return original_size - c.size();
```

23.5 Unordered associative containers [unord]

23.5.1 General [unord.general]

1 The header <unordered_map> (23.5.2) defines the class templates unordered_map and unordered_multimap; the header <unordered_set> (23.5.5) defines the class templates unordered_set and unordered_multiset.

2 The exposition-only alias templates *iter-value-type*, *iter-key-type*, *iter-mapped-type*, *iter-to-alloc-type*, *range-key-type*, *range-mapped-type*, and *range-to-alloc-type* defined in 23.4.1 may appear in deduction guides for unordered containers.

23.5.2 Header <unordered_map> synopsis [unord.map.syn]

```
#include <compare>             // see 17.12.1
#include <initializer_list>    // see 17.11.2

namespace std {
  // 23.5.3, class template unordered_map
  template<class Key,
           class T,
           class Hash = hash<Key>,
           class Pred = equal_to<Key>,
           class Alloc = allocator<pair<const Key, T>>>
    class unordered_map;

  // 23.5.4, class template unordered_multimap
  template<class Key,
           class T,
           class Hash = hash<Key>,
           class Pred = equal_to<Key>,
           class Alloc = allocator<pair<const Key, T>>>
    class unordered_multimap;

  template<class Key, class T, class Hash, class Pred, class Alloc>
    constexpr bool operator==(const unordered_map<Key, T, Hash, Pred, Alloc>& a,
                              const unordered_map<Key, T, Hash, Pred, Alloc>& b);

  template<class Key, class T, class Hash, class Pred, class Alloc>
    constexpr bool operator==(const unordered_multimap<Key, T, Hash, Pred, Alloc>& a,
                              const unordered_multimap<Key, T, Hash, Pred, Alloc>& b);

  template<class Key, class T, class Hash, class Pred, class Alloc>
    constexpr void swap(unordered_map<Key, T, Hash, Pred, Alloc>& x,
                        unordered_map<Key, T, Hash, Pred, Alloc>& y)
      noexcept(noexcept(x.swap(y)));

  template<class Key, class T, class Hash, class Pred, class Alloc>
    constexpr void swap(unordered_multimap<Key, T, Hash, Pred, Alloc>& x,
                        unordered_multimap<Key, T, Hash, Pred, Alloc>& y)
      noexcept(noexcept(x.swap(y)));

  // 23.5.3.5, erasure for unordered_map
  template<class K, class T, class H, class P, class A, class Predicate>
    constexpr typename unordered_map<K, T, H, P, A>::size_type
      erase_if(unordered_map<K, T, H, P, A>& c, Predicate pred);

  // 23.5.4.4, erasure for unordered_multimap
  template<class K, class T, class H, class P, class A, class Predicate>
    constexpr typename unordered_multimap<K, T, H, P, A>::size_type
      erase_if(unordered_multimap<K, T, H, P, A>& c, Predicate pred);

  namespace pmr {
    template<class Key,
             class T,
             class Hash = hash<Key>,

```

```
    using unordered_map =
      std::unordered_map<Key, T, Hash, Pred,
                         polymorphic_allocator<pair<const Key, T>>>;
  template<class Key,
           class T,
           class Hash = hash<Key>,
           class Pred = equal_to<Key>>
    using unordered_multimap =
      std::unordered_multimap<Key, T, Hash, Pred,
                              polymorphic_allocator<pair<const Key, T>>>;

}
}
```

23.5.3 Class template `unordered_map` [unord.map]

23.5.3.1 Overview [unord.map.overview]

1 An `unordered_map` is an unordered associative container that supports unique keys (an `unordered_map` contains at most one of each key value) and that associates values of another type `mapped_type` with the keys. The `unordered_map` class supports forward iterators.

2 An `unordered_map` meets all of the requirements of a container (23.2.2.2), of an allocator-aware container (23.2.2.5), and of an unordered associative container (23.2.8). It provides the operations described in the preceding requirements table for unique keys; that is, an `unordered_map` supports the `a_uniq` operations in that table, not the `a_eq` operations. For an `unordered_map<Key, T>` the `key_type` is `Key`, the `mapped_type` is `T`, and the `value_type` is `pair<const Key, T>`.

3 Subclause 23.5.3 only describes operations on `unordered_map` that are not described in one of the requirement tables, or for which there is additional semantic information.

4 The types `iterator`, `const_iterator`, `local_iterator`, and `const_local_iterator` meet the constexpr iterator requirements (24.3.1).

```
namespace std {
  template<class Key,
           class T,
           class Hash = hash<Key>,
           class Pred = equal_to<Key>,
           class Allocator = allocator<pair<const Key, T>>>
  class unordered_map {
  public:
    // types
    using key_type             = Key;
    using mapped_type          = T;
    using value_type           = pair<const Key, T>;
    using hasher               = Hash;
    using key_equal            = Pred;
    using allocator_type       = Allocator;
    using pointer              = allocator_traits<Allocator>::pointer;
    using const_pointer        = allocator_traits<Allocator>::const_pointer;
    using reference            = value_type&;
    using const_reference      = const value_type&;
    using size_type            = implementation-defined; // see 23.2
    using difference_type      = implementation-defined; // see 23.2

    -> unordered_map<Key, T, hash<Key>, equal_to<Key>, Allocator>;
```

```
  template<class Key, class T, class Hash, class Allocator>
    unordered_map(initializer_list<pair<Key, T>>, typename see below::size_type, Hash,
                  Allocator)
      -> unordered_map<Key, T, Hash, equal_to<Key>, Allocator>;
}
```

5 A `size_type` parameter type in an `unordered_map` deduction guide refers to the `size_type` member type of the type deduced by the deduction guide.

23.5.3.2 Constructors [unord.map.cnstr]

```
constexpr unordered_map() : unordered_map(size_type(see below)) { }
constexpr explicit unordered_map(size_type n, const hasher& hf = hasher(),
                                 const key_equal& eql = key_equal(),
                                 const allocator_type& a = allocator_type());
```

1 *Effects*: Constructs an empty `unordered_map` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. For the default constructor, the number of buckets is implementation-defined. `max_load_factor()` returns `1.0`.

2 *Complexity*: Constant.

```
template<class InputIterator>
  constexpr unordered_map(InputIterator f, InputIterator l,
                          size_type n = see below, const hasher& hf = hasher(),
                          const key_equal& eql = key_equal(),
                          const allocator_type& a = allocator_type());
template<container-compatible-range<value_type> R>
  constexpr unordered_map(from_range_t, R&& rg,
                          size_type n = see below, const hasher& hf = hasher(),
                          const key_equal& eql = key_equal(),
                          const allocator_type& a = allocator_type());
constexpr unordered_map(initializer_list<value_type> il,
                        size_type n = see below, const hasher& hf = hasher(),
                        const key_equal& eql = key_equal(),
                        const allocator_type& a = allocator_type());
```

3 *Effects*: Constructs an empty `unordered_map` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. If `n` is not provided, the number of buckets is implementation-defined. Then inserts elements from the range `[f, l)`, `rg`, or `il`, respectively. `max_load_factor()` returns `1.0`.

4 *Complexity*: Average case linear, worst case quadratic.

23.5.3.3 Element access [unord.map.elem]

```
constexpr mapped_type& operator[](const key_type& k);
```

1 *Effects*: Equivalent to: `return try_emplace(k).first->second;`

```
constexpr mapped_type& operator[](key_type&& k);
```

2 *Effects*: Equivalent to: `return try_emplace(std::move(k)).first->second;`

```
template<class K> constexpr mapped_type& operator[](K&& k);
```

3 *Constraints*: The *qualified-id*s `Hash::is_transparent` and `Pred::is_transparent` are valid and denote types.

4 *Effects*: Equivalent to: `return try_emplace(std::forward<K>(k)).first->second;`

```
constexpr mapped_type& at(const key_type& k);
constexpr const mapped_type& at(const key_type& k) const;
```

5 *Returns*: A reference to `x.second`, where `x` is the (unique) element whose key is equivalent to `k`.

6 *Throws*: An exception object of type `out_of_range` if no such element is present.

```
template<class K> constexpr mapped_type&       at(const K& k);
```

```
template<class K> constexpr const mapped_type& at(const K& k) const;
```

7 *Constraints*: The *qualified-id*s `Hash::is_transparent` and `Pred::is_transparent` are valid and denote types.

8 *Preconditions*: The expression `find(k)` is well-formed and has well-defined behavior.

9 *Returns*: A reference to `find(k)->second`.

10 *Throws*: An exception object of type `out_of_range` if `find(k) == end()` is `true`.

23.5.3.4 Modifiers [unord.map.modifiers]

```
template<class P>
  constexpr pair<iterator, bool> insert(P&& obj);
```

1 *Constraints*: `is_constructible_v<value_type, P&&>` is `true`.

2 *Effects*: Equivalent to: `return emplace(std::forward<P>(obj));`

```
template<class P>
  constexpr iterator insert(const_iterator hint, P&& obj);
```

3 *Constraints*: `is_constructible_v<value_type, P&&>` is `true`.

4 *Effects*: Equivalent to: `return emplace_hint(hint, std::forward<P>(obj));`

```
template<class... Args>
  constexpr pair<iterator, bool> try_emplace(const key_type& k, Args&&... args);
template<class... Args>
  constexpr iterator try_emplace(const_iterator hint, const key_type& k, Args&&... args);
```

5 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `unordered_map` from `piecewise_construct`, `forward_as_tuple(k)`, `forward_as_tuple(std::forward<Args>(args)...)`.

6 *Effects*: If the map already contains an element whose key is equivalent to `k`, there is no effect. Otherwise inserts an object of type `value_type` constructed with `piecewise_construct`, `forward_as_tuple(k)`, `forward_as_tuple(std::forward<Args>(args)...)`.

7 *Returns*: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

8 *Complexity*: The same as `emplace` and `emplace_hint`, respectively.

```
template<class... Args>
  constexpr pair<iterator, bool> try_emplace(key_type&& k, Args&&... args);
template<class... Args>
  constexpr iterator try_emplace(const_iterator hint, key_type&& k, Args&&... args);
```

9 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `unordered_map` from `piecewise_construct`, `forward_as_tuple(std::move(k))`, `forward_as_tuple(std::forward<Args>(args)...)`.

10 *Effects*: If the map already contains an element whose key is equivalent to `k`, there is no effect. Otherwise inserts an object of type `value_type` constructed with `piecewise_construct`, `forward_as_tuple(std::move(k))`, `forward_as_tuple(std::forward<Args>(args)...)`.

11 *Returns*: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

12 *Complexity*: The same as `emplace` and `emplace_hint`, respectively.

```
template<class K, class... Args>
  constexpr pair<iterator, bool> try_emplace(K&& k, Args&&... args);
template<class K, class... Args>
  constexpr iterator try_emplace(const_iterator hint, K&& k, Args&&... args);
```

13 *Constraints*: The *qualified-id*s `Hash::is_transparent` and `Pred::is_transparent` are valid and denote types. For the first overload, `is_convertible_v<K&&, const_iterator>` and `is_convertible_v<K&&, iterator>` are both `false`.

14 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `unordered_map` from `piecewise_construct, forward_as_tuple(std::forward<K>(k)), forward_as_tuple(std::forward<Args>(args)...)`.

15 *Effects*: If the map already contains an element whose key is equivalent to `k`, there is no effect. Otherwise, let `h` be `hash_function()(k)`. Constructs an object `u` of type `value_type` with `piecewise_construct, forward_as_tuple(std::forward<K>(k)), forward_as_tuple(std::forward<Args>(args)...)`. If `hash_function()(u.first) != h || contains(u.first)` is `true`, the behavior is undefined. Inserts `u` into `*this`.

16 *Returns*: For the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

17 *Complexity*: The same as `emplace` and `emplace_hint`, respectively.

```
template<class M>
  constexpr pair<iterator, bool> insert_or_assign(const key_type& k, M&& obj);
template<class M>
  constexpr iterator insert_or_assign(const_iterator hint, const key_type& k, M&& obj);
```

18 *Mandates*: `is_assignable_v<mapped_type&, M&&>` is `true`.

19 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `unordered_map` from `k`, `std::forward<M>(obj)`.

20 *Effects*: If the map already contains an element `e` whose key is equivalent to `k`, assigns `std::forward<M>(obj)` to `e.second`. Otherwise inserts an object of type `value_type` constructed with `k`, `std::forward<M>(obj)`.

21 *Returns*: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

22 *Complexity*: The same as `emplace` and `emplace_hint`, respectively.

```
template<class M>
  constexpr pair<iterator, bool> insert_or_assign(key_type&& k, M&& obj);
template<class M>
  constexpr iterator insert_or_assign(const_iterator hint, key_type&& k, M&& obj);
```

23 *Mandates*: `is_assignable_v<mapped_type&, M&&>` is `true`.

24 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `unordered_map` from `std::move(k)`, `std::forward<M>(obj)`.

25 *Effects*: If the map already contains an element `e` whose key is equivalent to `k`, assigns `std::forward<M>(obj)` to `e.second`. Otherwise inserts an object of type `value_type` constructed with `std::move(k)`, `std::forward<M>(obj)`.

26 *Returns*: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

27 *Complexity*: The same as `emplace` and `emplace_hint`, respectively.

```
template<class K, class M>
  constexpr pair<iterator, bool> insert_or_assign(K&& k, M&& obj);
template<class K, class M>
  constexpr iterator insert_or_assign(const_iterator hint, K&& k, M&& obj);
```

28 *Constraints*: The *qualified-id*s `Hash::is_transparent` and `Pred::is_transparent` are valid and denote types.

29 *Mandates*: `is_assignable_v<mapped_type&, M&&>` is `true`.

30 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `unordered_map` from `std::forward<K>(k), std::forward<M>(obj)`.

31 *Effects*: If the map already contains an element `e` whose key is equivalent to `k`, assigns `std::forward<M>(obj)` to `e.second`. Otherwise, let `h` be `hash_function()(k)`. Constructs an object `u` of type `value_type` with `std::forward<K>(k), std::forward<M>(obj)`. If `hash_function()(u.first) != h || contains(u.first)` is `true`, the behavior is undefined. Inserts `u` into `*this`.

32 *Returns*: For the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

33 *Complexity*: The same as `emplace` and `emplace_hint`, respectively.

23.5.3.5 Erasure [unord.map.erasure]

```
template<class K, class T, class H, class P, class A, class Predicate>
  constexpr typename unordered_map<K, T, H, P, A>::size_type
    erase_if(unordered_map<K, T, H, P, A>& c, Predicate pred);
```

1 *Effects*: Equivalent to:

```
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
}
return original_size - c.size();
```

23.5.4 Class template unordered_multimap [unord.multimap]

23.5.4.1 Overview [unord.multimap.overview]

1 An `unordered_multimap` is an unordered associative container that supports equivalent keys (an instance of `unordered_multimap` may contain multiple copies of each key value) and that associates values of another type `mapped_type` with the keys. The `unordered_multimap` class supports forward iterators.

2 An `unordered_multimap` meets all of the requirements of a container (23.2.2.2), of an allocator-aware container (23.2.2.5), and of an unordered associative container (23.2.8). It provides the operations described in the preceding requirements table for equivalent keys; that is, an `unordered_multimap` supports the `a_eq` operations in that table, not the `a_uniq` operations. For an `unordered_multimap<Key, T>` the `key_type` is `Key`, the `mapped_type` is `T`, and the `value_type` is `pair<const Key, T>`.

3 Subclause 23.5.4 only describes operations on `unordered_multimap` that are not described in one of the requirement tables, or for which there is additional semantic information.

4 The types `iterator`, `const_iterator`, `local_iterator`, and `const_local_iterator` meet the constexpr iterator requirements (24.3.1).

```
namespace std {
  template<class Key,
           class T,
           class Hash = hash<Key>,
           class Pred = equal_to<Key>,
           class Allocator = allocator<pair<const Key, T>>>
  class unordered_multimap {
  public:
    // types
    using key_type             = Key;
    using mapped_type          = T;
    using value_type           = pair<const Key, T>;
    using hasher               = Hash;
    using key_equal            = Pred;
    using allocator_type       = Allocator;
    using pointer              = allocator_traits<Allocator>::pointer;
    using const_pointer        = allocator_traits<Allocator>::const_pointer;
    using reference            = value_type&;
    using const_reference      = const value_type&;
    using size_type            = implementation-defined; // see 23.2
    using difference_type      = implementation-defined; // see 23.2

                       Allocator)
      -> unordered_multimap<Key, T, hash<Key>, equal_to<Key>, Allocator>;

  template<class Key, class T, class Allocator>
    unordered_multimap(initializer_list<pair<Key, T>>, Allocator)
      -> unordered_multimap<Key, T, hash<Key>, equal_to<Key>, Allocator>;

  template<class Key, class T, class Hash, class Allocator>
    unordered_multimap(initializer_list<pair<Key, T>>, typename see below::size_type,
                       Hash, Allocator)
      -> unordered_multimap<Key, T, Hash, equal_to<Key>, Allocator>;
}
```

5 A `size_type` parameter type in an `unordered_multimap` deduction guide refers to the `size_type` member type of the type deduced by the deduction guide.

23.5.4.2 Constructors [unord.multimap.cnstr]

```
constexpr unordered_multimap() : unordered_multimap(size_type(see below)) { }
constexpr explicit unordered_multimap(size_type n, const hasher& hf = hasher(),
                                      const key_equal& eql = key_equal(),
                                      const allocator_type& a = allocator_type());
```

1 *Effects*: Constructs an empty `unordered_multimap` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. For the default constructor, the number of buckets is implementation-defined. `max_load_factor()` returns `1.0`.

2 *Complexity*: Constant.

```
template<class InputIterator>
  constexpr unordered_multimap(InputIterator f, InputIterator l,
                               size_type n = see below, const hasher& hf = hasher(),
                               const key_equal& eql = key_equal(),
                               const allocator_type& a = allocator_type());
template<container-compatible-range<value_type> R>
  constexpr unordered_multimap(from_range_t, R&& rg,
                               size_type n = see below, const hasher& hf = hasher(),
                               const key_equal& eql = key_equal(),
                               const allocator_type& a = allocator_type());
```

```
constexpr unordered_multimap(initializer_list<value_type> il,
                             size_type n = see below, const hasher& hf = hasher(),
                             const key_equal& eql = key_equal(),
                             const allocator_type& a = allocator_type());
```

3 *Effects*: Constructs an empty `unordered_multimap` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. If `n` is not provided, the number of buckets is implementation-defined. Then inserts elements from the range `[f,l)`, `rg`, or `il`, respectively. `max_load_factor()` returns `1.0`.

4 *Complexity*: Average case linear, worst case quadratic.

23.5.4.3 Modifiers [unord.multimap.modifiers]

```
template<class P>
  constexpr iterator insert(P&& obj);
```

1 *Constraints*: `is_constructible_v<value_type, P&&>` is `true`.

2 *Effects*: Equivalent to: `return emplace(std::forward<P>(obj));`

```
template<class P>
  constexpr iterator insert(const_iterator hint, P&& obj);
```

3 *Constraints*: `is_constructible_v<value_type, P&&>` is `true`.

4 *Effects*: Equivalent to: `return emplace_hint(hint, std::forward<P>(obj));`

23.5.4.4 Erasure [unord.multimap.erasure]

```
template<class K, class T, class H, class P, class A, class Predicate>
  constexpr typename unordered_multimap<K, T, H, P, A>::size_type
    erase_if(unordered_multimap<K, T, H, P, A>& c, Predicate pred);
```

1 *Effects*: Equivalent to:

```
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
}
return original_size - c.size();
```

23.5.5 Header <unordered_set> synopsis [unord.set.syn]

  }
}
```

23.5.6 Class template unordered_set [unord.set]

23.5.6.1 Overview [unord.set.overview]

1 An `unordered_set` is an unordered associative container that supports unique keys (an `unordered_set` contains at most one of each key value) and in which the elements' keys are the elements themselves. The `unordered_set` class supports forward iterators.

2 An `unordered_set` meets all of the requirements of a container (23.2.2.2), of an allocator-aware container (23.2.2.5), and of an unordered associative container (23.2.8). It provides the operations described in the preceding requirements table for unique keys; that is, an `unordered_set` supports the `a_uniq` operations in that table, not the `a_eq` operations. For an `unordered_set<Key>` the `key_type` and the `value_type` are both `Key`. The `iterator` and `const_iterator` types are both constant iterator types. It is unspecified whether they are the same type.

3 Subclause 23.5.6 only describes operations on `unordered_set` that are not described in one of the requirement tables, or for which there is additional semantic information.

4 The types `iterator`, `const_iterator`, `local_iterator`, and `const_local_iterator` meet the constexpr iterator requirements (24.3.1).

```
namespace std {
  template<class Key,
           class Hash = hash<Key>,
           class Pred = equal_to<Key>,
           class Allocator = allocator<Key>>
  class unordered_set {
```

```
public:
  // types

5 A `size_type` parameter type in an `unordered_set` deduction guide refers to the `size_type` member type of the type deduced by the deduction guide.

23.5.6.2 Constructors [unord.set.cnstr]

```
constexpr unordered_set() : unordered_set(size_type(see below)) { }
constexpr explicit unordered_set(size_type n, const hasher& hf = hasher(),
                                 const key_equal& eql = key_equal(),
                                 const allocator_type& a = allocator_type());
```

1 *Effects*: Constructs an empty `unordered_set` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. For the default constructor, the number of buckets is implementation-defined. `max_load_factor()` returns `1.0`.

2 *Complexity*: Constant.

```
template<class InputIterator>
  constexpr unordered_set(InputIterator f, InputIterator l,
                          size_type n = see below, const hasher& hf = hasher(),
                          const key_equal& eql = key_equal(),
                          const allocator_type& a = allocator_type());
template<container-compatible-range<value_type> R>
  constexpr unordered_multiset(from_range_t, R&& rg,
                               size_type n = see below, const hasher& hf = hasher(),
                               const key_equal& eql = key_equal(),
                               const allocator_type& a = allocator_type());
constexpr unordered_set(initializer_list<value_type> il,
                        size_type n = see below, const hasher& hf = hasher(),
                        const key_equal& eql = key_equal(),
                        const allocator_type& a = allocator_type());
```

3 *Effects*: Constructs an empty `unordered_set` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. If `n` is not provided, the number of buckets is implementation-defined. Then inserts elements from the range $[$`f`, `l`$)$, `rg`, or `il`, respectively. `max_load_factor()` returns `1.0`.

4 *Complexity*: Average case linear, worst case quadratic.

23.5.6.3 Erasure [unord.set.erasure]

```
template<class K, class H, class P, class A, class Predicate>
  constexpr typename unordered_set<K, H, P, A>::size_type
    erase_if(unordered_set<K, H, P, A>& c, Predicate pred);
```

1 *Effects*: Equivalent to:

```
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
}
return original_size - c.size();
```

23.5.6.4 Modifiers [unord.set.modifiers]

```
template<class K> constexpr pair<iterator, bool> insert(K&& obj);
template<class K> constexpr iterator insert(const_iterator hint, K&& obj);
```

1 *Constraints*: The *qualified-id*s `Hash::is_transparent` and `Pred::is_transparent` are valid and denote types. For the second overload, `is_convertible_v<K&&, const_iterator>` and `is_convertible_v<K&&, iterator>` are both `false`.

2 *Preconditions*: `value_type` is *Cpp17EmplaceConstructible* into `unordered_set` from `std::forward<K>(obj)`.

3 *Effects*: If the set already contains an element that is equivalent to `obj`, there is no effect. Otherwise, let `h` be `hash_function()(obj)`. Constructs an object `u` of type `value_type` with `std::forward<K>(obj)`. If `hash_function()(u) != h || contains(u)` is `true`, the behavior is undefined. Inserts `u` into `*this`.

4 *Returns*: For the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the set element that is equivalent to `obj`.

5 *Complexity*: Average case constant, worst case linear.

23.5.7 Class template `unordered_multiset` [unord.multiset]

23.5.7.1 Overview [unord.multiset.overview]

1 An `unordered_multiset` is an unordered associative container that supports equivalent keys (an instance of `unordered_multiset` may contain multiple copies of the same key value) and in which each element's key is the element itself. The `unordered_multiset` class supports forward iterators.

[2] An `unordered_multiset` meets all of the requirements of a container (23.2.2.2), of an allocator-aware container (23.2.2.5), and of an unordered associative container (23.2.8). It provides the operations described in the preceding requirements table for equivalent keys; that is, an `unordered_multiset` supports the `a_eq` operations in that table, not the `a_uniq` operations. For an `unordered_multiset<Key>` the `key_type` and the `value_type` are both `Key`. The `iterator` and `const_iterator` types are both constant iterator types. It is unspecified whether they are the same type.

[3] Subclause 23.5.7 only describes operations on `unordered_multiset` that are not described in one of the requirement tables, or for which there is additional semantic information.

[4] The types `iterator`, `const_iterator`, `local_iterator`, and `const_local_iterator` meet the constexpr iterator requirements (24.3.1).

```
namespace std {
  template<class Key,
           class Hash = hash<Key>,
           class Pred = equal_to<Key>,
           class Allocator = allocator<Key>>
  class unordered_multiset {
  public:
    // types
    using key_type             = Key;
    using value_type           = Key;
    using hasher               = Hash;
    using key_equal            = Pred;
    using allocator_type       = Allocator;
    using pointer              = allocator_traits<Allocator>::pointer;
    using const_pointer        = allocator_traits<Allocator>::const_pointer;
    using reference            = value_type&;
    using const_reference      = const value_type&;
    using size_type            = implementation-defined; // see 23.2
    using difference_type      = implementation-defined; // see 23.2

    using iterator             = implementation-defined; // see 23.2

      -> unordered_multiset<T, hash<T>, equal_to<T>, Allocator>;

  template<class T, class Hash, class Allocator>
    unordered_multiset(initializer_list<T>, typename see below::size_type, Hash, Allocator)
      -> unordered_multiset<T, Hash, equal_to<T>, Allocator>;
}
```

[5] A `size_type` parameter type in an `unordered_multiset` deduction guide refers to the `size_type` member type of the type deduced by the deduction guide.

23.5.7.2 Constructors [unord.multiset.cnstr]

```
constexpr unordered_multiset() : unordered_multiset(size_type(see below)) { }
constexpr explicit unordered_multiset(size_type n, const hasher& hf = hasher(),
                                      const key_equal& eql = key_equal(),
                                      const allocator_type& a = allocator_type());
```

1 *Effects*: Constructs an empty `unordered_multiset` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. For the default constructor, the number of buckets is implementation-defined. `max_load_factor()` returns `1.0`.

2 *Complexity*: Constant.

```
template<class InputIterator>
  constexpr unordered_multiset(InputIterator f, InputIterator l,
                               size_type n = see below, const hasher& hf = hasher(),
                               const key_equal& eql = key_equal(),
                               const allocator_type& a = allocator_type());
template<container-compatible-range<value_type> R>
  constexpr unordered_multiset(from_range_t, R&& rg,
                               size_type n = see below, const hasher& hf = hasher(),
                               const key_equal& eql = key_equal(),
                               const allocator_type& a = allocator_type());
constexpr unordered_multiset(initializer_list<value_type> il,
                             size_type n = see below, const hasher& hf = hasher(),
                             const key_equal& eql = key_equal(),
                             const allocator_type& a = allocator_type());
```

3 *Effects*: Constructs an empty `unordered_multiset` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. If `n` is not provided, the number of buckets is implementation-defined. Then inserts elements from the range `[f,l)`, `rg`, or `il`, respectively. `max_load_factor()` returns `1.0`.

4 *Complexity*: Average case linear, worst case quadratic.

23.5.7.3 Erasure [unord.multiset.erasure]

```
template<class K, class H, class P, class A, class Predicate>
  constexpr typename unordered_multiset<K, H, P, A>::size_type
    erase_if(unordered_multiset<K, H, P, A>& c, Predicate pred);
```

1 *Effects*: Equivalent to:

```
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
}
return original_size - c.size();
```

23.6 Container adaptors [container.adaptors]

23.6.1 General [container.adaptors.general]

1 The headers `<queue>` (23.6.2), `<stack>` (23.6.5), `<flat_map>` (23.6.7), and `<flat_set>` (23.6.10) define the container adaptors `queue` and `priority_queue`, `stack`, `flat_map` and `flat_multimap`, and `flat_set` and `flat_multiset`, respectively.

2 Each container adaptor takes one or more template parameters named `Container`, `KeyContainer`, or `MappedContainer` that denote the types of containers that the container adaptor adapts. Each container adaptor has at least one constructor that takes a reference argument to one or more such template parameters. For each constructor reference argument to a container `C`, the constructor copies the container into the container adaptor. If `C` takes an allocator, then a compatible allocator may be passed in to the adaptor's constructor. Otherwise, normal copy or move construction is used for the container argument. For the

container adaptors that take a single container template parameter `Container`, the first template parameter `T` of the container adaptor shall denote the same type as `Container::value_type`.

3 For container adaptors, no `swap` function throws an exception unless that exception is thrown by the swap of the adaptor's `Container`, `KeyContainer`, `MappedContainer`, or `Compare` object (if any).

4 A constructor template of a container adaptor shall not participate in overload resolution if it has an `InputIterator` template parameter and a type that does not qualify as an input iterator is deduced for that parameter.

5 For container adaptors that have them, the `insert`, `emplace`, and `erase` members affect the validity of iterators, references, and pointers to the adaptor's container(s) in the same way that the containers' respective `insert`, `emplace`, and `erase` members do.

[*Example 1*: A call to `flat_map<Key, T>::insert` can invalidate all iterators to the `flat_map`. — *end example*]

6 A deduction guide for a container adaptor shall not participate in overload resolution if any of the following are true:

(6.1) — It has an `InputIterator` template parameter and a type that does not qualify as an input iterator is deduced for that parameter.

(6.2) — It has a `Compare` template parameter and a type that qualifies as an allocator is deduced for that parameter.

(6.3) — It has a `Container`, `KeyContainer`, or `MappedContainer` template parameter and a type that qualifies as an allocator is deduced for that parameter.

(6.4) — It has no `Container`, `KeyContainer`, or `MappedContainer` template parameter, and it has an `Allocator` template parameter, and a type that does not qualify as an allocator is deduced for that parameter.

(6.5) — It has both `Container` and `Allocator` template parameters, and `uses_allocator_v<Container, Allocator>` is `false`.

(6.6) — It has both `KeyContainer` and `Allocator` template parameters, and `uses_allocator_v<KeyContainer, Allocator>` is `false`.

(6.7) — It has both `KeyContainer` and `Compare` template parameters, and

```
is_invocable_v<const Compare&,
               const typename KeyContainer::value_type&,
               const typename KeyContainer::value_type&>
```

is not a valid expression or is `false`.

(6.8) — It has both `MappedContainer` and `Allocator` template parameters, and `uses_allocator_v<MappedContainer, Allocator>` is `false`.

7 The exposition-only alias template *`iter-value-type`* defined in 23.3.1 and the exposition-only alias templates *`iter-key-type`*, *`iter-mapped-type`*, *`range-key-type`*, and *`range-mapped-type`* defined in 23.4.1 may appear in deduction guides for container adaptors.

8 The following exposition-only alias template may appear in deduction guides for container adaptors:

```
template<class Allocator, class T>
  using alloc-rebind = allocator_traits<Allocator>::template rebind_alloc<T>;    // exposition only
```

23.6.2 Header <queue> synopsis [queue.syn]

23.6.3 Class template queue [queue]

23.6.3.1 Definition [queue.defn]

1 Any sequence container supporting operations `front()`, `back()`, `push_back()` and `pop_front()` can be used to instantiate `queue`. In particular, `list` (23.3.11) and `deque` (23.3.5) can be used.

```
namespace std {
  template<class T, class Container = deque<T>>
  class queue {
  public:
    using value_type      = Container::value_type;
    using reference       = Container::reference;
    using const_reference = Container::const_reference;
    using size_type       = Container::size_type;
    using container_type  = Container;

  protected:
    Container c;

  public:
    constexpr queue() : queue(Container()) {}
    constexpr explicit queue(const Container&);
```

```
    constexpr explicit queue(Container&&);
    template<class InputIterator> constexpr queue(InputIterator first, InputIterator last);
    template<container-compatible-range<T> R> constexpr queue(from_range_t, R&& rg);
    template<class Alloc> constexpr explicit queue(const Alloc&);
    template<class Alloc> constexpr queue(const Container&, const Alloc&);
    template<class Alloc> constexpr queue(Container&&, const Alloc&);
    template<class Alloc> constexpr queue(const queue&, const Alloc&);
    template<class Alloc> constexpr queue(queue&&, const Alloc&);
    template<class InputIterator, class Alloc>
      constexpr queue(InputIterator first, InputIterator last, const Alloc&);
    template<container-compatible-range<T> R, class Alloc>
      constexpr queue(from_range_t, R&& rg, const Alloc&);

    constexpr bool              empty() const     { return c.empty(); }
    constexpr size_type         size()  const     { return c.size(); }
    constexpr reference         front()           { return c.front(); }
    constexpr const_reference   front() const     { return c.front(); }
    constexpr reference         back()            { return c.back(); }
    constexpr const_reference   back() const      { return c.back(); }
    constexpr void push(const value_type& x)      { c.push_back(x); }
    constexpr void push(value_type&& x)           { c.push_back(std::move(x)); }
    template<container-compatible-range<T> R> constexpr void push_range(R&& rg);
    template<class... Args>
      constexpr decltype(auto) emplace(Args&&... args)
        { return c.emplace_back(std::forward<Args>(args)...); }
    constexpr void pop()                          { c.pop_front(); }
    constexpr void swap(queue& q) noexcept(is_nothrow_swappable_v<Container>)
      { using std::swap; swap(c, q.c); }
  };

  template<class Container>
    queue(Container) -> queue<typename Container::value_type, Container>;

  template<class InputIterator>
    queue(InputIterator, InputIterator) -> queue<iter-value-type<InputIterator>>;

  template<ranges::input_range R>
    queue(from_range_t, R&&) -> queue<ranges::range_value_t<R>>;

  template<class Container, class Allocator>
    queue(Container, Allocator) -> queue<typename Container::value_type, Container>;

  template<class InputIterator, class Allocator>
    queue(InputIterator, InputIterator, Allocator)
      -> queue<iter-value-type<InputIterator>, deque<iter-value-type<InputIterator>,
               Allocator>>;

  template<ranges::input_range R, class Allocator>
    queue(from_range_t, R&&, Allocator)
      -> queue<ranges::range_value_t<R>, deque<ranges::range_value_t<R>, Allocator>>;

  template<class T, class Container, class Alloc>
    struct uses_allocator<queue<T, Container>, Alloc>
      : uses_allocator<Container, Alloc>::type { };
}
```

23.6.3.2 Constructors [queue.cons]

```
constexpr explicit queue(const Container& cont);
```

1 *Effects*: Initializes `c` with `cont`.

```
constexpr explicit queue(Container&& cont);
```

2 *Effects*: Initializes `c` with `std::move(cont)`.

```
template<class InputIterator>
  constexpr queue(InputIterator first, InputIterator last);
```

3 *Effects*: Initializes `c` with `first` as the first argument and `last` as the second argument.

```
template<container-compatible-range<T> R>
  constexpr queue(from_range_t, R&& rg);
```

4 *Effects*: Initializes `c` with `ranges::to<Container>(std::forward<R>(rg))`.

23.6.3.3 Constructors with allocators [queue.cons.alloc]

1 If `uses_allocator_v<container_type, Alloc>` is `false` the constructors in this subclause shall not participate in overload resolution.

```
template<class Alloc> constexpr explicit queue(const Alloc& a);
```

2 *Effects*: Initializes `c` with `a`.

```
template<class Alloc> constexpr queue(const container_type& cont, const Alloc& a);
```

3 *Effects*: Initializes `c` with `cont` as the first argument and `a` as the second argument.

```
template<class Alloc> constexpr queue(container_type&& cont, const Alloc& a);
```

4 *Effects*: Initializes `c` with `std::move(cont)` as the first argument and `a` as the second argument.

```
template<class Alloc> constexpr queue(const queue& q, const Alloc& a);
```

5 *Effects*: Initializes `c` with `q.c` as the first argument and `a` as the second argument.

```
template<class Alloc> constexpr queue(queue&& q, const Alloc& a);
```

6 *Effects*: Initializes `c` with `std::move(q.c)` as the first argument and `a` as the second argument.

```
template<class InputIterator, class Alloc>
  constexpr queue(InputIterator first, InputIterator last, const Alloc& alloc);
```

7 *Effects*: Initializes `c` with `first` as the first argument, `last` as the second argument, and `alloc` as the third argument.

```
template<container-compatible-range<T> R, class Alloc>
  constexpr queue(from_range_t, R&& rg, const Alloc& a);
```

8 *Effects*: Initializes `c` with `ranges::to<Container>(std::forward<R>(rg), a)`.

23.6.3.4 Modifiers [queue.mod]

```
template<container-compatible-range<T> R>
  constexpr void push_range(R&& rg);
```

1 *Effects*: Equivalent to `c.append_range(std::forward<R>(rg))` if that is a valid expression, otherwise `ranges::copy(rg, back_inserter(c))`.

23.6.3.5 Operators [queue.ops]

```
template<class T, class Container>
  constexpr bool operator==(const queue<T, Container>& x, const queue<T, Container>& y);
```

1 *Returns*: `x.c == y.c`.

```
template<class T, class Container>
  constexpr bool operator!=(const queue<T, Container>& x,  const queue<T, Container>& y);
```

2 *Returns*: `x.c != y.c`.

```
template<class T, class Container>
  constexpr bool operator< (const queue<T, Container>& x, const queue<T, Container>& y);
```

3 *Returns*: `x.c < y.c`.

```
template<class T, class Container>
  constexpr bool operator> (const queue<T, Container>& x, const queue<T, Container>& y);
```

4 *Returns*: `x.c > y.c`.

```
template<class T, class Container>
  constexpr bool operator<=(const queue<T, Container>& x, const queue<T, Container>& y);
```

5 *Returns*: `x.c <= y.c`.

```
template<class T, class Container>
  constexpr bool operator>=(const queue<T, Container>& x, const queue<T, Container>& y);
```

6 *Returns*: `x.c >= y.c`.

```
template<class T, three_way_comparable Container>
  constexpr compare_three_way_result_t<Container>
    operator<=>(const queue<T, Container>& x, const queue<T, Container>& y);
```

7 *Returns*: `x.c <=> y.c`.

23.6.3.6 Specialized algorithms [queue.special]

```
template<class T, class Container>
  constexpr void swap(queue<T, Container>& x, queue<T, Container>& y)
    noexcept(noexcept(x.swap(y)));
```

1 *Constraints*: `is_swappable_v<Container>` is `true`.

2 *Effects*: As if by `x.swap(y)`.

23.6.4 Class template `priority_queue` [priority.queue]

23.6.4.1 Overview [priqueue.overview]

1 Any sequence container with random access iterator and supporting operations `front()`, `push_back()` and `pop_back()` can be used to instantiate `priority_queue`. In particular, `vector` (23.3.13) and `deque` (23.3.5) can be used. Instantiating `priority_queue` also involves supplying a function or function object for making priority comparisons; the library assumes that the function or function object defines a strict weak ordering (26.8).

```
namespace std {
  template<class T, class Container = vector<T>,
           class Compare = less<typename Container::value_type>>
  class priority_queue {
  public:
    using value_type      = Container::value_type;
    using reference       = Container::reference;
    using const_reference = Container::const_reference;
    using size_type       = Container::size_type;
    using container_type  = Container;
    using value_compare   = Compare;

  protected:
    Container c;
    Compare comp;

  public:
    constexpr priority_queue() : priority_queue(Compare()) {}
    constexpr explicit priority_queue(const Compare& x) : priority_queue(x, Container()) {}
    constexpr priority_queue(const Compare& x, const Container&);
    constexpr priority_queue(const Compare& x, Container&&);
    template<class InputIterator>
      constexpr priority_queue(InputIterator first, InputIterator last,
                               const Compare& x = Compare());
    template<class InputIterator>
      constexpr priority_queue(InputIterator first, InputIterator last, const Compare& x,
                               const Container&);
    template<class InputIterator>
      constexpr priority_queue(InputIterator first, InputIterator last, const Compare& x,
                               Container&&);
    template<container-compatible-range<T> R>
      constexpr priority_queue(from_range_t, R&& rg, const Compare& x = Compare());
    template<class Alloc> constexpr explicit priority_queue(const Alloc&);
```

```
  template<class Alloc> constexpr priority_queue(const Compare&, const Alloc&);
  template<class Alloc>
    constexpr priority_queue(const Compare&, const Container&, const Alloc&);
  template<class Alloc> constexpr priority_queue(const Compare&, Container&&, const Alloc&);
  template<class Alloc> constexpr priority_queue(const priority_queue&, const Alloc&);
  template<class Alloc> constexpr priority_queue(priority_queue&&, const Alloc&);
  template<class InputIterator, class Alloc>
    constexpr priority_queue(InputIterator, InputIterator, const Alloc&);
  template<class InputIterator, class Alloc>
    constexpr priority_queue(InputIterator, InputIterator, const Compare&, const Alloc&);
  template<class InputIterator, class Alloc>
    constexpr priority_queue(InputIterator, InputIterator, const Compare&, const Container&,
                             const Alloc&);
  template<class InputIterator, class Alloc>
    constexpr priority_queue(InputIterator, InputIterator, const Compare&, Container&&,
                             const Alloc&);
  template<container-compatible-range<T> R, class Alloc>
    constexpr priority_queue(from_range_t, R&& rg, const Compare&, const Alloc&);
  template<container-compatible-range<T> R, class Alloc>
    constexpr priority_queue(from_range_t, R&& rg, const Alloc&);

  constexpr bool            empty() const { return c.empty(); }
  constexpr size_type       size()  const { return c.size(); }

  // no equality is provided

  template<class T, class Container, class Compare, class Alloc>
    struct uses_allocator<priority_queue<T, Container, Compare>, Alloc>
      : uses_allocator<Container, Alloc>::type { };
}
```

23.6.4.2 Constructors [priqueue.cons]

```
constexpr priority_queue(const Compare& x, const Container& y);
constexpr priority_queue(const Compare& x, Container&& y);
```

1 *Preconditions*: `x` defines a strict weak ordering (26.8).

2 *Effects*: Initializes `comp` with `x` and `c` with `y` (copy constructing or move constructing as appropriate); calls `make_heap(c.begin(), c.end(), comp)`.

```
template<class InputIterator>
  constexpr priority_queue(InputIterator first, InputIterator last, const Compare& x = Compare());
```

3 *Preconditions*: `x` defines a strict weak ordering (26.8).

4 *Effects*: Initializes `c` with `first` as the first argument and `last` as the second argument, and initializes `comp` with `x`; then calls `make_heap(c.begin(), c.end(), comp)`.

```
template<class InputIterator>
  constexpr priority_queue(InputIterator first, InputIterator last, const Compare& x,
                           const Container& y);
template<class InputIterator>
  constexpr priority_queue(InputIterator first, InputIterator last, const Compare& x,
                           Container&& y);
```

5 *Preconditions*: `x` defines a strict weak ordering (26.8).

6 *Effects*: Initializes `comp` with `x` and `c` with `y` (copy constructing or move constructing as appropriate); calls `c.insert(c.end(), first, last)`; and finally calls `make_heap(c.begin(), c.end(), comp)`.

```
template<container-compatible-range<T> R>
  constexpr priority_queue(from_range_t, R&& rg, const Compare& x = Compare());
```

7 *Preconditions*: `x` defines a strict weak ordering (26.8).

8 *Effects*: Initializes `comp` with `x` and `c` with `ranges::to<Container>(std::forward<R>(rg))` and finally calls `make_heap(c.begin(), c.end(), comp)`.

23.6.4.3 Constructors with allocators [priqueue.cons.alloc]

1 If `uses_allocator_v<container_type, Alloc>` is `false` the constructors in this subclause shall not participate in overload resolution.

```
template<class Alloc> constexpr explicit priority_queue(const Alloc& a);
```

2 *Effects*: Initializes `c` with `a` and value-initializes `comp`.

```
template<class Alloc> constexpr priority_queue(const Compare& compare, const Alloc& a);
```

3 *Effects*: Initializes `c` with `a` and initializes `comp` with `compare`.

```
template<class Alloc>
  constexpr priority_queue(const Compare& compare, const Container& cont, const Alloc& a);
```

4 *Effects*: Initializes `c` with `cont` as the first argument and `a` as the second argument, and initializes `comp` with `compare`; calls `make_heap(c.begin(), c.end(), comp)`.

```
template<class Alloc>
  constexpr priority_queue(const Compare& compare, Container&& cont, const Alloc& a);
```

5 *Effects*: Initializes `c` with `std::move(cont)` as the first argument and `a` as the second argument, and initializes `comp` with `compare`; calls `make_heap(c.begin(), c.end(), comp)`.

```
template<class Alloc> constexpr priority_queue(const priority_queue& q, const Alloc& a);
```

6 *Effects*: Initializes `c` with `q.c` as the first argument and `a` as the second argument, and initializes `comp` with `q.comp`.

```
template<class Alloc> constexpr priority_queue(priority_queue&& q, const Alloc& a);
```

7 *Effects*: Initializes `c` with `std::move(q.c)` as the first argument and `a` as the second argument, and initializes `comp` with `std::move(q.comp)`.

```
template<class InputIterator, class Alloc>
  constexpr priority_queue(InputIterator first, InputIterator last, const Alloc& a);
```

8 *Effects*: Initializes `c` with `first` as the first argument, `last` as the second argument, and `a` as the third argument, and value-initializes `comp`; calls `make_heap(c.begin(), c.end(), comp)`.

```
template<class InputIterator, class Alloc>
  constexpr priority_queue(InputIterator first, InputIterator last,
                           const Compare& compare, const Alloc& a);
```

9 *Effects*: Initializes `c` with `first` as the first argument, `last` as the second argument, and `a` as the third argument, and initializes `comp` with `compare`; calls `make_heap(c.begin(), c.end(), comp)`.

```
template<class InputIterator, class Alloc>
  constexpr priority_queue(InputIterator first, InputIterator last, const Compare& compare,
                           const Container& cont, const Alloc& a);
```

10 *Effects*: Initializes `c` with `cont` as the first argument and `a` as the second argument, and initializes `comp` with `compare`; calls `c.insert(c.end(), first, last)`; and finally calls `make_heap(c.begin(), c.end(), comp)`.

```
template<class InputIterator, class Alloc>
  constexpr priority_queue(InputIterator first, InputIterator last, const Compare& compare,
                           Container&& cont, const Alloc& a);
```

11 *Effects*: Initializes `c` with `std::move(cont)` as the first argument and `a` as the second argument, and initializes `comp` with `compare`; calls `c.insert(c.end(), first, last)`; and finally calls `make_heap(c.begin(), c.end(), comp)`.

```
template<container-compatible-range<T> R, class Alloc>
  constexpr priority_queue(from_range_t, R&& rg, const Compare& compare, const Alloc& a);
```

12 *Effects*: Initializes `comp` with `compare` and `c` with `ranges::to<Container>(std::forward<R>(rg), a)`; calls `make_heap(c.begin(), c.end(), comp)`.

```
template<container-compatible-range<T> R, class Alloc>
  constexpr priority_queue(from_range_t, R&& rg, const Alloc& a);
```

13 *Effects*: Initializes `c` with `ranges::to<Container>(std::forward<R>(rg), a)` and value-initializes `comp`; calls `make_heap(c.begin(), c.end(), comp)`.

23.6.4.4 Members [priqueue.members]

```
constexpr void push(const value_type& x);
```

1 *Effects*: As if by:

```
c.push_back(x);
push_heap(c.begin(), c.end(), comp);
```

```
constexpr void push(value_type&& x);
```

2 *Effects*: As if by:

```
c.push_back(std::move(x));
push_heap(c.begin(), c.end(), comp);
```

```
template<container-compatible-range<T> R>
  constexpr void push_range(R&& rg);
```

3 *Effects*: Inserts all elements of `rg` in `c` via `c.append_range(std::forward<R>(rg))` if that is a valid expression, or `ranges::copy(rg, back_inserter(c))` otherwise. Then restores the heap property as if by `make_heap(c.begin(), c.end(), comp)`.

4 *Postconditions*: `is_heap(c.begin(), c.end(), comp)` is `true`.

```
template<class... Args> constexpr void emplace(Args&&... args);
```

5 *Effects*: As if by:

```
c.emplace_back(std::forward<Args>(args)...);
push_heap(c.begin(), c.end(), comp);
```

```
constexpr void pop();
```

6 *Effects*: As if by:

```
pop_heap(c.begin(), c.end(), comp);
c.pop_back();
```

23.6.4.5 Specialized algorithms [priqueue.special]

```
template<class T, class Container, class Compare>
  constexpr void swap(priority_queue<T, Container, Compare>& x,
                      priority_queue<T, Container, Compare>& y) noexcept(noexcept(x.swap(y)));
```

1 *Constraints*: `is_swappable_v<Container>` is `true` and `is_swappable_v<Compare>` is `true`.

2 *Effects*: As if by `x.swap(y)`.

23.6.5 Header <stack> synopsis [stack.syn]

```
#include <compare>             // see 17.12.1
#include <initializer_list>    // see 17.11.2

}
```

23.6.6 Class template stack [stack]

23.6.6.1 General [stack.general]

1 Any sequence container supporting operations `back()`, `push_back()` and `pop_back()` can be used to instantiate `stack`. In particular, `vector` (23.3.13), `list` (23.3.11) and `deque` (23.3.5) can be used.

23.6.6.2 Definition [stack.defn]

```
namespace std {
  template<class T, class Container = deque<T>>
  class stack {
  public:
    using value_type      = Container::value_type;
    using reference       = Container::reference;
    using const_reference = Container::const_reference;
    using size_type       = Container::size_type;
    using container_type  = Container;

  protected:
    Container c;

  public:
    constexpr stack() : stack(Container()) {}
    constexpr explicit stack(const Container&);
    constexpr explicit stack(Container&&);
    template<class InputIterator> constexpr stack(InputIterator first, InputIterator last);
    template<container-compatible-range<T> R>
      constexpr stack(from_range_t, R&& rg);
    template<class Alloc> constexpr explicit stack(const Alloc&);
    template<class Alloc> constexpr stack(const Container&, const Alloc&);
    template<class Alloc> constexpr stack(Container&&, const Alloc&);
    template<class Alloc> constexpr stack(const stack&, const Alloc&);
    template<class Alloc> constexpr stack(stack&&, const Alloc&);
    template<class InputIterator, class Alloc>
      constexpr stack(InputIterator first, InputIterator last, const Alloc&);
    template<container-compatible-range<T> R, class Alloc>
      constexpr stack(from_range_t, R&& rg, const Alloc&);

    constexpr bool              empty() const     { return c.empty(); }
    constexpr size_type         size()  const     { return c.size(); }
    constexpr reference         top()             { return c.back(); }
    constexpr const_reference   top()   const     { return c.back(); }
    constexpr void push(const value_type& x)      { c.push_back(x); }
    constexpr void push(value_type&& x)           { c.push_back(std::move(x)); }
    template<container-compatible-range<T> R>
      constexpr void push_range(R&& rg);
    template<class... Args>
      constexpr decltype(auto) emplace(Args&&... args)
        { return c.emplace_back(std::forward<Args>(args)...); }
    constexpr void pop()                          { c.pop_back(); }
    constexpr void swap(stack& s) noexcept(is_nothrow_swappable_v<Container>)
      { using std::swap; swap(c, s.c); }
  };

  template<class Container>
    stack(Container) -> stack<typename Container::value_type, Container>;
```

```
  template<class InputIterator>
    stack(InputIterator, InputIterator) -> stack<iter-value-type<InputIterator>>;

  template<ranges::input_range R>
    stack(from_range_t, R&&) -> stack<ranges::range_value_t<R>>;

  template<class Container, class Allocator>
    stack(Container, Allocator) -> stack<typename Container::value_type, Container>;

  template<class InputIterator, class Allocator>
    stack(InputIterator, InputIterator, Allocator)
      -> stack<iter-value-type<InputIterator>, deque<iter-value-type<InputIterator>,
               Allocator>>;

  template<ranges::input_range R, class Allocator>
    stack(from_range_t, R&&, Allocator)
      -> stack<ranges::range_value_t<R>, deque<ranges::range_value_t<R>, Allocator>>;

  template<class T, class Container, class Alloc>
    struct uses_allocator<stack<T, Container>, Alloc>
      : uses_allocator<Container, Alloc>::type { };
}
```

23.6.6.3 Constructors [stack.cons]

```
constexpr explicit stack(const Container& cont);
```

1 *Effects*: Initializes `c` with `cont`.

```
constexpr explicit stack(Container&& cont);
```

2 *Effects*: Initializes `c` with `std::move(cont)`.

```
template<class InputIterator>
  constexpr stack(InputIterator first, InputIterator last);
```

3 *Effects*: Initializes `c` with `first` as the first argument and `last` as the second argument.

```
template<container-compatible-range<T> R>
  constexpr stack(from_range_t, R&& rg);
```

4 *Effects*: Initializes `c` with `ranges::to<Container>(std::forward<R>(rg))`.

23.6.6.4 Constructors with allocators [stack.cons.alloc]

1 If `uses_allocator_v<container_type, Alloc>` is `false` the constructors in this subclause shall not participate in overload resolution.

```
template<class Alloc> constexpr explicit stack(const Alloc& a);
```

2 *Effects*: Initializes `c` with `a`.

```
template<class Alloc> constexpr stack(const container_type& cont, const Alloc& a);
```

3 *Effects*: Initializes `c` with `cont` as the first argument and `a` as the second argument.

```
template<class Alloc> constexpr stack(container_type&& cont, const Alloc& a);
```

4 *Effects*: Initializes `c` with `std::move(cont)` as the first argument and `a` as the second argument.

```
template<class Alloc> constexpr stack(const stack& s, const Alloc& a);
```

5 *Effects*: Initializes `c` with `s.c` as the first argument and `a` as the second argument.

```
template<class Alloc> constexpr stack(stack&& s, const Alloc& a);
```

6 *Effects*: Initializes `c` with `std::move(s.c)` as the first argument and `a` as the second argument.

```
template<class InputIterator, class Alloc>
  constexpr stack(InputIterator first, InputIterator last, const Alloc& alloc);
```

7 *Effects*: Initializes `c` with `first` as the first argument, `last` as the second argument, and `alloc` as the third argument.

```
template<container-compatible-range<T> R, class Alloc>
  constexpr stack(from_range_t, R&& rg, const Alloc& a);
```

8 *Effects*: Initializes `c` with `ranges::to<Container>(std::forward<R>(rg), a)`.

23.6.6.5 Modifiers [stack.mod]

```
template<container-compatible-range<T> R>
  constexpr void push_range(R&& rg);
```

1 *Effects*: Equivalent to `c.append_range(std::forward<R>(rg))` if that is a valid expression, otherwise `ranges::copy(rg, back_inserter(c))`.

23.6.6.6 Operators [stack.ops]

```
template<class T, class Container>
  constexpr bool operator==(const stack<T, Container>& x, const stack<T, Container>& y);
```

1 *Returns*: `x.c == y.c`.

```
template<class T, class Container>
  constexpr bool operator!=(const stack<T, Container>& x, const stack<T, Container>& y);
```

2 *Returns*: `x.c != y.c`.

```
template<class T, class Container>
  constexpr bool operator< (const stack<T, Container>& x, const stack<T, Container>& y);
```

3 *Returns*: `x.c < y.c`.

```
template<class T, class Container>
  constexpr bool operator> (const stack<T, Container>& x, const stack<T, Container>& y);
```

4 *Returns*: `x.c > y.c`.

```
template<class T, class Container>
  constexpr bool operator<=(const stack<T, Container>& x, const stack<T, Container>& y);
```

5 *Returns*: `x.c <= y.c`.

```
template<class T, class Container>
  constexpr bool operator>=(const stack<T, Container>& x, const stack<T, Container>& y);
```

6 *Returns*: `x.c >= y.c`.

```
template<class T, three_way_comparable Container>
  constexpr compare_three_way_result_t<Container>
    operator<=>(const stack<T, Container>& x, const stack<T, Container>& y);
```

7 *Returns*: `x.c <=> y.c`.

23.6.6.7 Specialized algorithms [stack.special]

```
template<class T, class Container>
  constexpr void swap(stack<T, Container>& x, stack<T, Container>& y)
    noexcept(noexcept(x.swap(y)));
```

1 *Constraints*: `is_swappable_v<Container>` is `true`.

2 *Effects*: As if by `x.swap(y)`.

23.6.7 Header `<flat_map>` synopsis [flat.map.syn]

```
#include <compare>             // see 17.12.1
#include <initializer_list>    // see 17.11.2
```

```
namespace std {
  // 23.6.8, class template flat_map
  template<class Key, class T, class Compare = less<Key>,
           class KeyContainer = vector<Key>, class MappedContainer = vector<T>>

      erase_if(flat_multimap<Key, T, Compare, KeyContainer, MappedContainer>& c, Predicate pred);
}
```

23.6.8 Class template `flat_map` [flat.map]

23.6.8.1 Overview [flat.map.overview]

1 A `flat_map` is a container adaptor that provides an associative container interface that supports unique keys (i.e., contains at most one of each key value) and provides for fast retrieval of values of another type `T` based on the keys. `flat_map` supports iterators that meet the *Cpp17InputIterator* requirements and model the `random_access_iterator` concept (24.3.4.13).

2 A `flat_map` meets all of the requirements of a container (23.2.2.2) and of a reversible container (23.2.2.3), plus the optional container requirements (23.2.2.4). `flat_map` meets the requirements of an associative container (23.2.7), except that:

(2.1) — it does not meet the requirements related to node handles (23.2.5),

(2.2) — it does not meet the requirements related to iterator invalidation, and

(2.3) — the time complexity of the operations that insert or erase a single element from the map is linear, including the ones that take an insertion position iterator.

[*Note 1*: A `flat_map` does not meet the additional requirements of an allocator-aware container (23.2.2.5). — *end note*]

3 A `flat_map` also provides most operations described in 23.2.7 for unique keys. This means that a `flat_map` supports the `a_uniq` operations in 23.2.7 but not the `a_eq` operations. For a `flat_map<Key, T>` the `key_type` is `Key` and the `value_type` is `pair<Key, T>`.

4 Descriptions are provided here only for operations on `flat_map` that are not described in one of those sets of requirements or for operations where there is additional semantic information.

5 A `flat_map` maintains the following invariants:

(5.1) — it contains the same number of keys and values;

(5.2) — the keys are sorted with respect to the comparison object; and

(5.3) — the value at offset `off` within the value container is the value associated with the key at offset `off` within the key container.

6 If any member function in 23.6.8.2 exits via an exception the invariants of the object argument are restored. For the move constructor and move assignment operator, the invariants of both arguments are restored.

[*Note 2*: This can result in the `flat_map` being emptied. — *end note*]

7 Any type `C` that meets the sequence container requirements (23.2.4) can be used to instantiate `flat_map`, as long as `C::iterator` meets the *Cpp17RandomAccessIterator* requirements and invocations of member functions `C::size` and `C::max_size` do not exit via an exception. In particular, `vector` (23.3.13) and `deque` (23.3.5) can be used.

[*Note 3*: `vector<bool>` is not a sequence container. — *end note*]

8 The program is ill-formed if `Key` is not the same type as `KeyContainer::value_type` or `T` is not the same type as `MappedContainer::value_type`.

9 The effect of calling a constructor that takes both `key_container_type` and `mapped_container_type` arguments with containers of different sizes is undefined.

10 The effect of calling a member function that takes a `sorted_unique_t` argument with a container, containers, or range that is not sorted with respect to `key_comp()`, or that contains equal elements, is undefined.

11 The types `iterator` and `const_iterator` meet the constexpr iterator requirements (24.3.1).

23.6.8.2 Definition [flat.map.defn]

```
namespace std {
  template<class Key, class T, class Compare = less<Key>,
           class KeyContainer = vector<Key>, class MappedContainer = vector<T>>
  class flat_map {
  public:
    // types
    using key_type               = Key;
    using mapped_type            = T;
    using value_type             = pair<key_type, mapped_type>;
    using key_compare            = Compare;
    using reference              = pair<const key_type&, mapped_type&>;
    using const_reference        = pair<const key_type&, const mapped_type&>;
    using size_type              = size_t;
    using difference_type        = ptrdiff_t;
    using iterator               = implementation-defined; // see 23.2
    using const_iterator         = implementation-defined; // see 23.2
    using reverse_iterator       = std::reverse_iterator<iterator>;
    using const_reverse_iterator = std::reverse_iterator<const_iterator>;
    using key_container_type     = KeyContainer;
    using mapped_container_type  = MappedContainer;

    class value_compare {
    private:
      key_compare comp;                                          // exposition only
      constexpr value_compare(key_compare c) : comp(c) { }       // exposition only

    public:

```

```
}
```

1 The member type `containers` has the data members and special members specified above. It has no base classes or members other than those specified.

23.6.8.3 Constructors [flat.map.cons]

```
constexpr flat_map(key_container_type key_cont, mapped_container_type mapped_cont,
                   const key_compare& comp = key_compare());
```

1 *Effects*: Initializes `c.keys` with `std::move(key_cont)`, `c.values` with `std::move(mapped_cont)`, and *`compare`* with `comp`; sorts the range [`begin()`, `end()`) with respect to `value_comp()`; and finally erases the duplicate elements as if by:

```
auto zv = views::zip(c.keys, c.values);
auto it = ranges::unique(zv, key-equiv(compare)).begin();
auto dist = distance(zv.begin(), it);
c.keys.erase(c.keys.begin() + dist, c.keys.end());
c.values.erase(c.values.begin() + dist, c.values.end());
```

2 *Complexity*: Linear in N if the container arguments are already sorted with respect to `value_comp()` and otherwise $N \log N$, where N is the value of `key_cont.size()` before this call.

```
constexpr flat_map(sorted_unique_t, key_container_type key_cont, mapped_container_type mapped_cont,
                   const key_compare& comp = key_compare());
```

3 *Effects*: Initializes `c.keys` with `std::move(key_cont)`, `c.values` with `std::move(mapped_cont)`, and *`compare`* with `comp`.

4 *Complexity*: Constant.

23.6.8.4 Constructors with allocators [flat.map.cons.alloc]

1 The constructors in this subclause shall not participate in overload resolution unless `uses_allocator_v<key_container_type, Alloc>` is `true` and `uses_allocator_v<mapped_container_type, Alloc>` is `true`.

```
template<class Alloc>
  constexpr flat_map(const key_container_type& key_cont, const mapped_container_type& mapped_cont,
                     const Alloc& a);
template<class Alloc>
  constexpr flat_map(const key_container_type& key_cont, const mapped_container_type& mapped_cont,
                     const key_compare& comp, const Alloc& a);
```

2 *Effects*: Equivalent to `flat_map(key_cont, mapped_cont)` and `flat_map(key_cont, mapped_cont, comp)`, respectively, except that `c.keys` and `c.values` are constructed with uses-allocator construction (20.2.8.2).

3 *Complexity*: Same as `flat_map(key_cont, mapped_cont)` and `flat_map(key_cont, mapped_cont, comp)`, respectively.

```
template<class Alloc>
  constexpr flat_map(sorted_unique_t, const key_container_type& key_cont,
                     const mapped_container_type& mapped_cont, const Alloc& a);
template<class Alloc>
  constexpr flat_map(sorted_unique_t, const key_container_type& key_cont,
                     const mapped_container_type& mapped_cont, const key_compare& comp,
                     const Alloc& a);
```

4 *Effects*: Equivalent to `flat_map(sorted_unique, key_cont, mapped_cont)` and `flat_map(sorted_unique, key_cont, mapped_cont, comp)`, respectively, except that `c.keys` and `c.values` are constructed with uses-allocator construction (20.2.8.2).

5 *Complexity*: Linear.

```
template<class Alloc>
  constexpr explicit flat_map(const Alloc& a);
template<class Alloc>
  constexpr flat_map(const key_compare& comp, const Alloc& a);
template<class Alloc>
  constexpr flat_map(const flat_map&, const Alloc& a);
```

```
template<class Alloc>
  constexpr flat_map(flat_map&&, const Alloc& a);
template<class InputIterator, class Alloc>
  constexpr flat_map(InputIterator first, InputIterator last, const Alloc& a);
template<class InputIterator, class Alloc>
  constexpr flat_map(InputIterator first, InputIterator last, const key_compare& comp,
                     const Alloc& a);
template<class InputIterator, class Alloc>
  constexpr flat_map(sorted_unique_t, InputIterator first, InputIterator last, const Alloc& a);
template<class InputIterator, class Alloc>
  constexpr flat_map(sorted_unique_t, InputIterator first, InputIterator last,
                     const key_compare& comp, const Alloc& a);
template<container-compatible-range<value_type> R, class Alloc>
  constexpr flat_map(from_range_t, R&& rg, const Alloc& a);
template<container-compatible-range<value_type> R, class Alloc>
  constexpr flat_map(from_range_t, R&& rg, const key_compare& comp, const Alloc& a);
template<class Alloc>
  constexpr flat_map(initializer_list<value_type> il, const Alloc& a);
template<class Alloc>
  constexpr flat_map(initializer_list<value_type> il, const key_compare& comp, const Alloc& a);
template<class Alloc>
  constexpr flat_map(sorted_unique_t, initializer_list<value_type> il, const Alloc& a);
template<class Alloc>
  constexpr flat_map(sorted_unique_t, initializer_list<value_type> il,
                     const key_compare& comp, const Alloc& a);
```

6 *Effects*: Equivalent to the corresponding non-allocator constructors except that `c.keys` and `c.values` are constructed with uses-allocator construction (20.2.8.2).

23.6.8.5 Capacity [flat.map.capacity]

```
constexpr size_type size() const noexcept;
```

1 *Returns*: `c.keys.size()`.

```
constexpr size_type max_size() const noexcept;
```

2 *Returns*: `min<size_type>(c.keys.max_size(), c.values.max_size())`.

23.6.8.6 Access [flat.map.access]

```
constexpr mapped_type& operator[](const key_type& x);
```

1 *Effects*: Equivalent to: `return try_emplace(x).first->second;`

```
constexpr mapped_type& operator[](key_type&& x);
```

2 *Effects*: Equivalent to: `return try_emplace(std::move(x)).first->second;`

```
template<class K> constexpr mapped_type& operator[](K&& x);
```

3 *Constraints*: The *qualified-id* `Compare::is_transparent` is valid and denotes a type.

4 *Effects*: Equivalent to: `return try_emplace(std::forward<K>(x)).first->second;`

```
constexpr mapped_type&       at(const key_type& x);
constexpr const mapped_type& at(const key_type& x) const;
```

5 *Returns*: A reference to the `mapped_type` corresponding to `x` in `*this`.

6 *Throws*: An exception object of type `out_of_range` if no such element is present.

7 *Complexity*: Logarithmic.

```
template<class K> constexpr mapped_type&       at(const K& x);
template<class K> constexpr const mapped_type& at(const K& x) const;
```

8 *Constraints*: The *qualified-id* `Compare::is_transparent` is valid and denotes a type.

9 *Preconditions*: The expression `find(x)` is well-formed and has well-defined behavior.

10 *Returns*: A reference to the `mapped_type` corresponding to `x` in `*this`.

11 *Throws*: An exception object of type `out_of_range` if no such element is present.

12 *Complexity*: Logarithmic.

23.6.8.7 Modifiers [flat.map.modifiers]

```
template<class... Args> constexpr pair<iterator, bool> emplace(Args&&... args);
```

1 *Constraints*: `is_constructible_v<pair<key_type, mapped_type>, Args...>` is `true`.

2 *Effects*: Initializes an object `t` of type `pair<key_type, mapped_type>` with `std::forward<Args>(args)...`; if the map already contains an element whose key is equivalent to `t.first`, `*this` is unchanged. Otherwise, equivalent to:

```
auto key_it = ranges::upper_bound(c.keys, t.first, compare);
auto value_it = c.values.begin() + distance(c.keys.begin(), key_it);
c.keys.insert(key_it, std::move(t.first));
c.values.insert(value_it, std::move(t.second));
```

3 *Returns*: The `bool` component of the returned pair is `true` if and only if the insertion took place, and the iterator component of the pair points to the element with key equivalent to `t.first`.

```
template<class P> constexpr pair<iterator, bool> insert(P&& x);
template<class P> constexpr iterator insert(const_iterator position, P&& x);
```

4 *Constraints*: `is_constructible_v<pair<key_type, mapped_type>, P>` is `true`.

5 *Effects*: The first form is equivalent to `return emplace(std::forward<P>(x));`. The second form is equivalent to `return emplace_hint(position, std::forward<P>(x));`.

```
template<class InputIterator>
  constexpr void insert(InputIterator first, InputIterator last);
```

6 *Effects*: Adds elements to `c` as if by:

```
for (; first != last; ++first) {
  value_type value = *first;
  c.keys.insert(c.keys.end(), std::move(value.first));
  c.values.insert(c.values.end(), std::move(value.second));
}
```

Then, sorts the range of newly inserted elements with respect to `value_comp()`; merges the resulting sorted range and the sorted range of pre-existing elements into a single sorted range; and finally erases the duplicate elements as if by:

```
auto zv = views::zip(c.keys, c.values);
auto it = ranges::unique(zv, key-equiv(compare)).begin();
auto dist = distance(zv.begin(), it);
c.keys.erase(c.keys.begin() + dist, c.keys.end());
c.values.erase(c.values.begin() + dist, c.values.end());
```

7 *Complexity*: $N + M \log M$, where N is `size()` before the operation and M is `distance(first, last)`.

8 *Remarks*: Since this operation performs an in-place merge, it may allocate memory.

```
template<class InputIterator>
  constexpr void insert(sorted_unique_t, InputIterator first, InputIterator last);
```

9 *Effects*: Equivalent to `insert(first, last)`.

10 *Complexity*: Linear in N, where N is `size()` after the operation.

```
template<container-compatible-range<value_type> R>
  constexpr void insert_range(R&& rg);
```

11 *Effects*: Adds elements to `c` as if by:

```
ranges::for_each(rg, [&](value_type e) {
  c.keys.insert(c.keys.end(), std::move(e.first));
  c.values.insert(c.values.end(), std::move(e.second));
});
```

Then, sorts the range of newly inserted elements with respect to `value_comp()`; merges the resulting sorted range and the sorted range of pre-existing elements into a single sorted range; and finally erases the duplicate elements as if by:

```
auto zv = views::zip(c.keys, c.values);
auto it = ranges::unique(zv, key-equiv(compare)).begin();
auto dist = distance(zv.begin(), it);
c.keys.erase(c.keys.begin() + dist, c.keys.end());
c.values.erase(c.values.begin() + dist, c.values.end());
```

12 *Complexity*: $N + M \log M$, where N is `size()` before the operation and M is `ranges::distance(rg)`.

13 *Remarks*: Since this operation performs an in-place merge, it may allocate memory.

```
template<container-compatible-range<value_type> R>
  constexpr void insert_range(sorted_unique_t, R&& rg);
```

14 *Effects*: Equivalent to `insert_range(rg)`.

15 *Complexity*: Linear in N, where N is `size()` after the operation.

```
template<class... Args>
  constexpr pair<iterator, bool> try_emplace(const key_type& k, Args&&... args);
template<class... Args>
  constexpr pair<iterator, bool> try_emplace(key_type&& k, Args&&... args);
template<class... Args>
  constexpr iterator try_emplace(const_iterator hint, const key_type& k, Args&&... args);
template<class... Args>
  constexpr iterator try_emplace(const_iterator hint, key_type&& k, Args&&... args);
```

16 *Constraints*: `is_constructible_v<mapped_type, Args...>` is `true`.

17 *Effects*: If the map already contains an element whose key is equivalent to `k`, `*this` and `args...` are unchanged. Otherwise equivalent to:

```
auto key_it = ranges::upper_bound(c.keys, k, compare);
auto value_it = c.values.begin() + distance(c.keys.begin(), key_it);
c.keys.insert(key_it, std::forward<decltype(k)>(k));
c.values.emplace(value_it, std::forward<Args>(args)...);
```

18 *Returns*: In the first two overloads, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

19 *Complexity*: The same as `emplace` for the first two overloads, and the same as `emplace_hint` for the last two overloads.

```
template<class K, class... Args>
  constexpr pair<iterator, bool> try_emplace(K&& k, Args&&... args);
template<class K, class... Args>
  constexpr iterator try_emplace(const_iterator hint, K&& k, Args&&... args);
```

20 *Constraints*:

(20.1) — The *qualified-id* `Compare::is_transparent` is valid and denotes a type.

(20.2) — `is_constructible_v<key_type, K>` is `true`.

(20.3) — `is_constructible_v<mapped_type, Args...>` is `true`.

(20.4) — For the first overload, `is_convertible_v<K&&, const_iterator>` and `is_convertible_v<K&&, iterator>` are both `false`.

21 *Preconditions*: The conversion from `k` into `key_type` constructs an object `u`, for which `find(k) == find(u)` is `true`.

22 *Effects*: If the map already contains an element whose key is equivalent to `k`, `*this` and `args...` are unchanged. Otherwise equivalent to:

```
auto key_it = upper_bound(c.keys.begin(), c.keys.end(), k, compare);
auto value_it = c.values.begin() + distance(c.keys.begin(), key_it);
c.keys.emplace(key_it, std::forward<K>(k));
c.values.emplace(value_it, std::forward<Args>(args)...);
```

23 *Returns*: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

24 *Complexity*: The same as `emplace` and `emplace_hint`, respectively.

```
template<class M>
  constexpr pair<iterator, bool> insert_or_assign(const key_type& k, M&& obj);
template<class M>
  constexpr pair<iterator, bool> insert_or_assign(key_type&& k, M&& obj);
template<class M>
  constexpr iterator insert_or_assign(const_iterator hint, const key_type& k, M&& obj);
template<class M>
  constexpr iterator insert_or_assign(const_iterator hint, key_type&& k, M&& obj);
```

25 *Constraints*: `is_assignable_v<mapped_type&, M>` is `true` and `is_constructible_v<mapped_type, M>` is `true`.

26 *Effects*: If the map already contains an element `e` whose key is equivalent to `k`, assigns `std::forward<M>(obj)` to `e.second`. Otherwise, equivalent to

```
try_emplace(std::forward<decltype(k)>(k), std::forward<M>(obj))
```

for the first two overloads or

```
try_emplace(hint, std::forward<decltype(k)>(k), std::forward<M>(obj))
```

for the last two overloads.

27 *Returns*: In the first two overloads, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

28 *Complexity*: The same as `emplace` for the first two overloads and the same as `emplace_hint` for the last two overloads.

```
template<class K, class M>
  constexpr pair<iterator, bool> insert_or_assign(K&& k, M&& obj);
template<class K, class M>
  constexpr iterator insert_or_assign(const_iterator hint, K&& k, M&& obj);
```

29 *Constraints*:

(29.1) — The *qualified-id* `Compare::is_transparent` is valid and denotes a type.

(29.2) — `is_constructible_v<key_type, K>` is `true`.

(29.3) — `is_assignable_v<mapped_type&, M>` is `true`.

(29.4) — `is_constructible_v<mapped_type, M>` is `true`.

30 *Preconditions*: The conversion from `k` into `key_type` constructs an object `u`, for which `find(k) == find(u)` is `true`.

31 *Effects*: If the map already contains an element `e` whose key is equivalent to `k`, assigns `std::forward<M>(obj)` to `e.second`. Otherwise, equivalent to

```
try_emplace(std::forward<K>(k), std::forward<M>(obj))
```

for the first overload or

```
try_emplace(hint, std::forward<K>(k), std::forward<M>(obj))
```

for the second overload.

32 *Returns*: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

33 *Complexity*: The same as `emplace` and `emplace_hint`, respectively.

```
constexpr void swap(flat_map& y)
  noexcept(is_nothrow_swappable_v<key_container_type> &&
           is_nothrow_swappable_v<mapped_container_type> &&
           is_nothrow_swappable_v<key_compare>);
```

34 *Effects*: Equivalent to:

```
ranges::swap(compare, y.compare);
ranges::swap(c.keys, y.c.keys);
```

```
    ranges::swap(c.values, y.c.values);
constexpr containers extract() &&;
```

35 *Postconditions*: `*this` is emptied, even if the function exits via an exception.

36 *Returns*: `std::move(c)`.

```
constexpr void replace(key_container_type&& key_cont, mapped_container_type&& mapped_cont);
```

37 *Preconditions*: `key_cont.size() == mapped_cont.size()` is `true`, the elements of `key_cont` are sorted with respect to *`compare`*, and `key_cont` contains no equal elements.

38 *Effects*: Equivalent to:

```
c.keys = std::move(key_cont);
c.values = std::move(mapped_cont);
```

23.6.8.8 Erasure [flat.map.erasure]

```
template<class Key, class T, class Compare, class KeyContainer, class MappedContainer,
         class Predicate>
  constexpr typename flat_map<Key, T, Compare, KeyContainer, MappedContainer>::size_type
    erase_if(flat_map<Key, T, Compare, KeyContainer, MappedContainer>& c, Predicate pred);
```

1 *Preconditions*: `Key` and `T` meet the *Cpp17MoveAssignable* requirements.

2 *Effects*: Let E be `bool(pred(pair<const Key&, const T&>(e)))`. Erases all elements `e` in `c` for which E holds.

3 *Returns*: The number of elements erased.

4 *Complexity*: Exactly `c.size()` applications of the predicate.

5 *Remarks*: Stable (16.4.6.8). If an invocation of `erase_if` exits via an exception, `c` is in a valid but unspecified state (3.68).

[*Note 1*: `c` still meets its invariants, but can be empty. — *end note*]

23.6.9 Class template `flat_multimap` [flat.multimap]

23.6.9.1 Overview [flat.multimap.overview]

1 A `flat_multimap` is a container adaptor that provides an associative container interface that supports equivalent keys (i.e., possibly containing multiple copies of the same key value) and provides for fast retrieval of values of another type `T` based on the keys. `flat_multimap` supports iterators that meet the *Cpp17InputIterator* requirements and model the `random_access_iterator` concept (24.3.4.13).

2 A `flat_multimap` meets all of the requirements for a container (23.2.2.2) and for a reversible container (23.2.2.3), plus the optional container requirements (23.2.2.4). `flat_multimap` meets the requirements of an associative container (23.2.7), except that:

(2.1) — it does not meet the requirements related to node handles (23.2.5),

(2.2) — it does not meet the requirements related to iterator invalidation, and

(2.3) — the time complexity of the operations that insert or erase a single element from the map is linear, including the ones that take an insertion position iterator.

[*Note 1*: A `flat_multimap` does not meet the additional requirements of an allocator-aware container (23.2.2.5). — *end note*]

3 A `flat_multimap` also provides most operations described in 23.2.7 for equal keys. This means that a `flat_multimap` supports the `a_eq` operations in 23.2.7 but not the `a_uniq` operations. For a `flat_multimap<Key, T>` the `key_type` is `Key` and the `value_type` is `pair<Key, T>`.

4 Except as otherwise noted, operations on `flat_multimap` are equivalent to those of `flat_map`, except that `flat_multimap` operations do not remove or replace elements with equal keys.

[*Example 1*: `flat_multimap` constructors and emplace do not erase non-unique elements after sorting them. — *end example*]

5 A `flat_multimap` maintains the following invariants:

(5.1) — it contains the same number of keys and values;

(5.2) — the keys are sorted with respect to the comparison object; and

(5.3) — the value at offset `off` within the value container is the value associated with the key at offset `off` within the key container.

6 If any member function in 23.6.9.2 exits via an exception, the invariants of the object argument are restored. For the move constructor and move assignment operator, the invariants of both arguments are restored.

[*Note 2*: This can result in the `flat_multimap` being emptied. — *end note*]

7 Any type `C` that meets the sequence container requirements (23.2.4) can be used to instantiate `flat_multimap`, as long as `C::iterator` meets the *Cpp17RandomAccessIterator* requirements and invocations of member functions `C::size` and `C::max_size` do not exit via an exception. In particular, `vector` (23.3.13) and `deque` (23.3.5) can be used.

[*Note 3*: `vector<bool>` is not a sequence container. — *end note*]

8 The program is ill-formed if `Key` is not the same type as `KeyContainer::value_type` or `T` is not the same type as `MappedContainer::value_type`.

9 The effect of calling a constructor that takes both `key_container_type` and `mapped_container_type` arguments with containers of different sizes is undefined.

10 The effect of calling a member function that takes a `sorted_equivalent_t` argument with a container, containers, or range that are not sorted with respect to `key_comp()` is undefined.

11 The types `iterator` and `const_iterator` meet the constexpr iterator requirements (24.3.1).

23.6.9.2 Definition [flat.multimap.defn]

```
namespace std {
  template<class Key, class T, class Compare = less<Key>,
           class KeyContainer = vector<Key>, class MappedContainer = vector<T>>

```

1 The member type `containers` has the data members and special members specified above. It has no base classes or members other than those specified.

23.6.9.3 Constructors [flat.multimap.cons]

```
constexpr flat_multimap(key_container_type key_cont, mapped_container_type mapped_cont,
                        const key_compare& comp = key_compare());
```

1 *Effects*: Initializes *c*`.keys` with `std::move(key_cont)`, *c*`.values` with `std::move(mapped_cont)`, and *`compare`* with `comp`; sorts the range [`begin()`, `end()`) with respect to `value_comp()`.

2 *Complexity*: Linear in N if the container arguments are already sorted with respect to `value_comp()` and otherwise $N \log N$, where N is the value of `key_cont.size()` before this call.

```
constexpr flat_multimap(sorted_equivalent_t, key_container_type key_cont,
                        mapped_container_type mapped_cont,
                        const key_compare& comp = key_compare());
```

3 *Effects*: Initializes *c*`.keys` with `std::move(key_cont)`, *c*`.values` with `std::move(mapped_cont)`, and *`compare`* with `comp`.

4 *Complexity*: Constant.

23.6.9.4 Constructors with allocators [flat.multimap.cons.alloc]

1 The constructors in this subclause shall not participate in overload resolution unless `uses_allocator_v<key_container_type, Alloc>` is `true` and `uses_allocator_v<mapped_container_type, Alloc>` is `true`.

```
template<class Alloc>
  constexpr flat_multimap(const key_container_type& key_cont,
                          const mapped_container_type& mapped_cont, const Alloc& a);
template<class Alloc>
  constexpr flat_multimap(const key_container_type& key_cont,
                          const mapped_container_type& mapped_cont,
                          const key_compare& comp, const Alloc& a);
```

2 *Effects*: Equivalent to `flat_multimap(key_cont, mapped_cont)` and `flat_multimap(key_cont, mapped_cont, comp)`, respectively, except that *c*`.keys` and *c*`.values` are constructed with uses-allocator construction (20.2.8.2).

3 *Complexity*: Same as `flat_multimap(key_cont, mapped_cont)` and `flat_multimap(key_cont, mapped_cont, comp)`, respectively.

```
template<class Alloc>
  constexpr flat_multimap(sorted_equivalent_t, const key_container_type& key_cont,
                          const mapped_container_type& mapped_cont, const Alloc& a);
template<class Alloc>
  constexpr flat_multimap(sorted_equivalent_t, const key_container_type& key_cont,
                          const mapped_container_type& mapped_cont, const key_compare& comp,
                          const Alloc& a);
```

4 *Effects*: Equivalent to `flat_multimap(sorted_equivalent, key_cont, mapped_cont)` and `flat_multimap(sorted_equivalent, key_cont, mapped_cont, comp)`, respectively, except that `c.keys` and `c.values` are constructed with uses-allocator construction (20.2.8.2).

5 *Complexity*: Linear.

```
template<class Alloc>
  constexpr explicit flat_multimap(const Alloc& a);
template<class Alloc>
  constexpr flat_multimap(const key_compare& comp, const Alloc& a);
template<class Alloc>
  constexpr flat_multimap(const flat_multimap&, const Alloc& a);
template<class Alloc>
  constexpr flat_multimap(flat_multimap&&, const Alloc& a);
template<class InputIterator, class Alloc>
  constexpr flat_multimap(InputIterator first, InputIterator last, const Alloc& a);
template<class InputIterator, class Alloc>
  constexpr flat_multimap(InputIterator first, InputIterator last, const key_compare& comp,
                          const Alloc& a);
template<class InputIterator, class Alloc>
  constexpr flat_multimap(sorted_equivalent_t, InputIterator first, InputIterator last,
                          const Alloc& a);
template<class InputIterator, class Alloc>
  constexpr flat_multimap(sorted_equivalent_t, InputIterator first, InputIterator last,
                          const key_compare& comp, const Alloc& a);
template<container-compatible-range<value_type> R, class Alloc>
  constexpr flat_multimap(from_range_t, R&& rg, const Alloc& a);
template<container-compatible-range<value_type> R, class Alloc>
  constexpr flat_multimap(from_range_t, R&& rg, const key_compare& comp, const Alloc& a);
template<class Alloc>
  constexpr flat_multimap(initializer_list<value_type> il, const Alloc& a);
template<class Alloc>
  constexpr flat_multimap(initializer_list<value_type> il, const key_compare& comp,
                          const Alloc& a);
template<class Alloc>
  constexpr flat_multimap(sorted_equivalent_t, initializer_list<value_type> il, const Alloc& a);
template<class Alloc>
  constexpr flat_multimap(sorted_equivalent_t, initializer_list<value_type> il,
                          const key_compare& comp, const Alloc& a);
```

6 *Effects*: Equivalent to the corresponding non-allocator constructors except that `c.keys` and `c.values` are constructed with uses-allocator construction (20.2.8.2).

23.6.9.5 Erasure [flat.multimap.erasure]

```
template<class Key, class T, class Compare, class KeyContainer, class MappedContainer,
         class Predicate>
  constexpr typename flat_multimap<Key, T, Compare, KeyContainer, MappedContainer>::size_type
    erase_if(flat_multimap<Key, T, Compare, KeyContainer, MappedContainer>& c, Predicate pred);
```

1 *Preconditions*: `Key` and `T` meet the *Cpp17MoveAssignable* requirements.

2 *Effects*: Let E be `bool(pred(pair<const Key&, const T&>(e)))`. Erases all elements `e` in `c` for which E holds.

3 *Returns*: The number of elements erased.

4 *Complexity*: Exactly `c.size()` applications of the predicate.

5 *Remarks*: Stable (16.4.6.8). If an invocation of `erase_if` exits via an exception, `c` is in a valid but unspecified state (3.68).

[*Note 1*: `c` still meets its invariants, but can be empty. — *end note*]

23.6.10 Header `<flat_set>` synopsis [flat.set.syn]

```
#include <compare>             // see 17.12.1
#include <initializer_list>    // see 17.11.2

namespace std {
  // 23.6.11, class template flat_set
  template<class Key, class Compare = less<Key>, class KeyContainer = vector<Key>>
    class flat_set;

  struct sorted_unique_t { explicit sorted_unique_t() = default; };
  inline constexpr sorted_unique_t sorted_unique{};

  template<class Key, class Compare, class KeyContainer, class Allocator>
    struct uses_allocator<flat_set<Key, Compare, KeyContainer>, Allocator>;

  // 23.6.11.6, erasure for flat_set
  template<class Key, class Compare, class KeyContainer, class Predicate>
    constexpr typename flat_set<Key, Compare, KeyContainer>::size_type
      erase_if(flat_set<Key, Compare, KeyContainer>& c, Predicate pred);

  // 23.6.12, class template flat_multiset
  template<class Key, class Compare = less<Key>, class KeyContainer = vector<Key>>
    class flat_multiset;

  struct sorted_equivalent_t { explicit sorted_equivalent_t() = default; };
  inline constexpr sorted_equivalent_t sorted_equivalent{};

  template<class Key, class Compare, class KeyContainer, class Allocator>
    struct uses_allocator<flat_multiset<Key, Compare, KeyContainer>, Allocator>;

  // 23.6.12.6, erasure for flat_multiset
  template<class Key, class Compare, class KeyContainer, class Predicate>
    constexpr typename flat_multiset<Key, Compare, KeyContainer>::size_type
      erase_if(flat_multiset<Key, Compare, KeyContainer>& c, Predicate pred);
}
```

23.6.11 Class template `flat_set` [flat.set]

23.6.11.1 Overview [flat.set.overview]

1 A `flat_set` is a container adaptor that provides an associative container interface that supports unique keys (i.e., contains at most one of each key value) and provides for fast retrieval of the keys themselves. `flat_set` supports iterators that model the `random_access_iterator` concept (24.3.4.13).

2 A `flat_set` meets all of the requirements for a container (23.2.2.2) and for a reversible container (23.2.2.3), plus the optional container requirements (23.2.2.4). `flat_set` meets the requirements of an associative container (23.2.7), except that:

(2.1) — it does not meet the requirements related to node handles (23.2.5.1),

(2.2) — it does not meet the requirements related to iterator invalidation, and

(2.3) — the time complexity of the operations that insert or erase a single element from the set is linear, including the ones that take an insertion position iterator.

[*Note 1*: A `flat_set` does not meet the additional requirements of an allocator-aware container, as described in 23.2.2.5. — *end note*]

3 A `flat_set` also provides most operations described in 23.2.7 for unique keys. This means that a `flat_set` supports the `a_uniq` operations in 23.2.7 but not the `a_eq` operations. For a `flat_set<Key>`, both the `key_type` and `value_type` are `Key`.

4 Descriptions are provided here only for operations on `flat_set` that are not described in one of those sets of requirements or for operations where there is additional semantic information.

5 A `flat_set` maintains the invariant that the keys are sorted with respect to the comparison object.

6 If any member function in 23.6.11.2 exits via an exception, the invariant of the object argument is restored. For the move constructor and move assignment operator, the invariants of both arguments are restored.

[*Note 2*: This can result in the `flat_set`'s being emptied. — *end note*]

7 Any sequence container (23.2.4) supporting *Cpp17RandomAccessIterator* can be used to instantiate `flat_set`. In particular, `vector` (23.3.13) and `deque` (23.3.5) can be used.

[*Note 3*: `vector<bool>` is not a sequence container. — *end note*]

8 The program is ill-formed if `Key` is not the same type as `KeyContainer::value_type`.

9 The effect of calling a member function that takes a `sorted_unique_t` argument with a range that is not sorted with respect to `key_comp()`, or that contains equal elements, is undefined.

10 The types `iterator` and `const_iterator` meet the constexpr iterator requirements (24.3.1).

23.6.11.2 Definition [flat.set.defn]

```
namespace std {
  template<class Key, class Compare = less<Key>, class KeyContainer = vector<Key>>
  class flat_set {
  public:
    // types
    using key_type               = Key;
    using value_type             = Key;
    using key_compare            = Compare;
    using value_compare          = Compare;
    using reference              = value_type&;
    using const_reference        = const value_type&;
    using size_type              = KeyContainer::size_type;
    using difference_type        = KeyContainer::difference_type;
    using iterator               = implementation-defined;     // see 23.2
    using const_iterator         = implementation-defined;     // see 23.2
    using reverse_iterator       = std::reverse_iterator<iterator>;
    using const_reverse_iterator = std::reverse_iterator<const_iterator>;
    using container_type         = KeyContainer;

    // 23.6.11.3, constructors
    constexpr flat_set() : flat_set(key_compare()) { }

    constexpr flat_set(const flat_set&);
    constexpr flat_set(flat_set&&);
    constexpr flat_set& operator=(const flat_set&);
    constexpr flat_set& operator=(flat_set&&);

    constexpr explicit flat_set(const key_compare& comp)
      : c(), compare(comp) { }

    constexpr explicit flat_set(container_type cont, const key_compare& comp = key_compare());

}
```

23.6.11.3 Constructors [flat.set.cons]

```
constexpr explicit flat_set(container_type cont, const key_compare& comp = key_compare());
```

1 *Effects*: Initializes `c` with `std::move(cont)` and *`compare`* with `comp`, sorts the range [`begin()`, `end()`) with respect to *`compare`*, and finally erases all but the first element from each group of consecutive equivalent elements.

2 *Complexity*: Linear in N if `cont` is already sorted with respect to *`compare`* and otherwise $N \log N$, where N is the value of `cont.size()` before this call.

23.6.11.4 Constructors with allocators [flat.set.cons.alloc]

1 The constructors in this subclause shall not participate in overload resolution unless `uses_allocator_v<container_type, Alloc>` is `true`.

```
template<class Alloc>
  constexpr flat_set(const container_type& cont, const Alloc& a);
template<class Alloc>
  constexpr flat_set(const container_type& cont, const key_compare& comp, const Alloc& a);
```

2 *Effects*: Equivalent to `flat_set(cont)` and `flat_set(cont, comp)`, respectively, except that `c` is constructed with uses-allocator construction (20.2.8.2).

3 *Complexity*: Same as `flat_set(cont)` and `flat_set(cont, comp)`, respectively.

```
template<class Alloc>
  constexpr flat_set(sorted_unique_t, const container_type& cont, const Alloc& a);
```

```
template<class Alloc>
  constexpr flat_set(sorted_unique_t, const container_type& cont,
                     const key_compare& comp, const Alloc& a);
```

4 *Effects*: Equivalent to `flat_set(sorted_unique, cont)` and `flat_set(sorted_unique, cont, comp)`, respectively, except that `c` is constructed with uses-allocator construction (20.2.8.2).

5 *Complexity*: Linear.

```
template<class Alloc>
  constexpr explicit flat_set(const Alloc& a);
template<class Alloc>
  constexpr flat_set(const key_compare& comp, const Alloc& a);
template<class Alloc>
  constexpr flat_set(const flat_set&, const Alloc& a);
template<class Alloc>
  constexpr flat_set(flat_set&&, const Alloc& a);
template<class InputIterator, class Alloc>
  constexpr flat_set(InputIterator first, InputIterator last, const Alloc& a);
template<class InputIterator, class Alloc>
  constexpr flat_set(InputIterator first, InputIterator last, const key_compare& comp,
                     const Alloc& a);
template<class InputIterator, class Alloc>
  constexpr flat_set(sorted_unique_t, InputIterator first, InputIterator last, const Alloc& a);
template<class InputIterator, class Alloc>
  constexpr flat_set(sorted_unique_t, InputIterator first, InputIterator last,
                     const key_compare& comp, const Alloc& a);
template<container-compatible-range<value_type> R, class Alloc>
  constexpr flat_set(from_range_t, R&& rg, const Alloc& a);
template<container-compatible-range<value_type> R, class Alloc>
  constexpr flat_set(from_range_t, R&& rg, const key_compare& comp, const Alloc& a);
template<class Alloc>
  constexpr flat_set(initializer_list<value_type> il, const Alloc& a);
template<class Alloc>
  constexpr flat_set(initializer_list<value_type> il, const key_compare& comp, const Alloc& a);
template<class Alloc>
  constexpr flat_set(sorted_unique_t, initializer_list<value_type> il, const Alloc& a);
template<class Alloc>
  constexpr flat_set(sorted_unique_t, initializer_list<value_type> il,
                     const key_compare& comp, const Alloc& a);
```

6 *Effects*: Equivalent to the corresponding non-allocator constructors except that `c` is constructed with uses-allocator construction (20.2.8.2).

23.6.11.5 Modifiers [flat.set.modifiers]

```
template<class K> constexpr pair<iterator, bool> insert(K&& x);
template<class K> constexpr iterator insert(const_iterator hint, K&& x);
```

1 *Constraints*: The *qualified-id* `Compare::is_transparent` is valid and denotes a type. `is_constructible_v<value_type, K>` is `true`.

2 *Preconditions*: The conversion from `x` into `value_type` constructs an object `u`, for which `find(x) == find(u)` is `true`.

3 *Effects*: If the set already contains an element equivalent to `x`, `*this` and `x` are unchanged. Otherwise, inserts a new element as if by `emplace(std::forward<K>(x))`.

4 *Returns*: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the element whose key is equivalent to `x`.

```
template<class InputIterator>
  constexpr void insert(InputIterator first, InputIterator last);
```

5 *Effects*: Adds elements to `c` as if by:

```
c.insert(c.end(), first, last);
```

Then, sorts the range of newly inserted elements with respect to *compare*; merges the resulting sorted range and the sorted range of pre-existing elements into a single sorted range; and finally erases all but the first element from each group of consecutive equivalent elements.

6 *Complexity*: $N + M \log M$, where N is `size()` before the operation and M is `distance(first, last)`.

7 *Remarks*: Since this operation performs an in-place merge, it may allocate memory.

```
template<class InputIterator>
  constexpr void insert(sorted_unique_t, InputIterator first, InputIterator last);
```

8 *Effects*: Equivalent to `insert(first, last)`.

9 *Complexity*: Linear.

```
template<container-compatible-range<value_type> R>
  constexpr void insert_range(R&& rg);
```

10 *Effects*: Adds elements to `c` as if by:

```
ranges::for_each(rg, [&](value_type e) {
  c.insert(c.end(), std::move(e));
});
```

Then, sorts the range of newly inserted elements with respect to *compare*; merges the resulting sorted range and the sorted range of pre-existing elements into a single sorted range; and finally erases all but the first element from each group of consecutive equivalent elements.

11 *Complexity*: $N + M \log M$, where N is `size()` before the operation and M is `ranges::distance(rg)`.

12 *Remarks*: Since this operation performs an in-place merge, it may allocate memory.

```
template<container-compatible-range<value_type> R>
  constexpr void insert_range(sorted_unique_t, R&& rg);
```

13 *Effects*: Equivalent to `insert_range(rg)`.

14 *Complexity*: Linear in N, where N is `size()` after the operation.

```
constexpr void swap(flat_set& y)
  noexcept(is_nothrow_swappable_v<container_type> &&
           is_nothrow_swappable_v<key_compare>);
```

15 *Effects*: Equivalent to:

```
ranges::swap(compare, y.compare);
ranges::swap(c, y.c);
```

```
constexpr container_type extract() &&;
```

16 *Postconditions*: `*this` is emptied, even if the function exits via an exception.

17 *Returns*: `std::move(c)`.

```
constexpr void replace(container_type&& cont);
```

18 *Preconditions*: The elements of `cont` are sorted with respect to *compare*, and `cont` contains no equal elements.

19 *Effects*: Equivalent to: `c = std::move(cont);`

23.6.11.6 Erasure [flat.set.erasure]

```
template<class Key, class Compare, class KeyContainer, class Predicate>
  constexpr typename flat_set<Key, Compare, KeyContainer>::size_type
    erase_if(flat_set<Key, Compare, KeyContainer>& c, Predicate pred);
```

1 *Preconditions*: `Key` meets the *Cpp17MoveAssignable* requirements.

2 *Effects*: Let E be `bool(pred(as_const(e)))`. Erases all elements `e` in `c` for which E holds.

3 *Returns*: The number of elements erased.

4 *Complexity*: Exactly `c.size()` applications of the predicate.

5 *Remarks*: Stable (16.4.6.8). If an invocation of `erase_if` exits via an exception, `c` is in a valid but unspecified state (3.68).

[*Note 1*: `c` still meets its invariants, but can be empty. — *end note*]

23.6.12 Class template `flat_multiset` [flat.multiset]

23.6.12.1 Overview [flat.multiset.overview]

1 A `flat_multiset` is a container adaptor that provides an associative container interface that supports equivalent keys (i.e., possibly containing multiple copies of the same key value) and provides for fast retrieval of the keys themselves. `flat_multiset` supports iterators that model the `random_access_iterator` concept (24.3.4.13).

2 A `flat_multiset` meets all of the requirements for a container (23.2.2.2) and for a reversible container (23.2.2.3), plus the optional container requirements (23.2.2.4). `flat_multiset` meets the requirements of an associative container (23.2.7), except that:

(2.1) — it does not meet the requirements related to node handles (23.2.5.1),

(2.2) — it does not meet the requirements related to iterator invalidation, and

(2.3) — the time complexity of the operations that insert or erase a single element from the set is linear, including the ones that take an insertion position iterator.

[*Note 1*: A `flat_multiset` does not meet the additional requirements of an allocator-aware container, as described in 23.2.2.5. — *end note*]

3 A `flat_multiset` also provides most operations described in 23.2.7 for equal keys. This means that a `flat_multiset` supports the `a_eq` operations in 23.2.7 but not the `a_uniq` operations. For a `flat_multiset<Key>`, both the `key_type` and `value_type` are `Key`.

4 Descriptions are provided here only for operations on `flat_multiset` that are not described in one of the general sections or for operations where there is additional semantic information.

5 A `flat_multiset` maintains the invariant that the keys are sorted with respect to the comparison object.

6 If any member function in 23.6.12.2 exits via an exception, the invariant of the object argument is restored. For the move constructor and move assignment operator, the invariants of both arguments are restored.

[*Note 2*: This can result in the `flat_multiset`'s being emptied. — *end note*]

7 Any sequence container (23.2.4) supporting *Cpp17RandomAccessIterator* can be used to instantiate `flat_multiset`. In particular, `vector` (23.3.13) and `deque` (23.3.5) can be used.

[*Note 3*: `vector<bool>` is not a sequence container. — *end note*]

8 The program is ill-formed if `Key` is not the same type as `KeyContainer::value_type`.

9 The effect of calling a member function that takes a `sorted_equivalent_t` argument with a range that is not sorted with respect to `key_comp()` is undefined.

10 The types `iterator` and `const_iterator` meet the constexpr iterator requirements (24.3.1).

23.6.12.2 Definition [flat.multiset.defn]

```
namespace std {
  template<class Key, class Compare = less<Key>, class KeyContainer = vector<Key>>
  class flat_multiset {
  public:
    // types
    using key_type               = Key;
    using value_type             = Key;
    using key_compare            = Compare;
    using value_compare          = Compare;
    using reference              = value_type&;
    using const_reference        = const value_type&;
    using size_type              = KeyContainer::size_type;
    using difference_type        = KeyContainer::difference_type;
    using iterator               = implementation-defined;      // see 23.2
    using const_iterator         = implementation-defined;      // see 23.2
    using reverse_iterator       = std::reverse_iterator<iterator>;
    using const_reverse_iterator = std::reverse_iterator<const_iterator>;
```

```
using container_type         = KeyContainer;

    struct uses_allocator<flat_multiset<Key, Compare, KeyContainer>, Allocator>
      : bool_constant<uses_allocator_v<KeyContainer, Allocator>> { };
}
```

23.6.12.3 Constructors [flat.multiset.cons]

```
constexpr explicit flat_multiset(container_type cont, const key_compare& comp = key_compare());
```

1 *Effects*: Initializes `c` with `std::move(cont)` and *`compare`* with `comp`, and sorts the range [`begin()`, `end()`) with respect to *`compare`*.

2 *Complexity*: Linear in N if `cont` is already sorted with respect to *`compare`* and otherwise $N \log N$, where N is the value of `cont.size()` before this call.

23.6.12.4 Constructors with allocators [flat.multiset.cons.alloc]

1 The constructors in this subclause shall not participate in overload resolution unless `uses_allocator_v<container_type, Alloc>` is `true`.

```
template<class Alloc>
  constexpr flat_multiset(const container_type& cont, const Alloc& a);
template<class Alloc>
  constexpr flat_multiset(const container_type& cont, const key_compare& comp, const Alloc& a);
```

2 *Effects*: Equivalent to `flat_multiset(cont)` and `flat_multiset(cont, comp)`, respectively, except that `c` is constructed with uses-allocator construction (20.2.8.2).

3 *Complexity*: Same as `flat_multiset(cont)` and `flat_multiset(cont, comp)`, respectively.

```
template<class Alloc>
  constexpr flat_multiset(sorted_equivalent_t, const container_type& cont, const Alloc& a);
template<class Alloc>
  constexpr flat_multiset(sorted_equivalent_t, const container_type& cont,
                          const key_compare& comp, const Alloc& a);
```

4 *Effects*: Equivalent to `flat_multiset(sorted_equivalent, cont)` and `flat_multiset(sorted_equivalent, cont, comp)`, respectively, except that `c` is constructed with uses-allocator construction (20.2.8.2).

5 *Complexity*: Linear.

```
template<class Alloc>
  constexpr explicit flat_multiset(const Alloc& a);
template<class Alloc>
  constexpr flat_multiset(const key_compare& comp, const Alloc& a);
template<class Alloc>
  constexpr flat_multiset(const flat_multiset&, const Alloc& a);
template<class Alloc>
  constexpr flat_multiset(flat_multiset&&, const Alloc& a);
template<class InputIterator, class Alloc>
  constexpr flat_multiset(InputIterator first, InputIterator last, const Alloc& a);
template<class InputIterator, class Alloc>
  constexpr flat_multiset(InputIterator first, InputIterator last,
                          const key_compare& comp, const Alloc& a);
template<class InputIterator, class Alloc>
  constexpr flat_multiset(sorted_equivalent_t, InputIterator first, InputIterator last,
                          const Alloc& a);
template<class InputIterator, class Alloc>
  constexpr flat_multiset(sorted_equivalent_t, InputIterator first, InputIterator last,
                          const key_compare& comp, const Alloc& a);
template<container-compatible-range<value_type> R, class Alloc>
  constexpr flat_multiset(from_range_t, R&& rg, const Alloc& a);
template<container-compatible-range<value_type> R, class Alloc>
  constexpr flat_multiset(from_range_t, R&& rg, const key_compare& comp, const Alloc& a);
template<class Alloc>
  constexpr flat_multiset(initializer_list<value_type> il, const Alloc& a);
```

```
template<class Alloc>
  constexpr flat_multiset(initializer_list<value_type> il, const key_compare& comp,
                          const Alloc& a);
template<class Alloc>
  constexpr flat_multiset(sorted_equivalent_t, initializer_list<value_type> il, const Alloc& a);
template<class Alloc>
  constexpr flat_multiset(sorted_equivalent_t, initializer_list<value_type> il,
                          const key_compare& comp, const Alloc& a);
```

6 *Effects*: Equivalent to the corresponding non-allocator constructors except that `c` is constructed with uses-allocator construction (20.2.8.2).

23.6.12.5 Modifiers [flat.multiset.modifiers]

```
template<class... Args> constexpr iterator emplace(Args&&... args);
```

1 *Constraints*: `is_constructible_v<value_type, Args...>` is `true`.

2 *Effects*: First, initializes an object `t` of type `value_type` with `std::forward<Args>(args)...`, then inserts `t` as if by:

```
auto it = ranges::upper_bound(c, t, compare);
c.insert(it, std::move(t));
```

3 *Returns*: An iterator that points to the inserted element.

```
template<class InputIterator>
  constexpr void insert(InputIterator first, InputIterator last);
```

4 *Effects*: Adds elements to `c` as if by:

```
c.insert(c.end(), first, last);
```

Then, sorts the range of newly inserted elements with respect to *`compare`*, and merges the resulting sorted range and the sorted range of pre-existing elements into a single sorted range.

5 *Complexity*: $N + M \log M$, where N is `size()` before the operation and M is `distance(first, last)`.

6 *Remarks*: Since this operation performs an in-place merge, it may allocate memory.

```
template<class InputIterator>
  constexpr void insert(sorted_equivalent_t, InputIterator first, InputIterator last);
```

7 *Effects*: Equivalent to `insert(first, last)`.

8 *Complexity*: Linear in N, where N is `size()` after the operation.

```
template<container-compatible-range<value_type> R>
  constexpr void insert_range(R&& rg);
```

9 *Effects*: Adds elements to `c` as if by:

```
ranges::for_each(rg, [&](value_type e) {
  c.insert(c.end(), std::move(e));
});
```

Then, sorts the range of newly inserted elements with respect to *`compare`*, and merges the resulting sorted range and the sorted range of pre-existing elements into a single sorted range.

10 *Complexity*: $N + M \log M$, where N is `size()` before the operation and M is `ranges::distance(rg)`.

11 *Remarks*: Since this operation performs an in-place merge, it may allocate memory.

```
template<container-compatible-range<value_type> R>
  constexpr void insert_range(sorted_equivalent_t, R&& rg);
```

12 *Effects*: Equivalent to `insert_range(rg)`.

13 *Complexity*: Linear in N, where N is `size()` after the operation.

```
constexpr void swap(flat_multiset& y)
  noexcept(is_nothrow_swappable_v<container_type> &&
           is_nothrow_swappable_v<key_compare>);
```

14 *Effects*: Equivalent to:

```
    ranges::swap(compare, y.compare);
    ranges::swap(c, y.c);
```

```
constexpr container_type extract() &&;
```

15 *Postconditions*: `*this` is emptied, even if the function exits via an exception.

16 *Returns*: `std::move(c)`.

```
constexpr void replace(container_type&& cont);
```

17 *Preconditions*: The elements of `cont` are sorted with respect to *`compare`*.

18 *Effects*: Equivalent to: `c = std::move(cont);`

23.6.12.6 Erasure [flat.multiset.erasure]

```
template<class Key, class Compare, class KeyContainer, class Predicate>
  constexpr typename flat_multiset<Key, Compare, KeyContainer>::size_type
    erase_if(flat_multiset<Key, Compare, KeyContainer>& c, Predicate pred);
```

1 *Preconditions*: `Key` meets the *Cpp17MoveAssignable* requirements.

2 *Effects*: Let E be `bool(pred(as_const(e)))`. Erases all elements `e` in `c` for which E holds.

3 *Returns*: The number of elements erased.

4 *Complexity*: Exactly `c.size()` applications of the predicate.

5 *Remarks*: Stable (16.4.6.8). If an invocation of `erase_if` exits via an exception, `c` is in a valid but unspecified state (3.68).

[*Note 1*: `c` still meets its invariants, but can be empty. — *end note*]

23.6.13 Container adaptors formatting [container.adaptors.format]

1 For each of `queue`, `priority_queue`, and `stack`, the library provides the following constexpr-enabled formatter specialization where *`adaptor-type`* is the name of the template:

```
namespace std {
  template<class charT, class T, formattable<charT> Container, class... U>
  struct formatter<adaptor-type<T, Container, U...>, charT> {
  private:
    using maybe-const-container =                                   // exposition only
      fmt-maybe-const<Container, charT>;
    using maybe-const-adaptor =                                     // exposition only
      maybe-const<is_const_v<maybe-const-container>,                // see 25.2
                  adaptor-type<T, Container, U...>>;
    formatter<ranges::ref_view<maybe-const-container>, charT> underlying_;    // exposition only

  public:
    template<class ParseContext>
      constexpr typename ParseContext::iterator
        parse(ParseContext& ctx);

    template<class FormatContext>
      constexpr typename FormatContext::iterator
        format(maybe-const-adaptor& r, FormatContext& ctx) const;
  };
}
```

```
template<class ParseContext>
  constexpr typename ParseContext::iterator
    parse(ParseContext& ctx);
```

2 *Effects*: Equivalent to: `return underlying_.parse(ctx);`

```
template<class FormatContext>
  constexpr typename FormatContext::iterator
    format(maybe-const-adaptor& r, FormatContext& ctx) const;
```

3 *Effects*: Equivalent to: `return underlying_.format(r.c, ctx);`

23.7 Views [views]

23.7.1 General [views.general]

1 The header `<span>` (23.7.2.1) defines the view `span`. The header `<mdspan>` (23.7.3.2) defines the class template `mdspan` and other facilities for interacting with these multidimensional views.

2 In addition to being available via inclusion of the `<span>` (23.7.2.1) header, `dynamic_extent` is available when the header `<mdspan>` (23.7.3.2) is included.

23.7.2 Contiguous access [views.contiguous]

23.7.2.1 Header `<span>` synopsis [span.syn]

```
// mostly freestanding
namespace std {
  // constants
  inline constexpr size_t dynamic_extent = numeric_limits<size_t>::max();

  template<class T>
    concept integral-constant-like =                    // exposition only
      is_integral_v<remove_cvref_t<decltype(T::value)>> &&
      !is_same_v<bool, remove_cvref_t<decltype(T::value)>> &&
      constexpr-wrapper-like<T>;

  template<class T>
    constexpr size_t maybe-static-ext = dynamic_extent; // exposition only
  template<integral-constant-like T>
    constexpr size_t maybe-static-ext<T> = {T::value};

  // 23.7.2.2, class template span
  template<class ElementType, size_t Extent = dynamic_extent>
    class span;                                         // partially freestanding

  template<class ElementType, size_t Extent>
    constexpr bool ranges::enable_view<span<ElementType, Extent>> = true;
  template<class ElementType, size_t Extent>
    constexpr bool ranges::enable_borrowed_range<span<ElementType, Extent>> = true;

  // 23.7.2.3, views of object representation
  template<class ElementType, size_t Extent>
    span<const byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
      as_bytes(span<ElementType, Extent> s) noexcept;

  template<class ElementType, size_t Extent>
    span<byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
      as_writable_bytes(span<ElementType, Extent> s) noexcept;
}
```

23.7.2.2 Class template span [views.span]

23.7.2.2.1 Overview [span.overview]

1 A `span` is a view over a contiguous sequence of objects, the storage of which is owned by some other object.

2 All member functions of `span` have constant time complexity.

```
namespace std {
  template<class ElementType, size_t Extent = dynamic_extent>
  class span {
  public:
    // constants and types
    using element_type = ElementType;
    using value_type = remove_cv_t<ElementType>;
    using size_type = size_t;
    using difference_type = ptrdiff_t;
    using pointer = element_type*;
    using const_pointer = const element_type*;
    using reference = element_type&;
```

```
  using const_reference = const element_type&;
  using iterator = implementation-defined;        // see 23.7.2.2.7
  using const_iterator = std::const_iterator<iterator>;
  using reverse_iterator = std::reverse_iterator<iterator>;
  using const_reverse_iterator = std::const_iterator<reverse_iterator>;
  static constexpr size_type extent = Extent;

  // 23.7.2.2.2, constructors, copy, and assignment
  constexpr span() noexcept;
  template<class It>
    constexpr explicit(extent != dynamic_extent) span(It first, size_type count);
  template<class It, class End>
    constexpr explicit(extent != dynamic_extent) span(It first, End last);
  template<size_t N>
    constexpr span(type_identity_t<element_type> (&arr)[N]) noexcept;
  template<class T, size_t N>
    constexpr span(array<T, N>& arr) noexcept;
  template<class T, size_t N>
    constexpr span(const array<T, N>& arr) noexcept;
  template<class R>
    constexpr explicit(extent != dynamic_extent) span(R&& r);
  constexpr span(const span& other) noexcept = default;
  template<class OtherElementType, size_t OtherExtent>
    constexpr explicit(see below) span(const span<OtherElementType, OtherExtent>& s) noexcept;

  constexpr span& operator=(const span& other) noexcept = default;

  // 23.7.2.2.4, subviews
  template<size_t Count>
    constexpr span<element_type, Count> first() const;
  template<size_t Count>
    constexpr span<element_type, Count> last() const;
  template<size_t Offset, size_t Count = dynamic_extent>
    constexpr span<element_type, see below> subspan() const;

  constexpr span<element_type, dynamic_extent> first(size_type count) const;
  constexpr span<element_type, dynamic_extent> last(size_type count) const;
  constexpr span<element_type, dynamic_extent> subspan(
    size_type offset, size_type count = dynamic_extent) const;

  // 23.7.2.2.5, observers
  constexpr size_type size() const noexcept;
  constexpr size_type size_bytes() const noexcept;
  constexpr bool empty() const noexcept;

  // 23.7.2.2.6, element access
  constexpr reference operator[](size_type idx) const;
  constexpr reference at(size_type idx) const;                    // freestanding-deleted
  constexpr reference front() const;
  constexpr reference back() const;
  constexpr pointer data() const noexcept;

  // 23.7.2.2.7, iterator support
  constexpr iterator begin() const noexcept;
  constexpr iterator end() const noexcept;
  constexpr const_iterator cbegin() const noexcept { return begin(); }
  constexpr const_iterator cend() const noexcept { return end(); }
  constexpr reverse_iterator rbegin() const noexcept;
  constexpr reverse_iterator rend() const noexcept;
  constexpr const_reverse_iterator crbegin() const noexcept { return rbegin(); }
  constexpr const_reverse_iterator crend() const noexcept { return rend(); }

private:
  pointer data_;              // exposition only
```

```
    size_type size_;              // exposition only
  };

  template<class It, class EndOrSize>
    span(It, EndOrSize) -> span<remove_reference_t<iter_reference_t<It>>,
                                maybe-static-ext<EndOrSize>>;
  template<class T, size_t N>
    span(T (&)[N]) -> span<T, N>;
  template<class T, size_t N>
    span(array<T, N>&) -> span<T, N>;
  template<class T, size_t N>
    span(const array<T, N>&) -> span<const T, N>;
  template<class R>
    span(R&&) -> span<remove_reference_t<ranges::range_reference_t<R>>>;
}
```

3 `span<ElementType, Extent>` is a trivially copyable type (6.9.1).

4 `ElementType` is required to be a complete object type that is not an abstract class type.

5 For a `span s`, any operation that invalidates a pointer in the range [`s.data()`, `s.data() + s.size()`) invalidates pointers, iterators, and references to elements of `s`.

23.7.2.2.2 Constructors, copy, and assignment [span.cons]

```
constexpr span() noexcept;
```

1 *Constraints*: `Extent == dynamic_extent || Extent == 0` is `true`.

2 *Postconditions*: `size() == 0 && data() == nullptr`.

```
template<class It>
  constexpr explicit(extent != dynamic_extent) span(It first, size_type count);
```

3 *Constraints*: Let `U` be `remove_reference_t<iter_reference_t<It>>`.

(3.1) — `It` satisfies `contiguous_iterator`.

(3.2) — `is_convertible_v<U(*)[], element_type(*)[]>` is `true`.

[*Note 1*: The intent is to allow only qualification conversions of the iterator reference type to `element_type`. — *end note*]

4 *Preconditions*:

(4.1) — [`first`, `first + count`) is a valid range.

(4.2) — `It` models `contiguous_iterator`.

5 *Hardened preconditions*: If `extent` is not equal to `dynamic_extent`, then `count == extent` is `true`.

6 *Effects*: Initializes *`data_`* with `to_address(first)` and *`size_`* with `count`.

7 *Throws*: Nothing.

```
template<class It, class End>
  constexpr explicit(extent != dynamic_extent) span(It first, End last);
```

8 *Constraints*: Let `U` be `remove_reference_t<iter_reference_t<It>>`.

(8.1) — `is_convertible_v<U(*)[], element_type(*)[]>` is `true`.

[*Note 2*: The intent is to allow only qualification conversions of the iterator reference type to `element_type`. — *end note*]

(8.2) — `It` satisfies `contiguous_iterator`.

(8.3) — `End` satisfies `sized_sentinel_for<It>`.

(8.4) — `is_convertible_v<End, size_t>` is `false`.

9 *Preconditions*:

(9.1) — [`first`, `last`) is a valid range.

(9.2) — `It` models `contiguous_iterator`.

(9.3) — `End` models `sized_sentinel_for<It>`.

10 *Hardened preconditions*: If `extent` is not equal to `dynamic_extent`, then `(last - first) == extent` is `true`.

11 *Effects*: Initializes *`data_`* with `to_address(first)` and *`size_`* with `last - first`.

12 *Throws*: When and what `last - first` throws.

```
template<size_t N> constexpr span(type_identity_t<element_type> (&arr)[N]) noexcept;
template<class T, size_t N> constexpr span(array<T, N>& arr) noexcept;
template<class T, size_t N> constexpr span(const array<T, N>& arr) noexcept;
```

13 *Constraints*: Let `U` be `remove_pointer_t<decltype(std::data(arr))>`.

(13.1) — `extent == dynamic_extent || N == extent` is `true`, and

(13.2) — `is_convertible_v<U(*)[], element_type(*)[]>` is `true`.

[*Note 3*: The intent is to allow only qualification conversions of the array element type to `element_type`. — *end note*]

14 *Effects*: Constructs a `span` that is a view over the supplied array.

[*Note 4*: `type_identity_t` affects class template argument deduction. — *end note*]

15 *Postconditions*: `size() == N && data() == std::data(arr)` is `true`.

```
template<class R> constexpr explicit(extent != dynamic_extent) span(R&& r);
```

16 *Constraints*: Let `U` be `remove_reference_t<ranges::range_reference_t<R>>`.

(16.1) — `R` satisfies `ranges::contiguous_range` and `ranges::sized_range`.

(16.2) — Either `R` satisfies `ranges::borrowed_range` or `is_const_v<element_type>` is `true`.

(16.3) — `remove_cvref_t<R>` is not a specialization of `span`.

(16.4) — `remove_cvref_t<R>` is not a specialization of `array`.

(16.5) — `is_array_v<remove_cvref_t<R>>` is `false`.

(16.6) — `is_convertible_v<U(*)[], element_type(*)[]>` is `true`.

[*Note 5*: The intent is to allow only qualification conversions of the range reference type to `element_type`. — *end note*]

17 *Preconditions*:

(17.1) — `R` models `ranges::contiguous_range` and `ranges::sized_range`.

(17.2) — If `is_const_v<element_type>` is `false`, `R` models `ranges::borrowed_range`.

18 *Hardened preconditions*: If `extent` is not equal to `dynamic_extent`, then `ranges::size(r) == extent` is `true`.

19 *Effects*: Initializes *`data_`* with `ranges::data(r)` and *`size_`* with `ranges::size(r)`.

20 *Throws*: What and when `ranges::data(r)` and `ranges::size(r)` throw.

```
constexpr span(const span& other) noexcept = default;
```

21 *Postconditions*: `other.size() == size() && other.data() == data()`.

```
template<class OtherElementType, size_t OtherExtent>
  constexpr explicit(see below) span(const span<OtherElementType, OtherExtent>& s) noexcept;
```

22 *Constraints*:

(22.1) — `extent == dynamic_extent || OtherExtent == dynamic_extent || extent == OtherExtent` is `true`, and

(22.2) — `is_convertible_v<OtherElementType(*)[], element_type(*)[]>` is `true`.

[*Note 6*: The intent is to allow only qualification conversions of the `OtherElementType` to `element_type`. — *end note*]

23 *Hardened preconditions*: If `extent` is not equal to `dynamic_extent`, then `s.size() == extent` is `true`.

24 *Effects*: Constructs a `span` that is a view over the range [`s.data()`, `s.data() + s.size()`).

25 *Postconditions*: `size() == s.size() && data() == s.data()`.

26 *Remarks*: The expression inside `explicit` is equivalent to:

```
extent != dynamic_extent && OtherExtent == dynamic_extent
```

```
constexpr span& operator=(const span& other) noexcept = default;
```

27 *Postconditions*: `size() == other.size() && data() == other.data()`.

23.7.2.2.3 Deduction guides [span.deduct]

```
template<class It, class EndOrSize>
  span(It, EndOrSize) -> span<remove_reference_t<iter_reference_t<It>>,
                              maybe-static-ext<EndOrSize>>;
```

1 *Constraints*: `It` satisfies `contiguous_iterator`.

```
template<class R>
  span(R&&) -> span<remove_reference_t<ranges::range_reference_t<R>>>;
```

2 *Constraints*: `R` satisfies `ranges::contiguous_range`.

23.7.2.2.4 Subviews [span.sub]

```
template<size_t Count> constexpr span<element_type, Count> first() const;
```

1 *Mandates*: `Count <= Extent` is `true`.

2 *Hardened preconditions*: `Count <= size()` is `true`.

3 *Effects*: Equivalent to: `return R(data(), Count);` where `R` is the return type.

```
template<size_t Count> constexpr span<element_type, Count> last() const;
```

4 *Mandates*: `Count <= Extent` is `true`.

5 *Hardened preconditions*: `Count <= size()` is `true`.

6 *Effects*: Equivalent to: `return R(data() + (size() - Count), Count);` where `R` is the return type.

```
template<size_t Offset, size_t Count = dynamic_extent>
  constexpr span<element_type, see below> subspan() const;
```

7 *Mandates*:

```
Offset <= Extent && (Count == dynamic_extent || Count <= Extent - Offset)
```

is `true`.

8 *Hardened preconditions*:

```
Offset <= size() && (Count == dynamic_extent || Count <= size() - Offset)
```

is `true`.

9 *Effects*: Equivalent to:

```
return span<ElementType, see below>(
  data() + Offset, Count != dynamic_extent ? Count : size() - Offset);
```

10 *Remarks*: The second template argument of the returned `span` type is:

```
Count != dynamic_extent ? Count
                        : (Extent != dynamic_extent ? Extent - Offset
                                                    : dynamic_extent)
```

```
constexpr span<element_type, dynamic_extent> first(size_type count) const;
```

11 *Hardened preconditions*: `count <= size()` is `true`.

12 *Effects*: Equivalent to: `return R(data(), count);` where `R` is the return type.

```
constexpr span<element_type, dynamic_extent> last(size_type count) const;
```

13 *Hardened preconditions*: `count <= size()` is `true`.

14 *Effects*: Equivalent to: `return R(data() + (size() - count), count);` where `R` is the return type.

```
constexpr span<element_type, dynamic_extent> subspan(
  size_type offset, size_type count = dynamic_extent) const;
```

15 *Hardened preconditions*:

```
offset <= size() && (count == dynamic_extent || count <= size() - offset)
```

is `true`.

16 *Effects*: Equivalent to:

```
return R(data() + offset, count == dynamic_extent ? size() - offset : count);
```

where `R` is the return type.

23.7.2.2.5 Observers [span.obs]

```
constexpr size_type size() const noexcept;
```

1 *Effects*: Equivalent to: `return` *`size_`*`;`

```
constexpr size_type size_bytes() const noexcept;
```

2 *Effects*: Equivalent to: `return size() * sizeof(element_type);`

```
constexpr bool empty() const noexcept;
```

3 *Effects*: Equivalent to: `return size() == 0;`

23.7.2.2.6 Element access [span.elem]

```
constexpr reference operator[](size_type idx) const;
```

1 *Hardened preconditions*: `idx < size()` is `true`.

2 *Returns*: `*(data() + idx)`.

3 *Throws*: Nothing.

```
constexpr reference at(size_type idx) const;
```

4 *Returns*: `*(data() + idx)`.

5 *Throws*: `out_of_range` if `idx >= size()` is `true`.

```
constexpr reference front() const;
```

6 *Hardened preconditions*: `empty()` is `false`.

7 *Returns*: `*data()`.

8 *Throws*: Nothing.

```
constexpr reference back() const;
```

9 *Hardened preconditions*: `empty()` is `false`.

10 *Returns*: `*(data() + (size() - 1))`.

11 *Throws*: Nothing.

```
constexpr pointer data() const noexcept;
```

12 *Returns*: *`data_`*.

23.7.2.2.7 Iterator support [span.iterators]

```
using iterator = implementation-defined;
```

1 The type models `contiguous_iterator` (24.3.4.14), meets the *Cpp17RandomAccessIterator* requirements (24.3.5.7), and meets the requirements for constexpr iterators (24.3.1), whose value type is `value_type` and whose reference type is `reference`.

2 All requirements on container iterators (23.2.2.2) apply to `span::iterator` as well.

```
constexpr iterator begin() const noexcept;
```

3 *Returns*: An iterator referring to the first element in the span. If `empty()` is `true`, then it returns the same value as `end()`.

```
constexpr iterator end() const noexcept;
```

4 *Returns*: An iterator which is the past-the-end value.

```
constexpr reverse_iterator rbegin() const noexcept;
```

5 *Effects*: Equivalent to: `return reverse_iterator(end());`

```
constexpr reverse_iterator rend() const noexcept;
```

6 *Effects*: Equivalent to: `return reverse_iterator(begin());`

23.7.2.3 Views of object representation [span.objectrep]

```
template<class ElementType, size_t Extent>
  span<const byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
    as_bytes(span<ElementType, Extent> s) noexcept;
```

1 *Constraints*: `is_volatile_v<ElementType>` is `false`.

2 *Effects*: Equivalent to: `return R{reinterpret_cast<const byte*>(s.data()), s.size_bytes()};` where `R` is the return type.

```
template<class ElementType, size_t Extent>
  span<byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
    as_writable_bytes(span<ElementType, Extent> s) noexcept;
```

3 *Constraints*: `is_const_v<ElementType>` is `false` and `is_volatile_v<ElementType>` is `false`.

4 *Effects*: Equivalent to: `return R{reinterpret_cast<byte*>(s.data()), s.size_bytes()};` where `R` is the return type.

23.7.3 Multidimensional access [views.multidim]

23.7.3.1 Overview [mdspan.overview]

1 A *multidimensional index space* is a Cartesian product of integer intervals. Each interval can be represented by a half-open range $[L_i, U_i)$, where L_i and U_i are the lower and upper bounds of the i^{th} dimension. The *rank* of a multidimensional index space is the number of intervals it represents. The *size of a multidimensional index space* is the product of $U_i - L_i$ for each dimension i if its rank is greater than 0, and 1 otherwise.

2 An integer r is a *rank index* of an index space S if r is in the range $[0, \text{rank of } S)$.

3 A pack of integers `idx` is a *multidimensional index* in a multidimensional index space S (or representation thereof) if both of the following are true:

(3.1) — `sizeof...(idx)` is equal to the rank of S, and

(3.2) — for every rank index i of S, the i^{th} value of `idx` is an integer in the interval $[L_i, U_i)$ of S.

23.7.3.2 Header `<mdspan>` synopsis [mdspan.syn]

```
// mostly freestanding
namespace std {
  // 23.7.3.3, class template extents
  template<class IndexType, size_t... Extents>
    class extents;

  // 23.7.3.3.6, alias template dextents
  template<class IndexType, size_t Rank>
    using dextents = see below;

  // 23.7.3.3.7, alias template dims
  template<size_t Rank, class IndexType = size_t>
    using dims = see below;

  // 23.7.3.4, layout mapping
  struct layout_left;
  struct layout_right;
  struct layout_stride;
  template<size_t PaddingValue = dynamic_extent>
    struct layout_left_padded;
```

```
  template<size_t PaddingValue = dynamic_extent>
    struct layout_right_padded;

  // 23.7.3.5.3, class template default_accessor
  template<class ElementType>
    class default_accessor;

  // 23.7.3.5.4, class template aligned_accessor
  template<class ElementType, size_t ByteAlignment>
    class aligned_accessor;

  // 23.7.3.6, class template mdspan
  template<class ElementType, class Extents, class LayoutPolicy = layout_right,
           class AccessorPolicy = default_accessor<ElementType>>
    class mdspan;                                                    // partially freestanding

  // 23.7.3.7, submdspan creation
  template<class OffsetType, class LengthType, class StrideType>

      convertible_to<tuple_element_t<1, T>, IndexType>;
}
```

23.7.3.3 Class template extents [mdspan.extents]

23.7.3.3.1 Overview [mdspan.extents.overview]

The class template `extents` represents a multidimensional index space of rank equal to `sizeof...(Extents)`. In 23.7, `extents` is used synonymously with multidimensional index space.

```
namespace std {
  template<class IndexType, size_t... Extents>
  class extents {
  public:
    using index_type = IndexType;
    using size_type = make_unsigned_t<index_type>;
    using rank_type = size_t;
```

```
    // 23.7.3.3.4, observers of the multidimensional index space
    static constexpr rank_type rank() noexcept { return sizeof...(Extents); }
    static constexpr rank_type rank_dynamic() noexcept { return dynamic-index(rank()); }
    static constexpr size_t static_extent(rank_type) noexcept;
    constexpr index_type extent(rank_type) const noexcept;

    // 23.7.3.3.3, constructors
    constexpr extents() noexcept = default;

    template<class OtherIndexType, size_t... OtherExtents>
      constexpr explicit(see below)
        extents(const extents<OtherIndexType, OtherExtents...>&) noexcept;
    template<class... OtherIndexTypes>
      constexpr explicit extents(OtherIndexTypes...) noexcept;
    template<class OtherIndexType, size_t N>
      constexpr explicit(N != rank_dynamic())
        extents(span<OtherIndexType, N>) noexcept;
    template<class OtherIndexType, size_t N>
      constexpr explicit(N != rank_dynamic())
        extents(const array<OtherIndexType, N>&) noexcept;

    // 23.7.3.3.5, comparison operators
    template<class OtherIndexType, size_t... OtherExtents>
      friend constexpr bool operator==(const extents&,
                                       const extents<OtherIndexType, OtherExtents...>&) noexcept;

    // 23.7.3.3.2, exposition-only helpers
    constexpr size_t fwd-prod-of-extents(rank_type) const noexcept;     // exposition only
    constexpr size_t rev-prod-of-extents(rank_type) const noexcept;     // exposition only
    template<class OtherIndexType>
      static constexpr auto index-cast(OtherIndexType&&) noexcept;      // exposition only

  private:
    static constexpr rank_type dynamic-index(rank_type) noexcept;       // exposition only
    static constexpr rank_type dynamic-index-inv(rank_type) noexcept;   // exposition only
    array<index_type, rank_dynamic()> dynamic-extents{};                // exposition only
  };

  template<class... Integrals>
    explicit extents(Integrals...)
      -> see below;
}
```

1 *Mandates*:

(1.1) — `IndexType` is a signed or unsigned integer type, and

(1.2) — each element of `Extents` is either equal to `dynamic_extent`, or is representable as a value of type `IndexType`.

2 Each specialization of `extents` models `regular` and is trivially copyable.

3 Let E_r be the r^{th} element of `Extents`. E_r is a *dynamic extent* if it is equal to `dynamic_extent`, otherwise E_r is a *static extent*. Let D_r be the value of *`dynamic-extents`*`[`*`dynamic-index`*`(`r`)]` if E_r is a dynamic extent, otherwise E_r.

4 The r^{th} interval of the multidimensional index space represented by an `extents` object is $[0, D_r)$.

23.7.3.3.2 Exposition-only helpers [mdspan.extents.expo]

```
static constexpr rank_type dynamic-index(rank_type i) noexcept;
```

1 *Preconditions*: `i <= rank()` is `true`.

2 *Returns*: The number of E_r with $r <$ `i` for which E_r is a dynamic extent.

```
static constexpr rank_type dynamic-index-inv(rank_type i) noexcept;
```

3 *Preconditions*: `i < rank_dynamic()` is `true`.

4 *Returns*: The minimum value of r such that `dynamic-index(r + 1) == i + 1` is `true`.

```
constexpr size_t fwd-prod-of-extents(rank_type i) const noexcept;
```

5 *Preconditions*: `i <= rank()` is `true`.

6 *Returns*: If `i > 0` is `true`, the product of `extent(`k`)` for all k in the range $[0, \texttt{i})$, otherwise `1`.

```
constexpr size_t rev-prod-of-extents(rank_type i) const noexcept;
```

7 *Preconditions*: `i < rank()` is `true`.

8 *Returns*: If `i + 1 < rank()` is `true`, the product of `extent(`k`)` for all k in the range $[\texttt{i + 1}, \texttt{rank()})$, otherwise `1`.

```
template<class OtherIndexType>
  static constexpr auto index-cast(OtherIndexType&& i) noexcept;
```

9 *Effects*:

(9.1) — If `remove_cvref_t<OtherIndexType>` is an integral type other than `bool`, then equivalent to `return i;`,

(9.2) — otherwise, equivalent to `return static_cast<index_type>(std::forward<OtherIndexType>(i));`.

[*Note 1*: This function will always return an integral type other than `bool`. Since this function's call sites are constrained on convertibility of `OtherIndexType` to `index_type`, integer-class types can use the `static_cast` branch without loss of precision. — *end note*]

23.7.3.3.3 Constructors [mdspan.extents.cons]

```
template<class OtherIndexType, size_t... OtherExtents>
  constexpr explicit(see below)
    extents(const extents<OtherIndexType, OtherExtents...>& other) noexcept;
```

1 *Constraints*:

(1.1) — `sizeof...(OtherExtents) == rank()` is `true`.

(1.2) — `((OtherExtents == dynamic_extent || Extents == dynamic_extent || OtherExtents == Extents) && ...)` is `true`.

2 *Preconditions*:

(2.1) — `other.extent(`r`)` equals E_r for each r for which E_r is a static extent, and

(2.2) — either

(2.2.1) — `sizeof...(OtherExtents)` is zero, or

(2.2.2) — `other.extent(`r`)` is representable as a value of type `index_type` for every rank index r of `other`.

3 *Postconditions*: `*this == other` is `true`.

4 *Remarks*: The expression inside `explicit` is equivalent to:

```
(((Extents != dynamic_extent) && (OtherExtents == dynamic_extent)) || ... ) ||
(numeric_limits<index_type>::max() < numeric_limits<OtherIndexType>::max())
```

```
template<class... OtherIndexTypes>
  constexpr explicit extents(OtherIndexTypes... exts) noexcept;
```

5 Let `N` be `sizeof...(OtherIndexTypes)`, and let `exts_arr` be `array<index_type, N>{static_cast<index_type>(std::move(exts))...}`.

6 *Constraints*:

(6.1) — `(is_convertible_v<OtherIndexTypes, index_type> && ...)` is `true`,

(6.2) — `(is_nothrow_constructible_v<index_type, OtherIndexTypes> && ...)` is `true`, and

(6.3) — `N == rank_dynamic() || N == rank()` is `true`.

[*Note 1*: One can construct `extents` from just dynamic extents, which are all the values getting stored, or from all the extents with a precondition. — *end note*]

7 *Preconditions*:

(7.1) — If `N != rank_dynamic()` is `true`, `exts_arr[`r`]` equals E_r for each r for which E_r is a static extent, and

(7.2) — either

(7.2.1) — `sizeof...(exts) == 0` is `true`, or

(7.2.2) — each element of `exts` is representable as a nonnegative value of type `index_type`.

8 *Postconditions*: `*this == extents(exts_arr)` is `true`.

```
template<class OtherIndexType, size_t N>
  constexpr explicit(N != rank_dynamic())
    extents(span<OtherIndexType, N> exts) noexcept;
template<class OtherIndexType, size_t N>
  constexpr explicit(N != rank_dynamic())
    extents(const array<OtherIndexType, N>& exts) noexcept;
```

9 *Constraints*:

(9.1) — `is_convertible_v<const OtherIndexType&, index_type>` is `true`,

(9.2) — `is_nothrow_constructible_v<index_type, const OtherIndexType&>` is `true`, and

(9.3) — `N == rank_dynamic() || N == rank()` is `true`.

10 *Preconditions*:

(10.1) — If `N != rank_dynamic()` is `true`, `exts[`r`]` equals E_r for each r for which E_r is a static extent, and

(10.2) — either

(10.2.1) — `N` is zero, or

(10.2.2) — `exts[`r`]` is representable as a nonnegative value of type `index_type` for every rank index r.

11 *Effects*:

(11.1) — If `N` equals `rank_dynamic()`, for all d in the range $[0,$ `rank_dynamic()`$)$, direct-non-list-initializes *`dynamic-extents`*`[`d`]` with `as_const(exts[`d`])`.

(11.2) — Otherwise, for all d in the range $[0,$ `rank_dynamic()`$)$, direct-non-list-initializes *`dynamic-extents`*`[`d`]` with `as_const(exts[`*`dynamic-index-inv`*`(`d`)])`.

```
template<class... Integrals>
  explicit extents(Integrals...) -> see below;
```

12 *Constraints*: `(is_convertible_v<Integrals, size_t> && ...)` is `true`.

13 *Remarks*: The deduced type is `extents<size_t, `*`maybe-static-ext`*`<Integrals>...>`.

23.7.3.3.4 Observers of the multidimensional index space [mdspan.extents.obs]

```
static constexpr size_t static_extent(rank_type i) noexcept;
```

1 *Preconditions*: `i < rank()` is `true`.

2 *Returns*: $E_{\texttt{i}}$.

```
constexpr index_type extent(rank_type i) const noexcept;
```

3 *Preconditions*: `i < rank()` is `true`.

4 *Returns*: $D_{\texttt{i}}$.

23.7.3.3.5 Comparison operators [mdspan.extents.cmp]

```
template<class OtherIndexType, size_t... OtherExtents>
  friend constexpr bool operator==(const extents& lhs,
                                   const extents<OtherIndexType, OtherExtents...>& rhs) noexcept;
```

1 *Returns*: `true` if `lhs.rank()` equals `rhs.rank()` and if `lhs.extent(r)` equals `rhs.extent(r)` for every rank index `r` of `rhs`, otherwise `false`.

23.7.3.3.6 Alias template `dextents` [mdspan.extents.dextents]

```
template<class IndexType, size_t Rank>
  using dextents = see below;
```

1 *Result*: A type `E` that is a specialization of `extents` such that `E::rank() == Rank && E::rank() == E::rank_dynamic()` is `true`, and `E::index_type` denotes `IndexType`.

23.7.3.3.7 Alias template `dims` [mdspan.extents.dims]

```
template<size_t Rank, class IndexType = size_t>
  using dims = see below;
```

1 *Result*: A type `E` that is a specialization of `extents` such that `E::rank() == Rank && E::rank() == E::rank_dynamic()` is `true`, and `E::index_type` denotes `IndexType`.

23.7.3.4 Layout mapping [mdspan.layout]

23.7.3.4.1 General [mdspan.layout.general]

1 In 23.7.3.4.2 and 23.7.3.4.3:

(1.1) — `M` denotes a layout mapping class.

(1.2) — `m` denotes a (possibly const) value of type `M`.

(1.3) — `i` and `j` are packs of (possibly const) integers that are multidimensional indices in `m.extents()` (23.7.3.1).

[*Note 1*: The type of each element of the packs can be a different integer type. — *end note*]

(1.4) — `r` is a (possibly const) rank index of `typename M::extents_type`.

(1.5) — $\texttt{d}_r$ is a pack of (possibly const) integers for which `sizeof...(`$\texttt{d}_r$`) == M::extents_type::rank()` is `true`, the r^{th} element is equal to 1, and all other elements are equal to 0.

2 In 23.7.3.4.2 through 23.7.3.4.7:

(2.1) — Let *`is-mapping-of`* be the exposition-only variable template defined as follows:

```
template<class Layout, class Mapping>
constexpr bool is-mapping-of =  // exposition only
  is_same_v<typename Layout::template mapping<typename Mapping::extents_type>, Mapping>;
```

(2.2) — Let *`is-layout-left-padded-mapping-of`* be the exposition-only variable template defined as follows:

```
template<class Mapping>
constexpr bool is-layout-left-padded-mapping-of = see below;   // exposition only
```

where *`is-layout-left-padded-mapping-of`*`<Mapping>` is `true` if and only if `Mapping` denotes a specialization of `layout_left_padded<S>::mapping` for some value `S` of type `size_t`.

(2.3) — Let *`is-layout-right-padded-mapping-of`* be the exposition-only variable template defined as follows:

```
template<class Mapping>
constexpr bool is-layout-right-padded-mapping-of = see below;   // exposition only
```

where *`is-layout-right-padded-mapping-of`*`<Mapping>` is `true` if and only if `Mapping` denotes a specialization of `layout_right_padded<S>::mapping` for some value `S` of type `size_t`.

(2.4) — For nonnegative integers x and y, let *`LEAST-MULTIPLE-AT-LEAST`*(x, y) denote

(2.4.1) — y if x is zero,

(2.4.2) — otherwise, the least multiple of x that is greater than or equal to y.

23.7.3.4.2 Requirements [mdspan.layout.reqmts]

1 A type `M` meets the *layout mapping* requirements if

(1.1) — `M` models `copyable` and `equality_comparable`,

(1.2) — `is_nothrow_move_constructible_v<M>` is `true`,

(1.3) — `is_nothrow_move_assignable_v<M>` is `true`,

(1.4) — `is_nothrow_swappable_v<M>` is `true`, and

(1.5) — the following types and expressions are well-formed and have the specified semantics.

`typename M::extents_type`

2 *Result*: A type that is a specialization of `extents`.

`typename M::index_type`

3 *Result*: `typename M::extents_type::index_type`.

`typename M::rank_type`

4 *Result*: `typename M::extents_type::rank_type`.

`typename M::layout_type`

5 *Result*: A type `MP` that meets the layout mapping policy requirements (23.7.3.4.3) and for which *`is-mapping-of`*`<MP, M>` is `true`.

`m.extents()`

6 *Result*: `const typename M::extents_type&`

`m(i...)`

7 *Result*: `typename M::index_type`

8 *Returns*: A nonnegative integer less than `numeric_limits<typename M::index_type>::max()` and less than or equal to `numeric_limits<size_t>::max()`.

`m(i...) == m(static_cast<typename M::index_type>(i)...)`

9 *Result*: `bool`

10 *Returns*: `true`

`m.required_span_size()`

11 *Result*: `typename M::index_type`

12 *Returns*: If the size of the multidimensional index space `m.extents()` is 0, then `0`, else `1` plus the maximum value of `m(i...)` for all `i`.

`m.is_unique()`

13 *Result*: `bool`

14 *Returns*: `true` only if for every `i` and `j` where `(i != j || ...)` is `true`, `m(i...) != m(j...)` is `true`.

[*Note 1*: A mapping can return `false` even if the condition is met. For certain layouts, it is possibly not feasible to determine efficiently whether the layout is unique. — *end note*]

`m.is_exhaustive()`

15 *Result*: `bool`

16 *Returns*: `true` only if for all k in the range $[0, $`m.required_span_size()`$)$ there exists an `i` such that `m(i...)` equals k.

[*Note 2*: A mapping can return `false` even if the condition is met. For certain layouts, it is possibly not feasible to determine efficiently whether the layout is exhaustive. — *end note*]

`m.is_strided()`

17 *Result*: `bool`

18 *Returns*: `true` only if for every rank index r of `m.extents()` there exists an integer s_r such that, for all `i` where $(\texttt{i} + d_r)$ is a multidimensional index in `m.extents()` (23.7.3.1), `m((i + `d_r`)...) - m(i...)` equals s_r.

[*Note 3*: This implies that for a strided layout $m(i_0, \ldots, i_k) = m(0, \ldots, 0) + i_0 \times s_0 + \cdots + i_k \times s_k$. — *end note*]

[*Note 4*: A mapping can return `false` even if the condition is met. For certain layouts, it is possibly not feasible to determine efficiently whether the layout is strided. — *end note*]

`m.stride(r)`

19 *Preconditions*: `m.is_strided()` is `true`.

20 *Result*: `typename M::index_type`

21 *Returns*: s_r as defined in `m.is_strided()` above.

22 [*Note 5*: It is not required for `m.stride(r)` to be well-formed if `m.extents().rank()` is zero, even if `m.is_always_strided()` is `true`. — *end note*]

`M::is_always_unique()`

23 *Result*: A constant expression (7.7.3) of type `bool`.

24 *Returns*: `true` only if `m.is_unique()` is `true` for all possible objects `m` of type `M`.

[*Note 6*: A mapping can return `false` even if the above condition is met. For certain layout mappings, it is possibly not feasible to determine whether every instance is unique. — *end note*]

`M::is_always_exhaustive()`

25 *Result*: A constant expression (7.7.3) of type `bool`.

26 *Returns*: `true` only if `m.is_exhaustive()` is `true` for all possible objects `m` of type `M`.

[*Note 7*: A mapping can return `false` even if the above condition is met. For certain layout mappings, it is possibly not feasible to determine whether every instance is exhaustive. — *end note*]

`M::is_always_strided()`

27 *Result*: A constant expression (7.7.3) of type `bool`.

28 *Returns*: `true` only if `m.is_strided()` is `true` for all possible objects `m` of type `M`.

[*Note 8*: A mapping can return `false` even if the above condition is met. For certain layout mappings, it is possibly not feasible to determine whether every instance is strided. — *end note*]

23.7.3.4.3 Layout mapping policy requirements [mdspan.layout.policy.reqmts]

1 A type `MP` meets the *layout mapping policy* requirements if for a type `E` that is a specialization of `extents`, `MP::mapping<E>` is valid and denotes a type `X` that meets the layout mapping requirements (23.7.3.4.2), and for which the *qualified-id* `X::layout_type` is valid and denotes the type `MP` and the *qualified-id* `X::extents_type` denotes `E`.

23.7.3.4.4 Layout mapping policies [mdspan.layout.policy.overview]

```
namespace std {
  struct layout_left {
    template<class Extents>
      class mapping;
  };
  struct layout_right {
    template<class Extents>
      class mapping;
  };
  struct layout_stride {
    template<class Extents>
      class mapping;
  };

  template<size_t PaddingValue>
  struct layout_left_padded {
    template<class Extents> class mapping;
  };
  template<size_t PaddingValue>
  struct layout_right_padded {
    template<class Extents> class mapping;
  };
}
```

1 Each of `layout_left`, `layout_right`, and `layout_stride`, as well as each specialization of `layout_left_padded` and `layout_right_padded`, meets the layout mapping policy requirements and is a trivially copyable type. Furthermore, `is_trivially_default_constructible_v<T>` is `true` for any such type `T`.

23.7.3.4.5 Class template `layout_left::mapping` [mdspan.layout.left]

23.7.3.4.5.1 Overview [mdspan.layout.left.overview]

1 `layout_left` provides a layout mapping where the leftmost extent has stride 1, and strides increase left-to-right as the product of extents.

```
namespace std {
  template<class Extents>
  class layout_left::mapping {
  public:
    using extents_type = Extents;
    using index_type = extents_type::index_type;
    using size_type = extents_type::size_type;
    using rank_type = extents_type::rank_type;
    using layout_type = layout_left;

    // 23.7.3.4.5.2, constructors
    constexpr mapping() noexcept = default;
    constexpr mapping(const mapping&) noexcept = default;
    constexpr mapping(const extents_type&) noexcept;
    template<class OtherExtents>
      constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
        mapping(const mapping<OtherExtents>&) noexcept;
    template<class OtherExtents>
      constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
        mapping(const layout_right::mapping<OtherExtents>&) noexcept;
    template<class LayoutLeftPaddedMapping>
      constexpr explicit(!is_convertible_v<typename LayoutLeftPaddedMapping::extents_type,
                                           extents_type>)
        mapping(const LayoutLeftPaddedMapping&) noexcept;
    template<class OtherExtents>
      constexpr explicit(see below)
        mapping(const layout_stride::mapping<OtherExtents>&);

    constexpr mapping& operator=(const mapping&) noexcept = default;

    // 23.7.3.4.5.3, observers
    constexpr const extents_type& extents() const noexcept { return extents_; }

    constexpr index_type required_span_size() const noexcept;

    template<class... Indices>
      constexpr index_type operator()(Indices...) const noexcept;

    static constexpr bool is_always_unique() noexcept { return true; }
    static constexpr bool is_always_exhaustive() noexcept { return true; }
    static constexpr bool is_always_strided() noexcept { return true; }

    static constexpr bool is_unique() noexcept { return true; }
    static constexpr bool is_exhaustive() noexcept { return true; }
    static constexpr bool is_strided() noexcept { return true; }

    constexpr index_type stride(rank_type) const noexcept;

    template<class OtherExtents>
      friend constexpr bool operator==(const mapping&, const mapping<OtherExtents>&) noexcept;

  private:
    extents_type extents_{};                                    // exposition only

    // 23.7.3.7.7, submdspan mapping specialization
    template<class... SliceSpecifiers>
      constexpr auto submdspan-mapping-impl(SliceSpecifiers...) const     // exposition only
        -> see below;
```

```
    template<class... SliceSpecifiers>
      friend constexpr auto submdspan_mapping(
        const mapping& src, SliceSpecifiers... slices) {
          return src.submdspan-mapping-impl(slices...);
      }
  };
}
```

2 If `Extents` is not a specialization of `extents`, then the program is ill-formed.

3 `layout_left::mapping<E>` is a trivially copyable type that models `regular` for each `E`.

4 *Mandates*: If `Extents::rank_dynamic() == 0` is `true`, then the size of the multidimensional index space `Extents()` is representable as a value of type `typename Extents::index_type`.

23.7.3.4.5.2 Constructors [mdspan.layout.left.cons]

```
constexpr mapping(const extents_type& e) noexcept;
```

1 *Preconditions*: The size of the multidimensional index space `e` is representable as a value of type `index_type` (6.9.2).

2 *Effects*: Direct-non-list-initializes *`extents_`* with `e`.

```
template<class OtherExtents>
  constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
    mapping(const mapping<OtherExtents>& other) noexcept;
```

3 *Constraints*: `is_constructible_v<extents_type, OtherExtents>` is `true`.

4 *Preconditions*: `other.required_span_size()` is representable as a value of type `index_type` (6.9.2).

5 *Effects*: Direct-non-list-initializes *`extents_`* with `other.extents()`.

```
template<class OtherExtents>
  constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
    mapping(const layout_right::mapping<OtherExtents>& other) noexcept;
```

6 *Constraints*:

(6.1) — `extents_type::rank() <= 1` is `true`, and

(6.2) — `is_constructible_v<extents_type, OtherExtents>` is `true`.

7 *Preconditions*: `other.required_span_size()` is representable as a value of type `index_type` (6.9.2).

8 *Effects*: Direct-non-list-initializes *`extents_`* with `other.extents()`.

```
template<class LayoutLeftPaddedMapping>
  constexpr explicit(!is_convertible_v<typename LayoutLeftPaddedMapping::extents_type,
                                       extents_type>)
    mapping(const LayoutLeftPaddedMapping&) noexcept;
```

9 *Constraints*:

(9.1) — *`is-layout-left-padded-mapping-of`*`<LayoutLeftPaddedMapping>` is `true`.

(9.2) — `is_constructible_v<extents_type, typename LayoutLeftPaddedMapping::extents_type>` is `true`.

10 *Mandates*: If

(10.1) — `Extents::rank()` is greater than one,

(10.2) — `Extents::static_extent(0)` does not equal `dynamic_extent`, and

(10.3) — `LayoutLeftPaddedMapping::`*`static-padding-stride`* does not equal `dynamic_extent`,

then `Extents::static_extent(0)` equals `LayoutLeftPaddedMapping::`*`static-padding-stride`*.

11 *Preconditions*:

(11.1) — If `extents_type::rank() > 1` is `true`, then `other.stride(1)` equals `other.extents().extent(0)`.

(11.2) — `other.required_span_size()` is representable as a value of type `index_type`.

12 *Effects*: Direct-non-list-initializes `extents_` with `other.extents()`.

```
template<class OtherExtents>
  constexpr explicit(see below)
    mapping(const layout_stride::mapping<OtherExtents>& other);
```

13 *Constraints*: `is_constructible_v<extents_type, OtherExtents>` is `true`.

14 *Preconditions*:

(14.1) — If `extents_type::rank() > 0` is `true`, then for all r in the range $[0, \texttt{extents\_type::rank()})$, `other.stride(`$r$`)` equals `other.extents().`*`fwd-prod-of-extents`*`(`$r$`)`, and

(14.2) — `other.required_span_size()` is representable as a value of type `index_type` (6.9.2).

15 *Effects*: Direct-non-list-initializes *`extents_`* with `other.extents()`.

16 *Remarks*: The expression inside `explicit` is equivalent to:

```
!(extents_type::rank() == 0 && is_convertible_v<OtherExtents, extents_type>)
```

23.7.3.4.5.3 Observers [mdspan.layout.left.obs]

```
constexpr index_type required_span_size() const noexcept;
```

1 *Returns*: `extents().`*`fwd-prod-of-extents`*`(extents_type::rank())`.

```
template<class... Indices>
  constexpr index_type operator()(Indices... i) const noexcept;
```

2 *Constraints*:

(2.1) — `sizeof...(Indices) == extents_type::rank()` is `true`,

(2.2) — `(is_convertible_v<Indices, index_type> && ...)` is `true`, and

(2.3) — `(is_nothrow_constructible_v<index_type, Indices> && ...)` is `true`.

3 *Preconditions*: `extents_type::`*`index-cast`*`(i)` is a multidimensional index in *`extents_`* (23.7.3.1).

4 *Effects*: Let `P` be a parameter pack such that

```
is_same_v<index_sequence_for<Indices...>, index_sequence<P...>>
```

is `true`. Equivalent to:

```
return ((static_cast<index_type>(std::move(i)) * stride(P)) + ... + 0);
```

```
constexpr index_type stride(rank_type i) const noexcept;
```

5 *Constraints*: `extents_type::rank() > 0` is `true`.

6 *Preconditions*: `i < extents_type::rank()` is `true`.

7 *Returns*: `extents().`*`fwd-prod-of-extents`*`(i)`.

```
template<class OtherExtents>
  friend constexpr bool operator==(const mapping& x, const mapping<OtherExtents>& y) noexcept;
```

8 *Constraints*: `extents_type::rank() == OtherExtents::rank()` is `true`.

9 *Effects*: Equivalent to: `return x.extents() == y.extents();`

23.7.3.4.6 Class template `layout_right::mapping` [mdspan.layout.right]

23.7.3.4.6.1 Overview [mdspan.layout.right.overview]

1 `layout_right` provides a layout mapping where the rightmost extent is stride 1, and strides increase right-to-left as the product of extents.

```
namespace std {
  template<class Extents>
  class layout_right::mapping {
  public:
    using extents_type = Extents;
    using index_type = extents_type::index_type;
    using size_type = extents_type::size_type;
    using rank_type = extents_type::rank_type;
    using layout_type = layout_right;
```

```
    // 23.7.3.4.6.2, constructors
    constexpr mapping() noexcept = default;
    constexpr mapping(const mapping&) noexcept = default;
    constexpr mapping(const extents_type&) noexcept;
    template<class OtherExtents>
      constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
        mapping(const mapping<OtherExtents>&) noexcept;
    template<class OtherExtents>
      constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
        mapping(const layout_left::mapping<OtherExtents>&) noexcept;
    template<class LayoutRightPaddedMapping>
      constexpr explicit(!is_convertible_v<typename LayoutRightPaddedMapping::extents_type,
                                           extents_type>)
        mapping(const LayoutRightPaddedMapping&) noexcept;
    template<class OtherExtents>
      constexpr explicit(see below)
        mapping(const layout_stride::mapping<OtherExtents>&) noexcept;

    constexpr mapping& operator=(const mapping&) noexcept = default;

    // 23.7.3.4.6.3, observers
    constexpr const extents_type& extents() const noexcept { return extents_; }

    constexpr index_type required_span_size() const noexcept;

    template<class... Indices>
      constexpr index_type operator()(Indices...) const noexcept;

    static constexpr bool is_always_unique() noexcept { return true; }
    static constexpr bool is_always_exhaustive() noexcept { return true; }
    static constexpr bool is_always_strided() noexcept { return true; }

    static constexpr bool is_unique() noexcept { return true; }
    static constexpr bool is_exhaustive() noexcept { return true; }
    static constexpr bool is_strided() noexcept { return true; }

    constexpr index_type stride(rank_type) const noexcept;

    template<class OtherExtents>
      friend constexpr bool operator==(const mapping&, const mapping<OtherExtents>&) noexcept;

  private:
    extents_type extents_{};     // exposition only

    // 23.7.3.7.7, submdspan mapping specialization
    template<class... SliceSpecifiers>
      constexpr auto submdspan-mapping-impl(SliceSpecifiers...) const       // exposition only
        -> see below;

    template<class... SliceSpecifiers>
      friend constexpr auto submdspan_mapping(
        const mapping& src, SliceSpecifiers... slices) {
          return src.submdspan-mapping-impl(slices...);
        }
  };
}
```

2 If `Extents` is not a specialization of `extents`, then the program is ill-formed.

3 `layout_right::mapping<E>` is a trivially copyable type that models `regular` for each `E`.

4 *Mandates*: If `Extents::rank_dynamic() == 0` is `true`, then the size of the multidimensional index space `Extents()` is representable as a value of type `typename Extents::index_type`.

23.7.3.4.6.2 Constructors [mdspan.layout.right.cons]

```
constexpr mapping(const extents_type& e) noexcept;
```

1 *Preconditions*: The size of the multidimensional index space `e` is representable as a value of type `index_type` (6.9.2).

2 *Effects*: Direct-non-list-initializes *`extents_`* with `e`.

```
template<class OtherExtents>
  constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
    mapping(const mapping<OtherExtents>& other) noexcept;
```

3 *Constraints*: `is_constructible_v<extents_type, OtherExtents>` is `true`.

4 *Preconditions*: `other.required_span_size()` is representable as a value of type `index_type` (6.9.2).

5 *Effects*: Direct-non-list-initializes *`extents_`* with `other.extents()`.

```
template<class OtherExtents>
  constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
    mapping(const layout_left::mapping<OtherExtents>& other) noexcept;
```

6 *Constraints*:

(6.1) — `extents_type::rank() <= 1` is `true`, and

(6.2) — `is_constructible_v<extents_type, OtherExtents>` is `true`.

7 *Preconditions*: `other.required_span_size()` is representable as a value of type `index_type` (6.9.2).

8 *Effects*: Direct-non-list-initializes *`extents_`* with `other.extents()`.

```
template<class LayoutRightPaddedMapping>
  constexpr explicit(!is_convertible_v<typename LayoutRightPaddedMapping::extents_type,
                                       extents_type>)
    mapping(const LayoutRightPaddedMapping&) noexcept;
```

9 *Constraints*:

(9.1) — *`is-layout-right-padded-mapping-of`*`<LayoutRightPaddedMapping>` is `true`.

(9.2) — `is_constructible_v<extents_type, typename LayoutRightPaddedMapping::extents_type>` is `true`.

10 *Mandates*: If

(10.1) — `Extents::rank()` is greater than one,

(10.2) — `Extents::static_extent(Extents::rank() - 1)` does not equal `dynamic_extent`, and

(10.3) — `LayoutRightPaddedMapping::`*`static-padding-stride`* does not equal `dynamic_extent`,

then `Extents::static_extent(Extents::rank() - 1)` equals `LayoutRightPaddedMapping::`*`static-padding-stride`*.

11 *Preconditions*:

(11.1) — If `extents_type::rank() > 1` is `true`, then `other.stride(extents_type::rank() - 2)` equals `other.extents().extent(extents_type::rank() - 1)`.

(11.2) — `other.required_span_size()` is representable as a value of type `index_type`.

12 *Effects*: Direct-non-list-initializes `extents_` with `other.extents()`.

```
template<class OtherExtents>
  constexpr explicit(see below)
    mapping(const layout_stride::mapping<OtherExtents>& other) noexcept;
```

13 *Constraints*: `is_constructible_v<extents_type, OtherExtents>` is `true`.

14 *Preconditions*:

(14.1) — If `extents_type::rank() > 0` is `true`, then for all r in the range $[0, \texttt{extents\_type::rank()})$, `other.stride(`$r$`)` equals `other.extents().`*`rev-prod-of-extents`*`(`$r$`)`.

(14.2) — `other.required_span_size()` is representable as a value of type `index_type` (6.9.2).

15 *Effects*: Direct-non-list-initializes *extents_* with `other.extents()`.

16 *Remarks*: The expression inside `explicit` is equivalent to:

```
!(extents_type::rank() == 0 && is_convertible_v<OtherExtents, extents_type>)
```

23.7.3.4.6.3 Observers [mdspan.layout.right.obs]

```
constexpr index_type required_span_size() const noexcept;
```

1 *Returns*: `extents().`*`fwd-prod-of-extents`*`(extents_type::rank())`.

```
template<class... Indices>
  constexpr index_type operator()(Indices... i) const noexcept;
```

2 *Constraints*:

(2.1) — `sizeof...(Indices) == extents_type::rank()` is `true`,

(2.3) — `(is_nothrow_constructible_v<index_type, Indices> && ...)` is `true`.

3 *Preconditions*: `extents_type::`*`index-cast`*`(i)` is a multidimensional index in *extents_* (23.7.3.1).

4 *Effects*: Let `P` be a parameter pack such that

```
is_same_v<index_sequence_for<Indices...>, index_sequence<P...>>
```

is `true`. Equivalent to:

```
return ((static_cast<index_type>(std::move(i)) * stride(P)) + ... + 0);
```

```
constexpr index_type stride(rank_type i) const noexcept;
```

5 *Constraints*: `extents_type::rank() > 0` is `true`.

6 *Preconditions*: `i < extents_type::rank()` is `true`.

7 *Returns*: `extents().`*`rev-prod-of-extents`*`(i)`.

```
template<class OtherExtents>
  friend constexpr bool operator==(const mapping& x, const mapping<OtherExtents>& y) noexcept;
```

8 *Constraints*: `extents_type::rank() == OtherExtents::rank()` is `true`.

9 *Effects*: Equivalent to: `return x.extents() == y.extents();`

23.7.3.4.7 Class template `layout_stride::mapping` [mdspan.layout.stride]

23.7.3.4.7.1 Overview [mdspan.layout.stride.overview]

1 `layout_stride` provides a layout mapping where the strides are user-defined.

```
namespace std {
  template<class Extents>
  class layout_stride::mapping {
  public:
    using extents_type = Extents;
    using index_type = extents_type::index_type;
    using size_type = extents_type::size_type;
    using rank_type = extents_type::rank_type;
    using layout_type = layout_stride;

  private:
    static constexpr rank_type rank_ = extents_type::rank();     // exposition only

  public:
    // 23.7.3.4.7.3, constructors
    constexpr mapping() noexcept;
    constexpr mapping(const mapping&) noexcept = default;
    template<class OtherIndexType>
      constexpr mapping(const extents_type&, span<OtherIndexType, rank_>) noexcept;
    template<class OtherIndexType>
      constexpr mapping(const extents_type&, const array<OtherIndexType, rank_>&) noexcept;
```

```
    template<class StridedLayoutMapping>
      constexpr explicit(see below) mapping(const StridedLayoutMapping&) noexcept;

    constexpr mapping& operator=(const mapping&) noexcept = default;

    // 23.7.3.4.7.4, observers
    constexpr const extents_type& extents() const noexcept { return extents_; }
    constexpr array<index_type, rank_> strides() const noexcept { return strides_; }

    constexpr index_type required_span_size() const noexcept;

    template<class... Indices>
      constexpr index_type operator()(Indices...) const noexcept;

    static constexpr bool is_always_unique() noexcept { return true; }
    static constexpr bool is_always_exhaustive() noexcept;
    static constexpr bool is_always_strided() noexcept { return true; }

    static constexpr bool is_unique() noexcept { return true; }
    constexpr bool is_exhaustive() const noexcept;
    static constexpr bool is_strided() noexcept { return true; }

    constexpr index_type stride(rank_type i) const noexcept { return strides_[i]; }

    template<class OtherMapping>
      friend constexpr bool operator==(const mapping&, const OtherMapping&) noexcept;

  private:
    extents_type extents_{};                    // exposition only
    array<index_type, rank_> strides_{};        // exposition only

    // 23.7.3.7.7, submdspan mapping specialization
    template<class... SliceSpecifiers>
      constexpr auto submdspan-mapping-impl(SliceSpecifiers...) const       // exposition only
        -> see below;

    template<class... SliceSpecifiers>
      friend constexpr auto submdspan_mapping(
        const mapping& src, SliceSpecifiers... slices) {
          return src.submdspan-mapping-impl(slices...);
      }
  };
}
```

2 If `Extents` is not a specialization of `extents`, then the program is ill-formed.

3 `layout_stride::mapping<E>` is a trivially copyable type that models `regular` for each `E`.

4 *Mandates*: If `Extents::rank_dynamic() == 0` is `true`, then the size of the multidimensional index space `Extents()` is representable as a value of type `typename Extents::index_type`.

23.7.3.4.7.2 Exposition-only helpers [mdspan.layout.stride.expo]

1 Let *REQUIRED-SPAN-SIZE*`(e, strides)` be:

(1.1) — `1`, if `e.rank() == 0` is `true`,

(1.2) — otherwise `0`, if the size of the multidimensional index space `e` is 0,

(1.3) — otherwise `1` plus the sum of products of `(e.extent(`r`) - 1)` and

`extents_type::`*index-cast*`(strides[`r`])`

for all r in the range $[0, \texttt{e.rank()})$.

2 Let *OFFSET*`(m)` be:

(2.1) — `m()`, if `e.rank() == 0` is `true`,

(2.2) — otherwise `0`, if the size of the multidimensional index space `e` is 0,

(2.3) — otherwise `m(z...)` for a pack of integers `z` that is a multidimensional index in `m.extents()` and each element of `z` equals 0.

3 Let *`is-extents`* be the exposition-only variable template defined as follows:

```
template<class T>
  constexpr bool is-extents = false;                                  // exposition only
template<class IndexType, size_t... Args>
  constexpr bool is-extents<extents<IndexType, Args...>> = true;      // exposition only
```

4 Let *`layout-mapping-alike`* be the exposition-only concept defined as follows:

```
template<class M>
concept layout-mapping-alike = requires {                             // exposition only
  requires is-extents<typename M::extents_type>;
  { M::is_always_strided() } -> same_as<bool>;
  { M::is_always_exhaustive() } -> same_as<bool>;
  { M::is_always_unique() } -> same_as<bool>;
  bool_constant<M::is_always_strided()>::value;
  bool_constant<M::is_always_exhaustive()>::value;
  bool_constant<M::is_always_unique()>::value;
};
```

[*Note 1*: This concept checks that the functions `M::is_always_strided()`, `M::is_always_exhaustive()`, and `M::is_always_unique()` exist, are constant expressions, and have a return type of `bool`. — *end note*]

23.7.3.4.7.3 Constructors [mdspan.layout.stride.cons]

```
constexpr mapping() noexcept;
```

1 *Preconditions*: `layout_right::mapping<extents_type>().required_span_size()` is representable as a value of type `index_type` (6.9.2).

2 *Effects*: Direct-non-list-initializes *`extents_`* with `extents_type()`, and for all d in the range $[0, $ *`rank_`*$)$, direct-non-list-initializes *`strides_`*`[`d`]` with `layout_right::mapping<extents_type>().stride(`d`)`.

```
template<class OtherIndexType>
  constexpr mapping(const extents_type& e, span<OtherIndexType, rank_> s) noexcept;
template<class OtherIndexType>
  constexpr mapping(const extents_type& e, const array<OtherIndexType, rank_>& s) noexcept;
```

3 *Constraints*:

(3.1) — `is_convertible_v<const OtherIndexType&, index_type>` is `true`, and

(3.2) — `is_nothrow_constructible_v<index_type, const OtherIndexType&>` is `true`.

4 *Preconditions*:

(4.1) — The result of converting `s[`i`]` to `index_type` is greater than `0` for all i in the range $[0, $ *`rank_`*$)$.

(4.2) — *`REQUIRED-SPAN-SIZE`*`(e, s)` is representable as a value of type `index_type` (6.9.2).

(4.3) — If *`rank_`* is greater than 0, then there exists a permutation P of the integers in the range $[0, $ *`rank_`*$)$, such that `s[`p_i`] >= s[`p_{i-1}`] * e.extent(`p_{i-1}`)` is `true` for all i in the range $[1, $ *`rank_`*$)$, where p_i is the i^{th} element of P.

[*Note 1*: For `layout_stride`, this condition is necessary and sufficient for `is_unique()` to be `true`. — *end note*]

5 *Effects*: Direct-non-list-initializes *`extents_`* with `e`, and for all d in the range $[0, $ *`rank_`*$)$, direct-non-list-initializes `strides_[`d`]` with `as_const(s[`d`])`.

```
template<class StridedLayoutMapping>
  constexpr explicit(see below)
    mapping(const StridedLayoutMapping& other) noexcept;
```

6 *Constraints*:

(6.1) — *`layout-mapping-alike`*`<StridedLayoutMapping>` is satisfied.

(6.2) — `is_constructible_v<extents_type, typename StridedLayoutMapping::extents_type>` is `true`.

(6.3) — `StridedLayoutMapping::is_always_unique()` is `true`.

(6.4) — `StridedLayoutMapping::is_always_strided()` is `true`.

7 *Preconditions*:

(7.1) — `StridedLayoutMapping` meets the layout mapping requirements (23.7.3.4.2),

(7.2) — `other.stride(`r`) > 0` is `true` for every rank index r of `extents()`,

(7.3) — `other.required_span_size()` is representable as a value of type `index_type` (6.9.2), and

(7.4) — *`OFFSET`*`(other) == 0` is `true`.

8 *Effects*: Direct-non-list-initializes *`extents_`* with `other.extents()`, and for all d in the range $[0,$ *`rank_`*$)$, direct-non-list-initializes *`strides_`*`[`d`]` with `other.stride(`d`)`.

9 Remarks: The expression inside `explicit` is equivalent to:

```
!(is_convertible_v<typename StridedLayoutMapping::extents_type, extents_type> &&
  (is-mapping-of<layout_left, StridedLayoutMapping> ||
   is-mapping-of<layout_right, StridedLayoutMapping> ||
   is-layout-left-padded-mapping-of<StridedLayoutMapping> ||
   is-layout-right-padded-mapping-of<StridedLayoutMapping> ||
   is-mapping-of<layout_stride, StridedLayoutMapping>))
```

23.7.3.4.7.4 Observers [mdspan.layout.stride.obs]

```
constexpr index_type required_span_size() const noexcept;
```

1 *Returns*: *`REQUIRED-SPAN-SIZE`*`(extents(), strides_)`.

```
template<class... Indices>
  constexpr index_type operator()(Indices... i) const noexcept;
```

2 *Constraints*:

(2.1) — `sizeof...(Indices) ==` *`rank_`* is `true`,

(2.2) — `(is_convertible_v<Indices, index_type> && ...)` is `true`, and

(2.3) — `(is_nothrow_constructible_v<index_type, Indices> && ...)` is `true`.

3 *Preconditions*: `extents_type::`*`index-cast`*`(i)` is a multidimensional index in *`extents_`* (23.7.3.1).

4 *Effects*: Let `P` be a parameter pack such that

```
is_same_v<index_sequence_for<Indices...>, index_sequence<P...>>
```

is `true`. Equivalent to:

```
return ((static_cast<index_type>(std::move(i)) * stride(P)) + ... + 0);
```

```
static constexpr bool is_always_exhaustive() noexcept;
```

5 *Returns*: `true` if *`rank_`* is 0 or if there is a rank index `r` of `extents()` such that `extents_type::static_extent(r)` is 0, otherwise `false`.

```
constexpr bool is_exhaustive() const noexcept;
```

6 *Returns*:

(6.1) — `true` if *`rank_`* or the size of the multidimensional index space `m.extents()` is 0.

(6.2) — Otherwise, `true` if there is a permutation P of the integers in the range $[0,$ *`rank_`*$)$ such that `stride(`p_0`)` equals 1, and `stride(`p_i`)` equals `stride(`p_{i-1}`) * extents().extent(`p_{i-1}`)` for i in the range $[1,$ *`rank_`*$)$, where p_i is the i^{th} element of P.

(6.3) — Otherwise, `false`.

```
template<class OtherMapping>
  friend constexpr bool operator==(const mapping& x, const OtherMapping& y) noexcept;
```

7 *Constraints*:

(7.1) — *`layout-mapping-alike`*`<OtherMapping>` is satisfied.

(7.2) — *`rank_`* `== OtherMapping::extents_type::rank()` is `true`.

(7.3) — `OtherMapping::is_always_strided()` is `true`.

8 *Preconditions*: `OtherMapping` meets the layout mapping requirements (23.7.3.4.3).

9 *Returns*: `true` if `x.extents() == y.extents()` is `true`, *`OFFSET`*`(y) == 0` is `true`, and each of `x.stride(`r`) == y.stride(`r`)` is `true` for r in the range $[0, $`x.extents().rank()`$)$. Otherwise, `false`.

23.7.3.4.8 Class template `layout_left_padded::mapping` [mdspan.layout.leftpad]

23.7.3.4.8.1 Overview [mdspan.layout.leftpad.overview]

1 `layout_left_padded` provides a layout mapping that behaves like `layout_left::mapping`, except that the padding stride `stride(1)` can be greater than or equal to `extent(0)`.

```
namespace std {
  template<size_t PaddingValue>
  template<class Extents>
  class layout_left_padded<PaddingValue>::mapping {
  public:
    static constexpr size_t padding_value = PaddingValue;

    using extents_type = Extents;
    using index_type = extents_type::index_type;
    using size_type = extents_type::size_type;

    }
  };
}
```

2 If `Extents` is not a specialization of `extents`, then the program is ill-formed.

3 `layout_left_padded::mapping<E>` is a trivially copyable type that models `regular` for each `E`.

4 Throughout 23.7.3.4.8, let `P_rank` be the following size *rank_* parameter pack of `size_t` values:

(4.1) — the empty parameter pack, if *rank_* equals zero;

(4.2) — otherwise, `0zu`, if *rank_* equals one;

(4.3) — otherwise, the parameter pack `0zu`, `1zu`, ..., *rank_*`- 1`.

5 *Mandates*:

(5.1) — If `rank_dynamic() == 0` is `true`, then the size of the multidimensional index space `Extents()` is representable as a value of type `index_type`.

(5.2) — If `padding_value` is not equal to `dynamic_extent`, then `padding_value` is representable as a value of type `index_type`.

(5.3) — If

(5.3.1) — *rank_* is greater than one,

(5.3.2) — `padding_value` does not equal `dynamic_extent`, and

(5.3.3) — *first-static-extent* does not equal `dynamic_extent`,

then *LEAST-MULTIPLE-AT-LEAST*`(padding_value, `*first-static-extent*`)` is representable as a value of type `size_t`, and is representable as a value of type `index_type`.

(5.4) — If

(5.4.1) — *rank_* is greater than one,

(5.4.2) — `padding_value` does not equal `dynamic_extent`, and

(5.4.3) — `extents_type::static_extent(`k`)` does not equal `dynamic_extent` for all k in the range [`0`, `extents_type::rank()`),

then the product of *LEAST-MULTIPLE-AT-LEAST*`(padding_value, ext.static_extent(0))` and all values `ext.static_extent(`k`)` with k in the range of [`1`, *rank_*) is representable as a value of type `size_t`, and is representable as a value of type `index_type`.

23.7.3.4.8.2 Exposition-only members [mdspan.layout.leftpad.expo]

```
static constexpr size_t static-padding-stride = see below;
```

1 The value is

(1.1) — 0, if *rank_* equals zero or one;

(1.2) — otherwise, dynamic_extent, if padding_value or *first-static-extent* equals dynamic_extent;

(1.3) — otherwise, the size_t value which is *LEAST-MULTIPLE-AT-LEAST*(padding_value, *first-static-extent*).

```
index_type stride-1 = static-padding-stride;
```

2 *Recommended practice*: Implementations should not store this value if *static-padding-stride* is not dynamic_extent.

[*Note 1*: Using extents<index_type, *static-padding-stride*> instead of index_type as the type of *stride-1* would achieve this. — *end note*]

23.7.3.4.8.3 Constructors [mdspan.layout.leftpad.cons]

```
constexpr mapping(const extents_type& ext);
```

1 *Preconditions*:

(1.1) — The size of the multidimensional index space ext is representable as a value of type index_type.

(1.2) — If *rank_* is greater than one and padding_value does not equal dynamic_extent, then *LEAST-MULTIPLE-AT-LEAST*(padding_value, ext.extent(0)) is representable as a value of type *index_type*.

(1.3) — If *rank_* is greater than one and padding_value does not equal dynamic_extent, then the product of *LEAST-MULTIPLE-AT-LEAST*(padding_value, ext.extent(0)) and all values ext.extent(k) with k in the range of $[1, rank\_)$ is representable as a value of type index_type.

2 *Effects*:

(2.1) — Direct-non-list-initializes *extents_* with ext; and

(2.2) — if *rank_* is greater than one, direct-non-list-initializes *stride-1*

(2.2.1) — with ext.extent(0) if padding_value is dynamic_extent,

(2.2.2) — otherwise with *LEAST-MULTIPLE-AT-LEAST*(padding_value, ext.extent(0)).

```
template<class OtherIndexType>
constexpr mapping(const extents_type& ext, OtherIndexType padding);
```

3 Let pad be extents_type::*index-cast*(std::move(padding)).

4 *Constraints*:

(4.1) — is_convertible_v<OtherIndexType, index_type> is true.

(4.2) — is_nothrow_constructible_v<index_type, OtherIndexType> is true.

5 *Preconditions*:

(5.1) — pad is representable as a value of type index_type.

(5.2) — pad is greater than zero.

(5.3) — If *rank_* is greater than one, then *LEAST-MULTIPLE-AT-LEAST*(pad, ext.extent(0)) is representable as a value of type index_type.

(5.4) — If *rank_* is greater than one, then the product of *LEAST-MULTIPLE-AT-LEAST*(pad, ext.extent(0)) and all values ext.extent(k) with k in the range of $[1, rank\_)$ is representable as a value of type index_type.

(5.5) — If padding_value is not equal to dynamic_extent, padding_value equals pad.

6 *Effects*: Direct-non-list-initializes *extents_* with ext, and if *rank_* is greater than one, direct-non-list-initializes *stride-1* with *LEAST-MULTIPLE-AT-LEAST*(pad, ext.extent(0)).

```
template<class OtherExtents>
  constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
    mapping(const layout_left::mapping<OtherExtents>& other);
```

7 *Constraints*: is_constructible_v<extents_type, OtherExtents> is true.

8 *Mandates*: If OtherExtents::rank() is greater than 1, then

```
(static-padding-stride == dynamic_extent) ||
(OtherExtents::static_extent(0) == dynamic_extent) ||
(static-padding-stride == OtherExtents::static_extent(0))
```

is `true`.

9 *Preconditions*:

(9.1) — If `extents_type::rank() > 1` is `true` and `padding_value == dynamic_extent` is `false`, then `other.stride(1)` equals

```
LEAST-MULTIPLE-AT-LEAST(padding_value,
                        extents_type::index-cast(other.extents().extent(0)))
```

and

(9.2) — `other.required_span_size()` is representable as a value of type `index_type`.

10 *Effects*: Equivalent to `mapping(other.extents())`.

```
template<class OtherExtents>
  constexpr explicit(see below)
    mapping(const layout_stride::mapping<OtherExtents>& other);
```

11 *Constraints*: `is_constructible_v<extents_type, OtherExtents>` is `true`.

12 *Preconditions*:

(12.1) — If *rank_* is greater than `1` and `padding_value` does not equal `dynamic_extent`, then `other.stride(1)` equals

```
LEAST-MULTIPLE-AT-LEAST(padding_value,
                        extents_type::index-cast(other.extents().extent(0)))
```

(12.2) — If *rank_* is greater than 0, then `other.stride(0)` equals 1.

(12.3) — If *rank_* is greater than 2, then for all r in the range $[2, rank\_)$, `other.stride(r)` equals

```
(other.extents().fwd-prod-of-extents(r) / other.extents().extent(0)) * other.stride(1)
```

(12.4) — `other.required_span_size()` is representable as a value of type *index_type*.

13 *Effects*:

(13.1) — Direct-non-list-initializes *extents_* with `other.extents()` and

(13.2) — if *rank_* is greater than one, direct-non-list-initializes *stride-1* with `other.stride(1)`.

14 *Remarks*: The expression inside `explicit` is equivalent to:

```
!(rank_ == 0 && is_convertible_v<OtherExtents, extents_type>)
```

```
template<class LayoutLeftPaddedMapping>
  constexpr explicit(see below)
    mapping(const LayoutLeftPaddedMapping& other);
```

15 *Constraints*:

(15.1) — *is-layout-left-padded-mapping-of*<LayoutLeftPaddedMapping> is `true`.

(15.2) — `is_constructible_v<extents_type, typename LayoutLeftPaddedMapping::extents_type>` is `true`.

16 *Mandates*: If *rank_* is greater than 1, then

```
padding_value == dynamic_extent ||
LayoutLeftPaddedMapping::padding_value == dynamic_extent ||
padding_value == LayoutLeftPaddedMapping::padding_value
```

is `true`.

17 *Preconditions*:

(17.1) — If *rank_* is greater than 1 and `padding_value` does not equal `dynamic_extent`, then `other.stride(1)` equals

```
LEAST-MULTIPLE-AT-LEAST(padding_value,
                        extents_type::index-cast(other.extent(0)))
```

(17.2) — `other.required_span_size()` is representable as a value of type `index_type`.

18 *Effects*:

(18.1) — Direct-non-list-initializes *extents_* with `other.extents()` and

(18.2) — if *rank_* is greater than one, direct-non-list-initializes *stride-1* with `other.stride(1)`.

19 *Remarks*: The expression inside `explicit` is equivalent to:

```
!is_convertible_v<typename LayoutLeftPaddedMapping::extents_type, extents_type> ||
rank_> 1 &&
(padding_value != dynamic_extent ||
 LayoutLeftPaddedMapping::padding_value == dynamic_extent)
```

```
template<class LayoutRightPaddedMapping>
  constexpr explicit(see below)
    mapping(const LayoutRightPaddedMapping& other) noexcept;
```

20 *Constraints*:

(20.1) — *is-layout-right-padded-mapping-of*<LayoutRightPaddedMapping> is `true` or *is-mapping-of*<layout_right, LayoutRightPaddedMapping> is `true`.

(20.2) — *rank_* equals zero or one.

(20.3) — `is_constructible_v<extents_type, typename LayoutRightPaddedMapping::extents_type>` is `true`.

21 *Preconditions*: `other.required_span_size()` is representable as a value of type `index_type`.

22 *Effects*: Direct-non-list-initializes *extents_* with `other.extents()`.

23 *Remarks*: The expression inside `explicit` is equivalent to:

```
!is_convertible_v<typename LayoutRightPaddedMapping::extents_type, extents_type>
```

[*Note 1*: Neither the input mapping nor the mapping to be constructed uses the padding stride in the rank-0 or rank-1 case, so the padding stride does not affect either the constraints or the preconditions. — *end note*]

23.7.3.4.8.4 Observers [mdspan.layout.leftpad.obs]

```
constexpr array<index_type, rank_> strides() const noexcept;
```

1 *Returns*: `array<index_type, rank_>({stride(P_rank)...})`.

```
constexpr index_type required_span_size() const noexcept;
```

2 *Returns*:

(2.1) — `0` if the multidimensional index space *extents_* is empty,

(2.2) — otherwise, `(*this)(extents_.extent(P_rank) - index_type(1)...) + 1`.

```
template<class... Indices>
constexpr index_type operator()(Indices... idxs) const noexcept;
```

3 *Constraints*:

(3.1) — `sizeof...(Indices) == rank_` is `true`.

(3.2) — `(is_convertible_v<Indices, index_type> && ...)` is `true`.

(3.3) — `(is_nothrow_constructible_v<index_type, Indices> && ...)` is `true`.

4 *Preconditions*: `extents_type::index_cast(idxs)` is a multidimensional index in `extents()` (23.7.3.1).

5 *Returns*: `((static_cast<index_type>(std::move(idxs)) * stride(P_rank)) + ... + 0)`.

```
static constexpr bool is_always_exhaustive() noexcept;
```

6 *Returns*:

(6.1) — If *rank_* equals zero or one, then `true`;

(6.2) — otherwise, if neither *static-padding-stride* nor *first-static-extent* equal `dynamic_extent`, then *static-padding-stride* == *first-static-extent*;

(6.3) — otherwise, `false`.

```
constexpr bool is_exhaustive() const noexcept;
```

7 *Returns*: `true` if *`rank_`* equals zero or one; otherwise, `extents_.extent(0) == stride(1)`.

```
constexpr index_type stride(rank_type r) const noexcept;
```

8 *Preconditions*: `r` is smaller than *`rank_`*.

9 *Returns*:

(9.1) — If `r` equals zero: 1;

(9.2) — otherwise, if `r` equals one: *`stride-1`*;

(9.3) — otherwise, the product of *`stride-1`* and all values `extents_.extent(`k`)` with k in the range $[1, \texttt{r})$.

```
template<class LayoutLeftPaddedMapping>
  friend constexpr bool operator==(const mapping& x, const LayoutLeftPaddedMapping& y) noexcept;
```

10 *Constraints*:

(10.1) — *`is-layout-left-padded-mapping-of`*`<LayoutLeftPaddedMapping>` is `true`.

(10.2) — `LayoutLeftPaddedMapping::extents_type::rank() == rank_` is `true`.

11 *Returns*: `true` if `x.extents() == y.extents()` is `true` and *`rank_`* `< 2 || x.stride(1) == y.stride(1)` is `true`. Otherwise, `false`.

23.7.3.4.9 Class template `layout_right_padded::mapping` [mdspan.layout.rightpad]

23.7.3.4.9.1 Overview [mdspan.layout.rightpad.overview]

1 `layout_right_padded` provides a layout mapping that behaves like `layout_right::mapping`, except that the padding stride `stride(extents_type::rank() - 2)` can be greater than or equal to `extents_type::extent(extents_type::rank() - 1)`.

```
namespace std {
  template<size_t PaddingValue>
  template<class Extents>
  class layout_right_padded<PaddingValue>::mapping {
  public:
    static constexpr size_t padding_value = PaddingValue;

    using extents_type = Extents;
    using index_type = extents_type::index_type;
    using size_type = extents_type::size_type;
    using rank_type = extents_type::rank_type;
    using layout_type = layout_right_padded<PaddingValue>;

  private:
    static constexpr size_t rank_ = extents_type::rank();     // exposition only
    static constexpr size_t last-static-extent =              // exposition only
      extents_type::static_extent(rank_ - 1);

    // 23.7.3.4.9.2, exposition-only members
    static constexpr size_t static-padding-stride = see below; // exposition only

  public:
    // 23.7.3.4.9.3, constructors
    constexpr mapping() noexcept : mapping(extents_type{}) {}
    constexpr mapping(const mapping&) noexcept = default;
    constexpr mapping(const extents_type&);
    template<class OtherIndexType>
      constexpr mapping(const extents_type&, OtherIndexType);

    template<class OtherExtents>
      constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
        mapping(const layout_right::mapping<OtherExtents>&);
    template<class OtherExtents>
      constexpr explicit(see below)
        mapping(const layout_stride::mapping<OtherExtents>&);
```

```
    template<class LayoutRightPaddedMapping>
      constexpr explicit(see below)
        mapping(const LayoutRightPaddedMapping&);
    template<class LayoutLeftPaddedMapping>
      constexpr explicit(see below)
        mapping(const LayoutLeftPaddedMapping&) noexcept;

    constexpr mapping& operator=(const mapping&) noexcept = default;

    // 23.7.3.4.9.4, observers
    constexpr const extents_type& extents() const noexcept { return extents_; }
    constexpr array<index_type, rank_> strides() const noexcept;

    constexpr index_type required_span_size() const noexcept;

    template<class... Indices>
      constexpr index_type operator()(Indices...) const noexcept;

    static constexpr bool is_always_unique() noexcept { return true; }
    static constexpr bool is_always_exhaustive() noexcept;
    static constexpr bool is_always_strided() noexcept { return true; }

    static constexpr bool is_unique() noexcept { return true; }
    constexpr bool is_exhaustive() const noexcept;
    static constexpr bool is_strided() noexcept { return true; }

    constexpr index_type stride(rank_type) const noexcept;

    template<class LayoutRightPaddedMapping>
      friend constexpr bool operator==(const mapping&, const LayoutRightPaddedMapping&) noexcept;

  private:
    // 23.7.3.4.9.2, exposition-only members
    index_type stride-rm2 = static-padding-stride;                    // exposition only
    extents_type extents_{};                                          // exposition only

    // 23.7.3.7.7, submdspan mapping specialization
    template<class... SliceSpecifiers>
      constexpr auto submdspan-mapping-impl(SliceSpecifiers...) const  // exposition only
        -> see below;

    template<class... SliceSpecifiers>
      friend constexpr auto submdspan_mapping(const mapping& src, SliceSpecifiers... slices) {
      return src.submdspan-mapping-impl(slices...);
    }
  };
}
```

2 If `Extents` is not a specialization of `extents`, then the program is ill-formed.

3 `layout_right_padded::mapping<E>` is a trivially copyable type that models `regular` for each `E`.

4 Throughout 23.7.3.4.9, let `P_rank` be the following size ***rank_*** parameter pack of `size_t` values:

(4.1) — the empty parameter pack, if ***rank_*** equals zero;

(4.2) — otherwise, `0zu`, if ***rank_*** equals one;

(4.3) — otherwise, the parameter pack `0zu`, `1zu`, ..., ***rank_*** `- 1`.

5 *Mandates*:

(5.1) — If `rank_dynamic() == 0` is `true`, then the size of the multidimensional index space `Extents()` is representable as a value of type `index_type`.

(5.2) — If `padding_value` is not equal to `dynamic_extent`, then `padding_value` is representable as a value of type `index_type`.

(5.3) — If

(5.3.1) — *rank_* is greater than one,

(5.3.2) — padding_value does not equal dynamic_extent, and

(5.3.3) — *last-static-extent* does not equal dynamic_extent,

then *LEAST-MULTIPLE-AT-LEAST*(padding_value, *last-static-extent*) is representable as a value of type size_t, and is representable as a value of type index_type.

(5.4) — If

(5.4.1) — *rank_* is greater than one,

(5.4.2) — padding_value does not equal dynamic_extent, and

(5.4.3) — extents_type::static_extent(k) does not equal dynamic_extent for all k in the range [0, *rank_*),

then the product of *LEAST-MULTIPLE-AT-LEAST*(padding_value, ext.static_extent(*rank_* - 1)) and all values ext.static_extent(k) with k in the range of [0, *rank_* - 1) is representable as a value of type size_t, and is representable as a value of type index_type.

23.7.3.4.9.2 Exposition-only members [mdspan.layout.rightpad.expo]

```
static constexpr size_t static-padding-stride = see below;
```

1 The value is

(1.1) — 0, if *rank_* equals zero or one;

(1.2) — otherwise, dynamic_extent, if padding_value or *last-static-extent* equals dynamic_extent;

(1.3) — otherwise, the size_t value which is *LEAST-MULTIPLE-AT-LEAST*(padding_value, *last-static-extent*).

```
index_type stride-rm2 = static-padding-stride;
```

2 *Recommended practice*: Implementations should not store this value if *static-padding-stride* is not dynamic_extent.

[*Note 1*: Using extents<index_type, *static-padding-stride*> instead of index_type as the type of *stride-rm2* would achieve this. — *end note*]

23.7.3.4.9.3 Constructors [mdspan.layout.rightpad.cons]

```
constexpr mapping(const extents_type& ext);
```

1 *Preconditions*:

(1.1) — The size of the multidimensional index space ext is representable as a value of type index_type.

(1.2) — If *rank_* is greater than one and padding_value does not equal dynamic_extent, then *LEAST-MULTIPLE-AT-LEAST*(padding_value, ext.extent(*rank_* - 1)) is representable as a value of type *index_type*.

(1.3) — If *rank_* is greater than one and padding_value does not equal dynamic_extent, then the product of *LEAST-MULTIPLE-AT-LEAST*(padding_value, ext.extent(*rank_* - 1)) and all values ext.extent(k) with k in the range of [0, *rank_* - 1) is representable as a value of type index_type.

2 *Effects*:

(2.1) — Direct-non-list-initializes *extents_* with ext; and

(2.2) — if *rank_* is greater than one, direct-non-list-initializes *stride-rm2*

(2.2.1) — with ext.extent(*rank_* - 1) if padding_value is dynamic_extent,

(2.2.2) — otherwise with *LEAST-MULTIPLE-AT-LEAST*(padding_value, ext.extent(*rank_* - 1)).

```
template<class OtherIndexType>
constexpr mapping(const extents_type& ext, OtherIndexType padding);
```

3 Let pad be extents_type::*index-cast*(std::move(padding)).

4 *Constraints*:

(4.1) — is_convertible_v<OtherIndexType, index_type> is true.

(4.2) — `is_nothrow_constructible_v<index_type, OtherIndexType>` is `true`.

5 *Preconditions*:

(5.1) — `pad` is representable as a value of type `index_type`.

(5.2) — `pad` is greater than zero.

(5.3) — If *`rank_`* is greater than one, then *`LEAST-MULTIPLE-AT-LEAST`*`(pad, ext.extent(`*`rank_`*` - 1))` is representable as a value of type `index_type`.

(5.4) — If *`rank_`* is greater than one, then the product of *`LEAST-MULTIPLE-AT-LEAST`*`(pad, ext.extent(`*`rank_`*` - 1))` and all values `ext.extent(`k`)` with k in the range of $[0,$ *`rank_`*` - 1)` is representable as a value of type `index_type`.

(5.5) — If `padding_value` is not equal to `dynamic_extent`, `padding_value` equals `pad`.

6 *Effects*: Direct-non-list-initializes *`extents_`* with `ext`, and if *`rank_`* is greater than one, direct-non-list-initializes *`stride-rm2`* with *`LEAST-MULTIPLE-AT-LEAST`*`(pad, ext.extent(`*`rank_`*` - 1))`.

```
template<class OtherExtents>
  constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
    mapping(const layout_right::mapping<OtherExtents>& other);
```

7 *Constraints*: `is_constructible_v<extents_type, OtherExtents>` is `true`.

8 *Mandates*: If `OtherExtents::rank()` is greater than 1, then

```
(static-padding-stride == dynamic_extent) ||
(OtherExtents::static_extent(rank_ - 1) == dynamic_extent) ||
(static-padding-stride == OtherExtents::static_extent(rank_ - 1))
```

is `true`.

9 *Preconditions*:

(9.1) — If *`rank_`*` > 1` is `true` and `padding_value == dynamic_extent` is `false`, then `other.stride(`*`rank_`*` - 2)` equals

```
LEAST-MULTIPLE-AT-LEAST(padding_value,
                        extents_type::index-cast(other.extents().extent(rank_ - 1)))
```

and

(9.2) — `other.required_span_size()` is representable as a value of type `index_type`.

10 *Effects*: Equivalent to `mapping(other.extents())`.

```
template<class OtherExtents>
  constexpr explicit(see below)
    mapping(const layout_stride::mapping<OtherExtents>& other);
```

11 *Constraints*: `is_constructible_v<extents_type, OtherExtents>` is `true`.

12 *Preconditions*:

(12.1) — If *`rank_`* is greater than 1 and `padding_value` does not equal `dynamic_extent`, then `other.stride(`*`rank_`*` - 2)` equals

```
LEAST-MULTIPLE-AT-LEAST(padding_value,
                        extents_type::index-cast(other.extents().extent(rank_ - 1)))
```

(12.2) — If *`rank_`* is greater than 0, then other.stride(*`rank_`* - 1) equals 1.

(12.3) — If *`rank_`* is greater than 2, then for all r in the range $[0,$ *`rank_`*` - 2)`, `other.stride(`r`)` equals

```
(other.extents().rev-prod-of-extents(r) / other.extents().extent(rank_ - 1)) *
  other.stride(rank_ - 2)
```

(12.4) — `other.required_span_size()` is representable as a value of type `index_type`.

13 *Effects*:

(13.1) — Direct-non-list-initializes *`extents_`* with `other.extents()`; and

(13.2) — if *`rank_`* is greater than one, direct-non-list-initializes *`stride-rm2`* with `other.stride(`*`rank_`*` - 2)`.

14 *Remarks*: The expression inside `explicit` is equivalent to:

```
!(rank_ == 0 && is_convertible_v<OtherExtents, extents_type>)
```

```
template<class LayoutRightPaddedMapping>
  constexpr explicit(see below)
    mapping(const LayoutRightPaddedMapping& other);
```

15 *Constraints*:

(15.1) — *is-layout-right-padded-mapping-of*<LayoutRightPaddedMapping> is `true`.

(15.2) — `is_constructible_v<extents_type, typename LayoutRightPaddedMapping::extents_type>` is `true`.

16 *Mandates*: If *rank_* is greater than 1, then

```
padding_value == dynamic_extent ||
LayoutRightPaddedMapping::padding_value == dynamic_extent ||
padding_value == LayoutRightPaddedMapping::padding_value
```

is `true`.

17 *Preconditions*:

(17.1) — If *rank_* is greater than 1 and `padding_value` does not equal `dynamic_extent`, then `other.stride(`*rank_* `- 2)` equals

```
LEAST-MULTIPLE-AT-LEAST(padding_value,
                        extents_type::index-cast(other.extent(rank_ - 1)))
```

(17.2) — `other.required_span_size()` is representable as a value of type `index_type`.

18 *Effects*:

(18.1) — Direct-non-list-initializes *extents_* with `other.extents()`; and

(18.2) — if *rank_* is greater than one, direct-non-list-initializes *stride-rm2* with `other.stride(rank_ - 2)`.

19 *Remarks*: The expression inside `explicit` is equivalent to:

```
!is_convertible_v<typename LayoutRightPaddedMapping::extents_type, extents_type> ||
rank_ > 1 &&
(padding_value != dynamic_extent ||
 LayoutRightPaddedMapping::padding_value == dynamic_extent)
```

```
template<class LayoutLeftPaddedMapping>
  constexpr explicit(see below)
    mapping(const LayoutLeftPaddedMapping& other) noexcept;
```

20 *Constraints*:

(20.1) — *is-layout-left-padded-mapping-of*<LayoutLeftPaddedMapping> is `true` or *is-mapping-of*<layout_left, LayoutLeftPaddedMapping> is `true`.

(20.2) — *rank_* equals zero or one.

(20.3) — `is_constructible_v<extents_type, typename LayoutLeftPaddedMapping::extents_type>` is `true`.

21 *Preconditions*: `other.required_span_size()` is representable as a value of type `index_type`.

22 *Effects*: Direct-non-list-initializes *extents_* with `other.extents()`.

23 *Remarks*: The expression inside `explicit` is equivalent to:

```
!is_convertible_v<typename LayoutLeftPaddedMapping::extents_type, extents_type>
```

[*Note 1*: Neither the input mapping nor the mapping to be constructed uses the padding stride in the rank-0 or rank-1 case, so the padding stride affects neither the constraints nor the preconditions. — *end note*]

23.7.3.4.9.4 Observers [mdspan.layout.rightpad.obs]

```
constexpr array<index_type, rank_> strides() const noexcept;
```

1 *Returns*: `array<index_type, rank_>(stride(P_rank)...)`.

```
constexpr index_type required_span_size() const noexcept;
```

2 *Returns*: `0` if the multidimensional index space *`extents_`* is empty, otherwise `(*this)(`*`extents_`*`.extent(P_rank) - index_type(1)...) + 1`.

```
template<class... Indices>
constexpr index_type operator()(Indices... idxs) const noexcept;
```

3 *Constraints*:

(3.1) — `sizeof...(Indices) ==` *`rank_`* is `true`.

(3.2) — `(is_convertible_v<Indices, index_type> && ...)` is `true`.

(3.3) — `(is_nothrow_constructible_v<index_type, Indices> && ...)` is `true`.

4 *Preconditions*: `extents_type::`*`index-cast`*`(idxs)` is a multidimensional index in `extents()` (23.7.3.1).

5 *Returns*: `((static_cast<index_type>(std::move(idxs)) * stride(P_rank)) + ... + 0)`.

```
static constexpr bool is_always_exhaustive() noexcept;
```

6 *Returns*:

(6.1) — If *`rank_`* equals zero or one, then `true`;

(6.2) — otherwise, if neither *`static-padding-stride`* nor *`last-static-extent`* equal `dynamic_extent`, then *`static-padding-stride == last-static-extent`*;

(6.3) — otherwise, `false`.

```
constexpr bool is_exhaustive() const noexcept;
```

7 *Returns*: `true` if *`rank_`* equals zero or one; otherwise,

`extents_``.extent(`*`rank_`*` - 1) == stride(`*`rank_`*` - 2)`

```
constexpr index_type stride(rank_type r) const noexcept;
```

8 *Preconditions*: `r` is smaller than *`rank_`*.

9 *Returns*:

(9.1) — If `r` equals *`rank_`*` - 1`: `1`;

(9.2) — otherwise, if `r` equals *`rank_`*` - 2`: *`stride-rm2`*;

(9.3) — otherwise, the product of *`stride-rm2`* and all values `extents_.extent(`k`)` with k in the range of [`r + 1`, *`rank_`*` - 1`).

```
template<class LayoutRightPaddedMapping>
  friend constexpr bool operator==(const mapping& x, const LayoutRightPaddedMapping& y) noexcept;
```

10 *Constraints*:

(10.1) — *`is-layout-right-padded-mapping-of`*`<LayoutRightPaddedMapping>` is `true`.

(10.2) — `LayoutRightPaddedMapping::extents_type::rank() ==` *`rank_`* is `true`.

11 *Returns*: `true` if `x.extents() == y.extents()` is `true` and *`rank_`*` < 2 || x.stride(`*`rank_`*` - 2) == y.stride(`*`rank_`*` - 2)` is `true`. Otherwise, `false`.

23.7.3.5 Accessor policy [mdspan.accessor]

23.7.3.5.1 General [mdspan.accessor.general]

1 An *accessor policy* defines types and operations by which a reference to a single object is created from an abstract data handle to a number of such objects and an index.

2 A range of indices $[0, N)$ is an *accessible range* of a given data handle and an accessor if, for each i in the range, the accessor policy's `access` function produces a valid reference to an object.

3 In 23.7.3.5.2,

(3.1) — `A` denotes an accessor policy.

(3.2) — `a` denotes a value of type `A` or `const A`.

(3.3) — `p` denotes a value of type `A::data_handle_type` or `const A::data_handle_type`.

[*Note 1*: The type `A::data_handle_type` need not be dereferenceable. — *end note*]

(3.4) — `n`, `i`, and `j` each denote values of type `size_t`.

23.7.3.5.2 Requirements [mdspan.accessor.reqmts]

1 A type `A` meets the accessor policy requirements if

(1.1) — `A` models `copyable`,

(1.2) — `is_nothrow_move_constructible_v<A>` is `true`,

(1.3) — `is_nothrow_move_assignable_v<A>` is `true`,

(1.4) — `is_nothrow_swappable_v<A>` is `true`, and

(1.5) — the following types and expressions are well-formed and have the specified semantics.

`typename A::element_type`

2 *Result*: A complete object type that is not an abstract class type.

`typename A::data_handle_type`

3 *Result*: A type that models `copyable`, and for which `is_nothrow_move_constructible_v<A::data_handle_type>` is `true`, `is_nothrow_move_assignable_v<A::data_handle_type>` is `true`, and `is_nothrow_swappable_v<A::data_handle_type>` is `true`.

[*Note 1*: The type of `data_handle_type` need not be `element_type*`. — *end note*]

`typename A::reference`

4 *Result*: A type that models `common_reference_with<A::reference&&, A::element_type&>`.

[*Note 2*: The type of `reference` need not be `element_type&`. — *end note*]

`typename A::offset_policy`

5 *Result*: A type `OP` such that:

(5.1) — `OP` meets the accessor policy requirements,

(5.2) — `constructible_from<OP, const A&>` is modeled, and

(5.3) — `is_same_v<typename OP::element_type, typename A::element_type>` is `true`.

`a.access(p, i)`

6 *Result*: `A::reference`

7 *Remarks*: The expression is equality preserving.

8 [*Note 3*: Concrete accessor policies can impose preconditions for their `access` function. However, they might not. For example, an accessor where `p` is `span<A::element_type, dynamic_extent>` and `access(p, i)` returns `p[i % p.size()]` does not need to impose a precondition on `i`. — *end note*]

`a.offset(p, i)`

9 *Result*: `A::offset_policy::data_handle_type`

10 *Returns*: `q` such that for `b` being `A::offset_policy(a)`, and any integer `n` for which $[0, \texttt{n})$ is an accessible range of `p` and `a`:

(10.1) — $[0, \texttt{n} - \texttt{i})$ is an accessible range of `q` and `b`; and

(10.2) — `b.access(q, j)` provides access to the same element as `a.access(p, i + j)`, for every `j` in the range $[0, \texttt{n} - \texttt{i})$.

11 *Remarks*: The expression is equality-preserving.

23.7.3.5.3 Class template `default_accessor` [mdspan.accessor.default]

23.7.3.5.3.1 Overview [mdspan.accessor.default.overview]

```
namespace std {
  template<class ElementType>
  struct default_accessor {
    using offset_policy = default_accessor;
    using element_type = ElementType;
```

```
    using reference = ElementType&;
    using data_handle_type = ElementType*;

    constexpr default_accessor() noexcept = default;
    template<class OtherElementType>
      constexpr default_accessor(default_accessor<OtherElementType>) noexcept;
    constexpr reference access(data_handle_type p, size_t i) const noexcept;
    constexpr data_handle_type offset(data_handle_type p, size_t i) const noexcept;
  };
}
```

1 `default_accessor` meets the accessor policy requirements.

2 `ElementType` is required to be a complete object type that is neither an abstract class type nor an array type.

3 Each specialization of `default_accessor` is a trivially copyable type that models `semiregular`.

4 $[0, n)$ is an accessible range for an object `p` of type `data_handle_type` and an object of type `default_accessor` if and only if $[\texttt{p}, \texttt{p + } n)$ is a valid range.

23.7.3.5.3.2 Members [mdspan.accessor.default.members]

```
template<class OtherElementType>
  constexpr default_accessor(default_accessor<OtherElementType>) noexcept {}
```

1 *Constraints*: `is_convertible_v<OtherElementType(*)[], element_type(*)[]>` is `true`.

```
constexpr reference access(data_handle_type p, size_t i) const noexcept;
```

2 *Effects*: Equivalent to: `return p[i];`

```
constexpr data_handle_type offset(data_handle_type p, size_t i) const noexcept;
```

3 *Effects*: Equivalent to: `return p + i;`

23.7.3.5.4 Class template aligned_accessor [mdspan.accessor.aligned]

23.7.3.5.4.1 Overview [mdspan.accessor.aligned.overview]

```
namespace std {
  template<class ElementType, size_t ByteAlignment>
  struct aligned_accessor {
    using offset_policy = default_accessor<ElementType>;
    using element_type = ElementType;
    using reference = ElementType&;
    using data_handle_type = ElementType*;

    static constexpr size_t byte_alignment = ByteAlignment;

    constexpr aligned_accessor() noexcept = default;
    template<class OtherElementType, size_t OtherByteAlignment>
      constexpr aligned_accessor(
        aligned_accessor<OtherElementType, OtherByteAlignment>) noexcept;
    template<class OtherElementType>
      constexpr explicit aligned_accessor(default_accessor<OtherElementType>) noexcept;

    template<class OtherElementType>
      constexpr operator default_accessor<OtherElementType>() const noexcept;

    constexpr reference access(data_handle_type p, size_t i) const noexcept;

    constexpr typename offset_policy::data_handle_type offset(
      data_handle_type p, size_t i) const noexcept;
  };
}
```

1 *Mandates*:

(1.1) — `byte_alignment` is a power of two, and

(1.2) — `byte_alignment >= alignof(ElementType)` is `true`.

2 `aligned_accessor` meets the accessor policy requirements.

3 `ElementType` is required to be a complete object type that is neither an abstract class type nor an array type.

4 Each specialization of `aligned_accessor` is a trivially copyable type that models `semiregular`.

5 $[0, n)$ is an accessible range for an object `p` of type `data_handle_type` and an object of type `aligned_accessor` if and only if

(5.1) — $[$`p`$,$ `p + n`$)$ is a valid range, and,

(5.2) — if n is greater than zero, then `is_sufficiently_aligned<byte_alignment>(p)` is `true`.

6 [*Example 1*: The following function `compute` uses `is_sufficiently_aligned` to check whether a given `mdspan` with `default_accessor` has a data handle with sufficient alignment to be used with `aligned_accessor<float, 4 * sizeof(float)>`. If so, the function dispatches to a function `compute_using_fourfold_overalignment` that requires fourfold over-alignment of arrays, but can therefore use hardware-specific instructions, such as four-wide SIMD (Single Instruction Multiple Data) instructions. Otherwise, `compute` dispatches to a possibly less optimized function `compute_without_requiring_overalignment` that has no over-alignment requirement.

```
void compute_using_fourfold_overalignment(
  mdspan<float, dims<1>, layout_right, aligned_accessor<float, 4 * alignof(float)>> x);

void compute_without_requiring_overalignment(
  mdspan<float, dims<1>, layout_right> x);

void compute(mdspan<float, dims<1>> x) {
  constexpr auto byte_alignment = 4 * sizeof(float);
  auto accessor = aligned_accessor<float, byte_alignment>{};
  auto x_handle = x.data_handle();

  if (is_sufficiently_aligned<byte_alignment>(x_handle)) {
    compute_using_fourfold_overalignment(mdspan{x_handle, x.mapping(), accessor});
  } else {
    compute_without_requiring_overalignment(x);
  }
}
```

— *end example*]

23.7.3.5.4.2 Members [mdspan.accessor.aligned.members]

```
template<class OtherElementType, size_t OtherByteAlignment>
  constexpr aligned_accessor(aligned_accessor<OtherElementType, OtherByteAlignment>) noexcept;
```

1 *Constraints*:

(1.1) — `is_convertible_v<OtherElementType(*)[], element_type(*)[]>` is `true`.

(1.2) — `OtherByteAlignment >= byte_alignment` is `true`.

2 *Effects*: None.

```
template<class OtherElementType>
  constexpr explicit aligned_accessor(default_accessor<OtherElementType>) noexcept;
```

3 *Constraints*: `is_convertible_v<OtherElementType(*)[], element_type(*)[]>` is `true`.

4 *Effects*: None.

```
constexpr reference access(data_handle_type p, size_t i) const noexcept;
```

5 *Preconditions*: $[$`0, i + 1`$)$ is an accessible range for `p` and `*this`.

6 *Effects*: Equivalent to: `return assume_aligned<byte_alignment>(p)[i];`

```
template<class OtherElementType>
  constexpr operator default_accessor<OtherElementType>() const noexcept;
```

7 *Constraints*: `is_convertible_v<element_type(*)[], OtherElementType(*)[]>` is `true`.

8 *Effects*: Equivalent to: `return {};`

```
constexpr typename offset_policy::data_handle_type
  offset(data_handle_type p, size_t i) const noexcept;
```

9 *Preconditions*: $[0, \texttt{i + 1})$ is an accessible range for `p` and `*this`.

10 *Effects*: Equivalent to: `return assume_aligned<byte_alignment>(p) + i;`

23.7.3.6 Class template `mdspan` [mdspan.mdspan]

23.7.3.6.1 Overview [mdspan.mdspan.overview]

1 `mdspan` is a view of a multidimensional array of elements.

```
namespace std {
  template<class ElementType, class Extents, class LayoutPolicy = layout_right,
           class AccessorPolicy = default_accessor<ElementType>>
  class mdspan {
  public:
    using extents_type = Extents;
    using layout_type = LayoutPolicy;
    using accessor_type = AccessorPolicy;
    using mapping_type = layout_type::template mapping<extents_type>;
    using element_type = ElementType;
    using value_type = remove_cv_t<element_type>;
    using index_type = extents_type::index_type;
    using size_type = extents_type::size_type;
    using rank_type = extents_type::rank_type;
    using data_handle_type = accessor_type::data_handle_type;
    using reference = accessor_type::reference;

    static constexpr rank_type rank() noexcept { return extents_type::rank(); }
    static constexpr rank_type rank_dynamic() noexcept { return extents_type::rank_dynamic(); }
    static constexpr size_t static_extent(rank_type r) noexcept
      { return extents_type::static_extent(r); }
    constexpr index_type extent(rank_type r) const noexcept { return extents().extent(r); }

    // 23.7.3.6.2, constructors
    constexpr mdspan();
    constexpr mdspan(const mdspan& rhs) = default;
    constexpr mdspan(mdspan&& rhs) = default;

    template<class... OtherIndexTypes>
      constexpr explicit mdspan(data_handle_type ptr, OtherIndexTypes... exts);

      -> mdspan<typename AccessorType::element_type, typename MappingType::extents_type,
                typename MappingType::layout_type, AccessorType>;
}
```

2 *Mandates*:

(2.1) — `ElementType` is a complete object type that is neither an abstract class type nor an array type,

(2.2) — `Extents` is a specialization of `extents`, and

(2.3) — `is_same_v<ElementType, typename AccessorPolicy::element_type>` is `true`.

3 `LayoutPolicy` shall meet the layout mapping policy requirements (23.7.3.4.3), and `AccessorPolicy` shall meet the accessor policy requirements (23.7.3.5.2).

4 Each specialization `MDS` of `mdspan` models `copyable` and

(4.1) — `is_nothrow_move_constructible_v<MDS>` is `true`,

(4.2) — `is_nothrow_move_assignable_v<MDS>` is `true`, and

(4.3) — `is_nothrow_swappable_v<MDS>` is `true`.

5 A specialization of `mdspan` is a trivially copyable type if its `accessor_type`, `mapping_type`, and `data_handle_type` are trivially copyable types.

23.7.3.6.2 Constructors [mdspan.mdspan.cons]

```
constexpr mdspan();
```

1 *Constraints*:

(1.1) — `rank_dynamic() > 0` is `true`.

(1.2) — `is_default_constructible_v<data_handle_type>` is `true`.

(1.3) — `is_default_constructible_v<mapping_type>` is `true`.

(1.4) — `is_default_constructible_v<accessor_type>` is `true`.

2 *Preconditions*: $[0, map\_.\texttt{required\_span\_size}())$ is an accessible range of *ptr_* and *acc_* for the values of *map_* and *acc_* after the invocation of this constructor.

3 *Effects*: Value-initializes *ptr_*, *map_*, and *acc_*.

```
template<class... OtherIndexTypes>
  constexpr explicit mdspan(data_handle_type p, OtherIndexTypes... exts);
```

4 Let `N` be `sizeof...(OtherIndexTypes)`.

5 *Constraints*:

(5.1) — `(is_convertible_v<OtherIndexTypes, index_type> && ...)` is `true`,

(5.2) — `(is_nothrow_constructible_v<index_type, OtherIndexTypes> && ...)` is `true`,

(5.3) — `N == rank() || N == rank_dynamic()` is `true`,

(5.4) — `is_constructible_v<mapping_type, extents_type>` is `true`, and

(5.5) — `is_default_constructible_v<accessor_type>` is `true`.

6 *Preconditions*: $[0, \textit{map\_}.\texttt{required\_span\_size}())$ is an accessible range of `p` and *`acc_`* for the values of *`map_`* and *`acc_`* after the invocation of this constructor.

7 *Effects*:

(7.1) — Direct-non-list-initializes *`ptr_`* with `std::move(p)`,

(7.2) — direct-non-list-initializes *`map_`* with `extents_type(static_cast<index_type>(std::move(exts))...)`, and

(7.3) — value-initializes *`acc_`*.

```
template<class OtherIndexType, size_t N>
  constexpr explicit(N != rank_dynamic())
    mdspan(data_handle_type p, span<OtherIndexType, N> exts);
template<class OtherIndexType, size_t N>
  constexpr explicit(N != rank_dynamic())
    mdspan(data_handle_type p, const array<OtherIndexType, N>& exts);
```

8 *Constraints*:

(8.1) — `is_convertible_v<const OtherIndexType&, index_type>` is `true`,

(8.2) — `is_nothrow_constructible_v<index_type, const OtherIndexType&>` is `true`,

(8.3) — `N == rank() || N == rank_dynamic()` is `true`,

(8.4) — `is_constructible_v<mapping_type, extents_type>` is `true`, and

(8.5) — `is_default_constructible_v<accessor_type>` is `true`.

9 *Preconditions*: $[0, \textit{map\_}.\texttt{required\_span\_size}())$ is an accessible range of `p` and *`acc_`* for the values of *`map_`* and *`acc_`* after the invocation of this constructor.

10 *Effects*:

(10.1) — Direct-non-list-initializes *`ptr_`* with `std::move(p)`,

(10.2) — direct-non-list-initializes *`map_`* with `extents_type(exts)`, and

(10.3) — value-initializes *`acc_`*.

```
constexpr mdspan(data_handle_type p, const extents_type& ext);
```

11 *Constraints*:

(11.1) — `is_constructible_v<mapping_type, const extents_type&>` is `true`, and

(11.2) — `is_default_constructible_v<accessor_type>` is `true`.

12 *Preconditions*: $[0, \textit{map\_}.\texttt{required\_span\_size}())$ is an accessible range of `p` and *`acc_`* for the values of *`map_`* and *`acc_`* after the invocation of this constructor.

13 *Effects*:

(13.1) — Direct-non-list-initializes *`ptr_`* with `std::move(p)`,

(13.2) — direct-non-list-initializes *`map_`* with `ext`, and

(13.3) — value-initializes *`acc_`*.

```
constexpr mdspan(data_handle_type p, const mapping_type& m);
```

14 *Constraints*: `is_default_constructible_v<accessor_type>` is `true`.

15 *Preconditions*: $[0, \texttt{m.required\_span\_size}())$ is an accessible range of `p` and *`acc_`* for the value of *`acc_`* after the invocation of this constructor.

16 *Effects*:

(16.1) — Direct-non-list-initializes *`ptr_`* with `std::move(p)`,

(16.2) — direct-non-list-initializes *`map_`* with `m`, and

(16.3) — value-initializes *`acc_`*.

```
constexpr mdspan(data_handle_type p, const mapping_type& m, const accessor_type& a);
```

17 *Preconditions*: $[0, \texttt{m.required\_span\_size}())$ is an accessible range of `p` and `a`.

18 *Effects*:

(18.1) — Direct-non-list-initializes *ptr_* with `std::move(p)`,

(18.2) — direct-non-list-initializes *map_* with `m`, and

(18.3) — direct-non-list-initializes *acc_* with `a`.

```
template<class OtherElementType, class OtherExtents,
         class OtherLayoutPolicy, class OtherAccessor>
  constexpr explicit(see below)
    mdspan(const mdspan<OtherElementType, OtherExtents,
                        OtherLayoutPolicy, OtherAccessor>& other);
```

19 *Constraints*:

(19.1) — `is_constructible_v<mapping_type, const OtherLayoutPolicy::template mapping<OtherExtents>&>` is `true`, and

(19.2) — `is_constructible_v<accessor_type, const OtherAccessor&>` is `true`.

20 *Mandates*:

(20.1) — `is_constructible_v<data_handle_type, const OtherAccessor::data_handle_type&>` is `true`, and

(20.2) — `is_constructible_v<extents_type, OtherExtents>` is `true`.

21 *Preconditions*: $[0, $ *map_*`.required_span_size()`$)$ is an accessible range of *ptr_* and *acc_* for values of *ptr_*, *map_*, and *acc_* after the invocation of this constructor.

22 *Hardened preconditions*: For each rank index `r` of `extents_type`, `static_extent(r) == dynamic_extent || static_extent(r) == other.extent(r)` is `true`.

23 *Effects*:

(23.1) — Direct-non-list-initializes *ptr_* with `other.`*ptr_*,

(23.2) — direct-non-list-initializes *map_* with `other.`*map_*, and

(23.3) — direct-non-list-initializes *acc_* with `other.`*acc_*.

24 *Remarks*: The expression inside `explicit` is equivalent to:

```
!is_convertible_v<const OtherLayoutPolicy::template mapping<OtherExtents>&, mapping_type>
|| !is_convertible_v<const OtherAccessor&, accessor_type>
```

23.7.3.6.3 Members [mdspan.mdspan.members]

```
template<class... OtherIndexTypes>
  constexpr reference operator[](OtherIndexTypes... indices) const;
```

1 *Constraints*:

(1.1) — `(is_convertible_v<OtherIndexTypes, index_type> && ...)` is `true`,

(1.2) — `(is_nothrow_constructible_v<index_type, OtherIndexTypes> && ...)` is `true`, and

(1.3) — `sizeof...(OtherIndexTypes) == rank()` is `true`.

2 Let `I` be `extents_type::`*index-cast*`(std::move(indices))`.

3 *Hardened preconditions*: `I` is a multidimensional index in `extents()`.

[*Note 1*: This implies that *map_*`(I) < `*map_*`.required_span_size()` is `true`. — *end note*]

4 *Effects*: Equivalent to:

```
return acc_.access(ptr_, map_(static_cast<index_type>(std::move(indices))...));
```

```
template<class OtherIndexType>
  constexpr reference operator[](span<OtherIndexType, rank()> indices) const;
template<class OtherIndexType>
  constexpr reference operator[](const array<OtherIndexType, rank()>& indices) const;
```

5 *Constraints*:

(5.1) — `is_convertible_v<const OtherIndexType&, index_type>` is `true`, and

(5.2) — `is_nothrow_constructible_v<index_type, const OtherIndexType&>` is `true`.

6 *Effects*: Let `P` be a parameter pack such that

```
is_same_v<make_index_sequence<rank()>, index_sequence<P...>>
```

is `true`. Equivalent to:

```
return operator[](extents_type::index-cast(as_const(indices[P]))...);
```

```
template<class... OtherIndexTypes>
  constexpr reference at(OtherIndexTypes... indices) const;
```

7 *Constraints*:

(7.1) — `(is_convertible_v<OtherIndexTypes, index_type> && ...)` is `true`,

(7.2) — `(is_nothrow_constructible_v<index_type, OtherIndexTypes> && ...)` is `true`, and

(7.3) — `sizeof...(OtherIndexTypes) == rank()` is `true`.

8 Let `I` be `extents_type::index-cast(std::move(indices))`.

9 *Returns*: `(*this)[I...]`.

10 *Throws*: `out_of_range` if `I` is not a multidimensional index in `extents()`.

```
template<class OtherIndexType>
  constexpr reference at(span<OtherIndexType, rank()> indices) const;
template<class OtherIndexType>
  constexpr reference at(const array<OtherIndexType, rank()>& indices) const;
```

11 *Constraints*:

(11.1) — `is_convertible_v<const OtherIndexType&, index_type>` is `true`, and

(11.2) — `is_nothrow_constructible_v<index_type, const OtherIndexType&>` is `true`.

12 *Effects*: Let `P` be a parameter pack such that

```
is_same_v<make_index_sequence<rank()>, index_sequence<P...>>
```

is `true`. Equivalent to:

```
return at(extents_type::index-cast(as_const(indices[P]))...);
```

```
constexpr size_type size() const noexcept;
```

13 *Preconditions*: The size of the multidimensional index space `extents()` is representable as a value of type `size_type` (6.9.2).

14 *Returns*: `extents().fwd-prod-of-extents(rank())`.

```
constexpr bool empty() const noexcept;
```

15 *Returns*: `true` if the size of the multidimensional index space `extents()` is 0, otherwise `false`.

```
friend constexpr void swap(mdspan& x, mdspan& y) noexcept;
```

16 *Effects*: Equivalent to:

```
swap(x.ptr_, y.ptr_);
swap(x.map_, y.map_);
swap(x.acc_, y.acc_);
```

23.7.3.7 `submdspan` [mdspan.sub]

23.7.3.7.1 Overview [mdspan.sub.overview]

1 The `submdspan` facilities create a new `mdspan` viewing a subset of elements of an existing input `mdspan`. The subset viewed by the created `mdspan` is determined by the `SliceSpecifier` arguments.

2 Given a signed or unsigned integer type `IndexType`, a type S is a ***`submdspan`*** *slice type for* ***`IndexType`*** if at least one of the following holds:

(2.1) — `is_convertible_v<`S`, full_extent_t>` is `true`;

(2.2) — `is_convertible_v<`S`, IndexType>` is `true`;

(2.3) — S is a specialization of `extent_slice` and `is_convertible_v<`X`, IndexType>` is `true` for X denoting S`::offset_type`, S`::extent_type`, and S`::stride_type`;

(2.4) — S is a specialization of `range_slice` and `is_convertible_v<`X`, IndexType>` is `true` for X denoting type of S`::first`, S`::last`, and S`::stride` members; or

(2.5) — all of the following hold:

(2.5.1) — the declaration `auto [...ls] = std::move(s);` is well-formed for some object `s` of type S,

(2.5.2) — `sizeof...(ls)` is equal to 2, and

(2.5.3) — `(is_convertible_v<decltype(std::move(ls)), IndexType> && ...)` is `true`.

3 Given a signed or unsigned integer type `IndexType`, a type S is a *canonical* ***`submdspan`*** *index type for* ***`IndexType`*** if S is either `IndexType` or `constant_wrapper<v>` for some value `v` of type `IndexType`, such that `v` is greater than or equal to zero.

4 Given a signed or unsigned integer type `IndexType`, a type S is a *canonical* ***`submdspan`*** *slice type for* ***`IndexType`*** if exactly one of the following is `true`:

(4.1) — S is `full_extent_t`;

(4.2) — S is a canonical `submdspan` index type for `IndexType`; or

(4.3) — S is a specialization of `extent_slice` where all of the following hold:

(4.3.1) — `S::offset_type`, `S::extent_type`, and `S::stride_type` are all canonical `submdspan` index types for `IndexType`; and

(4.3.2) — if S`::stride_type` and S`::extent_type` are both specializations of `constant_wrapper`, then S`::stride_type::value` is greater than zero.

5 A type `S` is a *collapsing slice type* if it is neither `full_extent_t` nor a specialization of `extent_slice`.

[*Note 1*: Each collapsing slice type in `submdspan_mapping`'s parameter pack of slice specifier types reduces the rank of the result of `submdspan_mapping` by one. — *end note*]

6 A type `S` is a *unit-stride slice type* if

(6.1) — `S` is a specialization of `extent_slice` where `S::stride_type` is a specialization of `constant_wrapper` and `S::stride_type::value` is equal to 1, or

(6.2) — `S` denotes `full_extent_t`.

7 Given an object `e` of type `E` that is a specialization of `extents`, and an object `s` of type `S` that is a canonical `submdspan` slice type for `E::index_type`, the ***`submdspan`*** *slice range of* ***`s`*** *for the* k^{th} *extent of* ***`e`*** is:

(7.1) — $[0,$ `e.extent(`k`)`$)$, if `S` is `full_extent_t`;

(7.2) — [`E::index_type(s.offset)`, `E::index_type(s.offset)`), if `S` is a specialization of `extent_slice` and `E::index_type(s.extent)` is zero; otherwise

(7.3) — [`E::index_type(s.offset)`, `E::index_type(s.offset + 1 + (s.extent - 1) * s.stride)`), if `S` is a specialization of `extent_slice`; otherwise

(7.4) — [`E::index_type(s)`, `E::index_type(s)` $+ 1$)

8 Given a type `E` that is a specialization of `extents`, a type `S` is a *valid* ***`submdspan`*** *slice type for the* k^{th} *extent of* ***`E`*** if `S` is a canonical slice type for `E::index_type`, and for x equal to `E::static_extent(`k`)`, either x is equal to `dynamic_extent`; or

(8.1) — if `S` is a specialization of `extent_slice`, then

(8.1.1) — o is less than or equal to x;

(8.1.2) — e is less than or equal to x;

(8.1.3) — if e is greater than one, then t is greater than zero,

(8.1.4) — if e is greater than zero, then $o + 1 + (e - 1) * t$ is less than or equal to x,

where

(8.1.5) — o is the value of `S::offset_type::value` if `S::offset_type` is a specialization of `constant_wrapper` and `0` otherwise,

(8.1.6) — e is the value of `S::extent_type::value` if `S::extend_type` is a specialization of `constant_wrapper` and `0` otherwise,

(8.1.7) — t is the value of `S::stride_type::value` if `S::stride_type` is a specialization of `constant_wrapper` and `1` otherwise; and

(8.2) — if S is a specialization of `constant_wrapper`, then `S::value` is less than `x`.

9 Given an object `e` of type `E` that is a specialization of `extents` and an object `s` of type `S`, `s` is a *valid* ***`submdspan`*** *slice for the* k^{th} *extent of* `e` if

(9.1) — `S` is a valid `submdspan` slice type for the k^{th} extent of `E`;

(9.2) — the k^{th} interval of `e` contains the `submdspan` slice range of `s` for the k^{th} extent of `e`; and

(9.3) — if `S` is a specialization of `extent_slice`, then

(9.3.1) — `s.extent` is greater than or equal to zero, and

(9.3.2) — either `s.extent` is less than two or `s.stride` is greater than zero.

23.7.3.7.2 Range slices [mdspan.sub.range.slices]

1 `extent_slice` and `range_slice` represent a set of `extent` regularly spaced integer indices. The indices start at `offset` and `first`, respectively, and increase by increments of `stride`.

```
namespace std {
  template<class OffsetType, class ExtentType, class StrideType>
  struct extent_slice {
    using offset_type = OffsetType;
    using extent_type = ExtentType;
    using stride_type = StrideType;

    [[no_unique_address]] offset_type offset{};
    [[no_unique_address]] extent_type extent{};
    [[no_unique_address]] stride_type stride{};
  };

  template<class FirstType, class LastType, class StrideType = constant_wrapper<1zu>>
  struct range_slice {
    [[no_unique_address]] FirstType first{};
    [[no_unique_address]] LastType last{};
    [[no_unique_address]] StrideType stride{};
  };
}
```

2 `extent_slice` and `range_slice` have the data members and special members specified above. They have no base classes or members other than those specified.

3 *Mandates*: `OffsetType`, `ExtentType`, `FirstType`, `LastType`, and `StrideType` are signed or unsigned integer types, or model ***`integral-constant-like`***.

[*Note 1*: Both `extent_slice{.offset = 1, .extent = 4, .stride = 3}` and `range_slice{.first = 1, .last = 11, .stride = 3}` indicate the indices `1`, `4`, `7`, and `10`. Indices are selected from the half-open interval $[1, 1 + 10)$. — *end note*]

23.7.3.7.3 `submdspan_mapping_result` [mdspan.sub.map.result]

1 Specializations of `submdspan_mapping_result` are returned by overloads of `submdspan_mapping`.

```
namespace std {
  template<class LayoutMapping>
  struct submdspan_mapping_result {
    [[no_unique_address]] LayoutMapping mapping = LayoutMapping();
    size_t offset{};
  };
}
```

2 `submdspan_mapping_result` has the data members and special members specified above. It has no base classes or members other than those specified.

3 `LayoutMapping` shall meet the layout mapping requirements (23.7.3.4.3).

23.7.3.7.4 Exposition-only helpers [mdspan.sub.helpers]

1 For a pack `p` and an integer i, let ***`MAP_RANK`*****`(p, `** i**`)`** be the number of elements `p...[`j`]` for $0 \leq j < i$ whose types are not collapsing slice types.

```
template<class T>
  concept is-extent-slice = see below;
```

2 The concept *is-extent-slice*<T> is satisfied and modeled if and only if T is a specialization of extent_slice.

```
template<class T>
  concept is-range-slice = see below;
```

3 The concept *is-range-slice*<T> is satisfied and modeled if and only if T is a specialization of range_slice.

```
template<class IndexType, class S>
  constexpr auto canonical-index(S s);
```

4 *Mandates*: If S models *integral-constant-like*, then extents<IndexType>::*index-cast*(S::value) is representable as a value of type IndexType.

5 *Preconditions*: extents<IndexType>::*index-cast*(std::move(s)) is representable as a value of type IndexType.

6 *Effects*: Equivalent to:

(6.1) — return cw<IndexType(S::value)>; if S models *integral-constant-like*;

(6.2) — return IndexType(std::move(s)); otherwise.

```
template<class IndexType, class OffsetType, class SpanType, class... StrideTypes>
  constexpr auto canonical-range-slice(OffsetType offset, SpanType span, StrideTypes... strides);
```

7 Let

(7.1) — StrideType denote constant_wrapper<IndexType(1)> if StrideTypes is an empty pack or SpanType denotes constant_wrapper<IndexType(0)>, otherwise StrideTypes...[0];

(7.2) — stride be StrideType() if StrideType is a specialization of constant_wrapper, otherwise IndexType(1) if span == 0 is true, otherwise strides...[0];

(7.3) — *extent-value* be 1 + (span - 1) / stride if span != 0 is true, and 0 otherwise; and

(7.4) — let extent be cw<IndexType(*extent-value*)> if both SpanType and StrideType are specializations of constant_wrapper, and IndexType(*extent-value*) otherwise.

8 *Mandates*: sizeof...(StrideTypes) <= 1 is true, and if StrideType is a specialization of constant_wrapper, then StrideType::value > 0 is true.

9 *Preconditions*: stride > 0 is true.

10 *Returns*: extent_slice{.offset = offset, .extent = extent, .stride = stride}.

```
template<class IndexType, class S>
  constexpr auto canonical-slice(S s);
```

11 *Mandates*: S is a submdspan slice type for IndexType.

12 *Effects*: Equivalent to:

```
if constexpr (is_convertible_v<S, full_extent_t>) {
  return static_cast<full_extent_t>(std::move(s));
} else if constexpr (is_convertible_v<S, IndexType>) {
  return canonical-index<IndexType>(std::move(s));
} else if constexpr (is-extent-slice<S>) {
  return extent_slice{
    .offset = canonical-index<IndexType>(std::move(s.extent)),
    .extent = canonical-index<IndexType>(std::move(s.offset)),
    .stride = canonical-index<IndexType>(std::move(s.stride))
  };
} else if constexpr (is-range-slice<S>) {
  auto c_first = canonical-index<IndexType>(std::move(s.first));
  auto c_last  = canonical-index<IndexType>(std::move(s.last));
  return canonical-slice-range<IndexType>(
    c_first,
    canonical-index<IndexType>(c_last - c_first),
```

```
      canonical-index<IndexType>(std::move(s.stride)));
  } else {
    auto [s_first, s_last] = std::move(s);
    auto c_first = canonical-index<IndexType>(std::move(s_first));
    auto c_last  = canonical-index<IndexType>(std::move(s_last));
    return canonical-slice-range<IndexType>(
      c_first,
      canonical-index<IndexType>(c_last - c_first));
  }
```

23.7.3.7.5 submdspan slice canonicalization [mdspan.sub.canonical]

```
template<class IndexType, size_t... Extents, class... SliceSpecifiers>
  constexpr auto canonical_slices(const extents<IndexType, Extents...>& src,
                                  SliceSpecifiers... slices);
```

1 *Constraints*: `sizeof...(SliceSpecifiers)` equals `sizeof...(Extents)`.

2 *Mandates*: For each rank index k of `src`:

(2.1) — `SliceSpecifiers...[k]` is a `submdspan` slice type for `IndexType`, and

(2.2) — `decltype(canonical-slice<IndexType>(slices...[k]))` is a valid `submdspan` slice type for the k^{th} extent of `extents<IndexType, Extents...>`.

3 *Preconditions*: For each rank index k of `src`, `canonical-slice<IndexType>(slices...[k])` is a valid `submdspan` slice for the k^{th} extent of `src`.

4 *Returns*: `make_tuple(canonical-slice<IndexType>(slices)...)`.

23.7.3.7.6 subextents function [mdspan.sub.extents]

```
template<class IndexType, size_t... Extents, class... SliceSpecifiers>
  constexpr auto subextents(const extents<IndexType, Extents...>& src,
                            SliceSpecifiers... raw_slices);
```

1 Let `slices` be the pack introduced by the following declaration:

```
auto [...slices] = canonical_slices(src, raw_slices...);
```

2 *Constraints*: `sizeof...(SliceSpecifiers)` equals `sizeof...(Extents)`.

3 *Mandates*: For each rank index k of `src`:

(3.1) — `SliceSpecifiers...[`k`]` is a `submdspan` slice type for `IndexType`, and

(3.2) — `decltype(slices...[`k`])` is a valid `submdspan` slice type for the k^{th} extent of `extents<IndexType, Extents...>`.

4 *Preconditions*: For each rank index k of `src`, `slices...[`k`]` is a valid `submdspan` slice for the k^{th} extent of `src`.

5 Let `SubExtents` be a specialization of `extents` such that:

(5.1) — `SubExtents::rank()` equals *MAP_RANK*`(slices, Extents::rank())`; and

(5.2) — for each rank index k of `extents<IndexType, Extents...>` such that the type of `slices...[`k`]` is not a collapsing slice type, `SubExtents::static_extent(`*MAP_RANK*`(slices, `k`))` equals the following, where Σ_k denotes the type of `slices...[`k`]`:

(5.2.1) — `Extents::static_extent(`k`)` if Σ_k denotes `full_extent_t`; otherwise

(5.2.2) — Σ_k`::extent_type::value` if Σ_k is a specialization of `extent_slice` whose `extent_type` denotes a specialization of `constant_wrapper`;

(5.2.3) — otherwise, `dynamic_extent`.

6 *Returns*: A value `ext` of type `SubExtents` such that for each rank index k of `extents<IndexType, Extents...>`, where the type of `slices...[`k`]` is not a collapsing slice type, `ext.extent(`*MAP_RANK*`(slices, `k`))` equals the following, where σ_k denotes `slices...[`k`]`:

(6.1) — σ_k`.extent` if the type of σ_k is a specialization of `extent_slice`,

(6.2) — otherwise, $U - L$, where $[L, U)$ is the `submdspan` slice range of σ_k for the k^{th} extent of `src`.

23.7.3.7.7 Specializations of `submdspan_mapping` [mdspan.sub.map]

23.7.3.7.7.1 Sliceable layout mapping requirements [mdspan.sub.map.sliceable]

1 Let:

(1.1) — `M` denote a layout mapping class;

(1.2) — `IT` denote `M::extents_type::index_type`;

(1.3) — `m` denote a value of type (possibly const) `M`;

(1.4) — `M_rank` be equal to `M::extents_type::rank()`;

(1.5) — `valid_slices` denote a pack of (possibly const) objects for which `sizeof...(valid_slices) == M_rank` is `true` and, for each rank index i of `m.extents()`, `valid_slices...[`i`]` is a valid `submdspan` slice for the i^{th} extent of `m.extents()`;

(1.6) — `invalid_slices` denote a pack of objects for which `sizeof...(invalid_slices) == M_rank` is `true` and there exists an integer k such that the cv-unqualified type of `invalid_slices...[`k`]` is none of the following:

(1.6.1) — `IT`,

(1.6.2) — `full_extent_t`,

(1.6.3) — a specialization of `constant_wrapper`, or

(1.6.4) — a specialization of `extent_slice`.

2 For the purpose of this section, the meaning of `submdspan_mapping` is established as if by performing argument-dependent lookup only (6.5.4).

3 A type `M` meets the *sliceable layout mapping requirements* if

(3.1) — `M` meets the layout mapping requirements (23.7.3.4.3),

(3.2) — the expression `submdspan_mapping(m, invalid_slices...)` is ill-formed, and

(3.3) — the following expression is well-formed and has the specified semantics:

```
submdspan_mapping(m, valid_slices...)
```

4 *Result*: A type `SMR` that is a specialization of type `submdspan_mapping_result<SM>` for some type `SM` such that

(4.1) — `SM` meets the layout mapping requirements (23.7.3.4.3),

(4.2) — `SM::extents_type` is a specialization of `extents`,

(4.3) — `SM::extents_type::rank()` equals *`MAP_RANK`*`(valid_slices, M_rank)`, and

(4.4) — `SM::extents_type::index_type` denotes `IT`.

5 *Returns*: An object `smr` of type `SMR` such that

(5.1) — `smr.mapping.extents() == subextents(m.extents(), valid_slices...)` is `true`; and

(5.2) — for each integer pack `i` which is a multidimensional index in `smr.mapping.extents()`, `smr.mapping(i...) + smr.offset == m(j)` is `true`, where `j` is an integer pack such that

(5.2.1) — `sizeof...(j)` is equal to `M_rank`; and

(5.2.2) — for each rank index ρ of `m.extents()`, `j...[`ρ`]` is equal to the sum of

(5.2.2.1) — the lower bound of the `submdspan` slice range of `valid_slices...[`ρ`]` for extent ρ of `m.extents()`, and

(5.2.2.2) — zero if the type of `valid_slices...[`ρ`]` is a collapsing slice type, `i...[MAP_RANK(valid_slices,`ρ`)]` otherwise.

```
template<class LayoutMapping>
  concept sliceable-mapping = see below;
```

6 Let `lm` be an object of type `LayoutMapping` and let `fe` denote a pack of objects of type `full_extent_t` for which `sizeof...(fe) == LayoutMapping::extents_type::rank()` is `true`. A type `LayoutMapping` satisfies *`sliceable-mapping`* if

©ISO/IEC

(6.1) — the expression `submdspan_mapping(lm, fe...)` is well-formed when treated as an unevaluated operand, and

(6.2) — the type of that expression is a specialization of `submdspan_mapping_result`.

7 A type `LayoutMapping` models *`sliceable-mapping`* if `LayoutMapping` meets the sliceable layout mapping requirements.

23.7.3.7.7.2 Common [mdspan.sub.map.common]

1 The following elements apply to all functions in 23.7.3.7.7.

2 *Constraints*: `sizeof...(SliceSpecifiers)` equals `extents_type::rank()`.

3 *Mandates*: For each rank index k of `extents()`, `SliceSpecifiers...[`k`]` is a valid `submdspan` slice type for the k^{th} extent of `Extents`.

4 *Preconditions*: For each rank index k of `extents()`, `slices...[`k`]` is a valid slice for the k^{th} extent of `extents()`.

5 Let `sub_ext` be the result of `subextents(extents(), slices...)` and let `SubExtents` be `decltype(sub_ext)`.

6 Let `sub_strides` be an `array<SubExtents::index_type, SubExtents::rank()>` such that for each rank index k of `extents()` for which the type of `slices...[`k`]` is not a collapsing slice type, `sub_strides[`*`MAP_RANK`*`(slices,`k`)]` equals:

(6.1) — `stride(k) * s.stride` if the type of `s` is a specialization of `extent_slice` and `s.extent > 1` is `true`, where `s` is `slices...[`k`]`;

(6.2) — otherwise, `stride(`k`)`.

7 Let `ls` be a pack of values of `index_type`, where the ρ^{th} element equals the lower bound of the `submdspan` slice range of `slices...[`ρ`]` for extent ρ of `extents()`.

8 If `ls...[`k`]` equals `extents().extent(`k`)` for any rank index k of `extents()`, then let `offset` be a value of type `size_t` equal to `required_span_size()`. Otherwise, let `offset` be a value of type `size_t` equal to `operator()(ls...)`.

23.7.3.7.7.3 `layout_left` specialization of `submdspan_mapping` [mdspan.sub.map.left]

```
template<class Extents>
template<class... SliceSpecifiers>
constexpr auto layout_left::mapping<Extents>::submdspan-mapping-impl(
      SliceSpecifiers... slices) const -> see below;
```

1 *Returns*:

(1.1) — `submdspan_mapping_result{*this, 0}`, if `Extents::rank() == 0` is `true`;

(1.2) — otherwise, `submdspan_mapping_result{layout_left::mapping(sub_ext), offset}`, if `SubExtents::rank() == 0` is `true`;

(1.3) — otherwise, `submdspan_mapping_result{layout_left::mapping(sub_ext), offset}`, if

(1.3.1) — for each k in the range $[0,$ `SubExtents::rank() - 1`$)$, `SliceSpecifiers...[`k`]` denotes `full_extent_t`; and

(1.3.2) — for k equal to `SubExtents::rank() - 1`, `SliceSpecifiers...[`k`]` is a unit-stride slice type;

[*Note 1*: If the above conditions are true, all `SliceSpecifiers...[`k`]` with k larger than `SubExtents::rank() - 1` are convertible to `index_type`. — *end note*]

(1.4) — otherwise,

```
submdspan_mapping_result{layout_left_padded<S_static>::mapping(sub_ext, stride(u + 1)),
                         offset}
```

if for a value u for which $u+1$ is the smallest value p larger than zero for which `SliceSpecifiers...[`p`]` is a unit-stride slice type, the following conditions are met:

(1.4.1) — `SliceSpecifiers...[0]` is a unit-stride slice type; and

(1.4.2) — for each k in the range $[u$ `+ 1`$, u$ `+ SubExtents::rank() - 1`$)$, `SliceSpecifiers...[`k`]` denotes `full_extent_t`; and

(1.4.3) — for k equal to u + SubExtents::rank() - 1, SliceSpecifiers...[k] is a unit-stride slice type;

and where S_static is:

(1.4.4) — dynamic_extent, if static_extent(k) is dynamic_extent for any k in the range $[0, u + 1)$,

(1.4.5) — otherwise, the product of all values static_extent(k) for k in the range $[0, u + 1)$;

(1.5) — otherwise,

```
submdspan_mapping_result{layout_stride::mapping(sub_ext, sub_strides), offset}
```

23.7.3.7.7.4 layout_right specialization of submdspan_mapping [mdspan.sub.map.right]

```
template<class Extents>
template<class... SliceSpecifiers>
constexpr auto layout_right::mapping<Extents>::submdspan-mapping-impl(
      SliceSpecifiers... slices) const -> see below;
```

1 *Returns*:

(1.1) — submdspan_mapping_result{*this, 0}, if Extents::rank() == 0 is true;

(1.2) — otherwise, submdspan_mapping_result{layout_right::mapping(sub_ext), offset}, if SubExtents::rank() == 0 is true;

(1.3) — otherwise, submdspan_mapping_result{layout_right::mapping(sub_ext), offset}, if

(1.3.1) — for each k in the range [*rank_* - SubExtents::rank() + 1, *rank_*), SliceSpecifiers...[k] denotes full_extent_t; and

(1.3.2) — for k equal to *rank_* - SubExtents::rank(), SliceSpecifiers...[k] is a unit-stride slice type;

[*Note 1*: If the above conditions are true, all SliceSpecifiers...[k] with $k <$ *rank_* - SubExtents::rank() are convertible to index_type. — *end note*]

(1.4) — otherwise,

```
submdspan_mapping_result{layout_right_padded<S_static>::mapping(sub_ext,
                                 stride(rank_ - u - 2)), offset}
```

if for a value u for which *rank_* $- u - 2$ is the largest value p smaller than *rank_* - 1 for which SliceSpecifiers...[p] is a unit-stride slice type, the following conditions are met:

(1.4.1) — for k equal to *rank_* - 1, SliceSpecifiers...[k] is a unit-stride slice type; and

(1.4.2) — for each k in the range [*rank_* - SubExtents::rank() - u + 1, *rank_* - u - 1), SliceSpecifiers...[p] denotes full_extent_t; and

(1.4.3) — for k equal to *rank_* - SubExtents::rank() - u, SliceSpecifiers...[k] is a unit-stride slice type;

and where S_static is:

(1.4.4) — dynamic_extent, if static_extent(k) is dynamic_extent for any k in the range [*rank_* - u - 1, *rank_*),

(1.4.5) — otherwise, the product of all values static_extent(k) for k in the range [*rank_* - u - 1, *rank_*);

(1.5) — otherwise,

```
submdspan_mapping_result{layout_stride::mapping(sub_ext, sub_strides), offset}
```

23.7.3.7.7.5 layout_stride specialization of submdspan_mapping [mdspan.sub.map.stride]

```
template<class Extents>
template<class... SliceSpecifiers>
constexpr auto layout_stride::mapping<Extents>::submdspan-mapping-impl(
      SliceSpecifiers... slices) const -> see below;
```

1 *Returns*:

(1.1) — submdspan_mapping_result{*this, 0}, if Extents::rank() == 0 is true;

(1.2) — otherwise,

```
submdspan_mapping_result{layout_stride::mapping(sub_ext, sub_strides), offset}
```

23.7.3.7.7.6 `layout_left_padded` specialization of `submdspan_mapping`[mdspan.sub.map.leftpad]

```
template<class Extents>
template<class... SliceSpecifiers>
constexpr auto layout_left_padded::mapping<Extents>::submdspan-mapping-impl(
    SliceSpecifiers... slices) const -> see below;
```

1 *Returns*:

(1.1) — `submdspan_mapping_result{*this, 0}`, if `Extents::rank() == 0` is `true`;

(1.2) — otherwise, `submdspan_mapping_result{layout_left::mapping(sub_ext), offset}`, if *`rank_`* `== 1` is `true` or `SubExtents::rank() == 0` is `true`;

(1.3) — otherwise, `submdspan_mapping_result{layout_left::mapping(sub_ext), offset}`, if

(1.3.1) — `SubExtents::rank() == 1` is `true` and

(1.3.2) — `SliceSpecifiers...[0]` is a unit-stride slice type;

(1.4) — otherwise,

```
submdspan_mapping_result{layout_left_padded<S_static>::mapping(sub_ext, stride(u + 1)),
                         offset}
```

if for a value u for which u `+ 1` is the smallest value p larger than zero for which `SliceSpecifiers...[`p`]` is a unit-stride slice type, the following conditions are met:

(1.4.1) — `SliceSpecifiers...[0]` is a unit-stride slice type; and

(1.4.2) — for each k in the range $[u$ `+ 1`$, u$ `+ SubExtents::rank() - 1`$)$, `SliceSpecifiers...[`k`]` denotes `full_extent_t`; and

(1.4.3) — for k equal to u `+ SubExtents::rank() - 1`, `SliceSpecifiers...[`k`]` is a unit-stride slice type;

where `S_static` is:

(1.4.4) — `dynamic_extent`, if *`static-padding-stride`* is `dynamic_extent` or `static_extent(`k`)` is `dynamic_extent` for any k in the range $[1, u$ `+ 1`$)$,

(1.4.5) — otherwise, the product of *`static-padding-stride`* and all values `static_extent(`k`)` for k in the range $[1, u$ `+ 1`$)$;

(1.5) — otherwise,

```
submdspan_mapping_result{layout_stride::mapping(sub_ext, sub_strides), offset}
```

23.7.3.7.7.7 `layout_right_padded` specialization of `submdspan_mapping` [mdspan.sub.map.rightpad]

```
template<class Extents>
template<class... SliceSpecifiers>
constexpr auto layout_right_padded::mapping<Extents>::submdspan-mapping-impl(
    SliceSpecifiers... slices) const -> see below;
```

1 *Returns*:

(1.1) — `submdspan_mapping_result{*this, 0}`, if *`rank_`* `== 0` is `true`;

(1.2) — otherwise, `submdspan_mapping_result{layout_right::mapping(sub_ext), offset}`, if *`rank_`* `== 1` is `true` or `SubExtents::rank() == 0` is `true`;

(1.3) — otherwise, `submdspan_mapping_result{layout_right::mapping(sub_ext), offset}`, if

(1.3.1) — `SubExtents::rank() == 1` is `true` and

(1.3.2) — for k equal to *`rank_`* `- 1`, `SliceSpecifiers...[`k`]` is a unit-stride slice type;

(1.4) — otherwise,

```
submdspan_mapping_result{layout_right_padded<S_static>::mapping(sub_ext,
                                stride(rank_ - u - 2)), offset}
```

if for a value u for which *rank_* - u - 2 is the largest value p smaller than *rank_* - 1 for which SliceSpecifiers...[p] is a unit-stride slice type, the following conditions are met:

(1.4.1) — for k equal to *rank_* - 1, SliceSpecifiers...[k] is a unit-stride slice type; and

(1.4.2) — for each k in the range [*rank_* - SubExtents::rank() - u + 1, *rank_* - u - 1), SliceSpecifiers...[k] denotes full_extent_t; and

(1.4.3) — for k equal to *rank_* - SubExtents::rank() - u, SliceSpecifiers...[k] is a unit-stride slice type;

and where S_static is:

(1.4.4) — dynamic_extent if *static-padding-stride* is dynamic_extent or for any k in the range [*rank_* - u - 1, *rank_* - 1) static_extent(k) is dynamic_extent,

(1.4.5) — otherwise, the product of *static-padding-stride* and all values static_extent(k) with k in the range [*rank_* - u - 1, *rank_* - 1);

(1.5) — otherwise,

```
submdspan_mapping_result{layout_stride::mapping(sub_ext, sub_strides), offset}
```

23.7.3.7.8 submdspan function template [mdspan.sub.sub]

```
template<class ElementType, class Extents, class LayoutPolicy,
         class AccessorPolicy, class... SliceSpecifiers>
  constexpr auto submdspan(
    const mdspan<ElementType, Extents, LayoutPolicy, AccessorPolicy>& src,
    SliceSpecifiers... raw_slices) -> see below;
```

1 Let index_type be typename Extents::index_type.

2 Let slices be the pack introduced by the following declaration:

```
auto [...slices] = canonical_slices(src.extents(), raw_slices...);
```

3 Let sub_map_offset be the result of submdspan_mapping(src.mapping(), slices...).

[*Note 1*: This invocation of submdspan_mapping selects a function call via overload resolution on a candidate set that includes the lookup set found by argument-dependent lookup (6.5.4). — *end note*]

4 *Constraints*:

(4.1) — sizeof...(slices) equals Extents::rank(), and

(4.2) — LayoutPolicy::mapping<Extents> models *sliceable-mapping*.

5 *Mandates*: For each rank index k of src:

(5.1) — SliceSpecifiers...[k] is a submdspan slice type for index_type, and

(5.2) — decltype(slices...[k]) is a valid submdspan slice type for the k^{th} extent of Extents.

6 *Preconditions*: For each rank index k of src.extents(), slices...[k] is a valid submdspan slice for the k^{th} extent of src.extents().

7 *Effects*: Equivalent to:

```
auto sub_map_result = submdspan_mapping(src.mapping(), slices...);
return mdspan(src.accessor().offset(src.data_handle(), sub_map_result.offset),
              sub_map_result.mapping,
              typename AccessorPolicy::offset_policy(src.accessor()));
```

8 [*Example 1*: Given a rank-3 mdspan grid3d representing a three-dimensional grid of regularly spaced points in a rectangular prism, the function zero_surface sets all elements on the surface of the 3-dimensional shape to zero. It does so by reusing a function zero_2d that takes a rank-2 mdspan.

```
// zero out all elements in an mdspan
template<class T, class E, class L, class A>
void zero_2d(mdspan<T, E, L, A> a) {
  static_assert(a.rank() == 2);
  for (int i = 0; i < a.extent(0); i++)
    for (int j = 0; j < a.extent(1); j++)
      a[i, j] = 0;
}
```

```
// zero out just the surface
template<class T, class E, class L, class A>
void zero_surface(mdspan<T, E, L, A> grid3d) {
  static_assert(grid3d.rank() == 3);
  zero_2d(submdspan(grid3d, 0, full_extent, full_extent));
  zero_2d(submdspan(grid3d, full_extent, 0, full_extent));
  zero_2d(submdspan(grid3d, full_extent, full_extent, 0));
  zero_2d(submdspan(grid3d, grid3d.extent(0) - 1, full_extent, full_extent));
  zero_2d(submdspan(grid3d, full_extent, grid3d.extent(1) - 1, full_extent));
  zero_2d(submdspan(grid3d, full_extent, full_extent, grid3d.extent(2) - 1));
}
```

— *end example*]

24 Iterators library [iterators]

24.1 General [iterators.general]

1 This Clause describes components that C++ programs may use to perform iterations over containers (Clause 23), streams (31.7), stream buffers (31.6), and other ranges (Clause 25).

2 The following subclauses describe iterator requirements, and components for iterator primitives, predefined iterators, and stream iterators, as summarized in Table 76.

Table 76 — Iterators library summary [tab:iterators.summary]

	Subclause	Header
24.3	Iterator requirements	`<iterator>`
24.4	Iterator primitives	
24.5	Iterator adaptors	
24.6	Stream iterators	
24.7	Range access	

24.2 Header `<iterator>` synopsis [iterator.synopsis]

```
#include <compare>              // see 17.12.1
#include <concepts>             // see 18.3
#include <initializer_list>     // see 17.11.2

template<class C> constexpr auto
  size(const C& c) noexcept(noexcept(c.size())) -> decltype(c.size());             // freestanding
template<class T, size_t N> constexpr size_t
  size(const T (&array)[N]) noexcept;                                              // freestanding
```

```
  template<class C> constexpr auto
    ssize(const C& c) noexcept(noexcept(c.size()))
      -> common_type_t<ptrdiff_t, make_signed_t<decltype(c.size())>>;          // freestanding
  template<class T, ptrdiff_t N> constexpr ptrdiff_t
    ssize(const T (&array)[N]) noexcept;                                       // freestanding

  template<class C> constexpr auto
    empty(const C& c) noexcept(noexcept(c.empty())) -> decltype(c.empty());    // freestanding
  template<class T, size_t N> constexpr bool
    empty(const T (&array)[N]) noexcept;                                       // freestanding

  template<class C> constexpr auto
    data(C& c) noexcept(noexcept(c.data())) -> decltype(c.data());             // freestanding
  template<class C> constexpr auto
    data(const C& c) noexcept(noexcept(c.data())) -> decltype(c.data());       // freestanding
  template<class T, size_t N> constexpr T* data(T (&array)[N]) noexcept;       // freestanding
}
```

24.3 Iterator requirements [iterator.requirements]

24.3.1 General [iterator.requirements.general]

1 Iterators are a generalization of pointers that allow a C++ program to work with different data structures (for example, containers and ranges) in a uniform manner. To be able to construct template algorithms that work correctly and efficiently on different types of data structures, the library formalizes not just the interfaces but also the semantics and complexity assumptions of iterators. An input iterator `i` supports the expression `*i`, resulting in a value of some object type `T`, called the *value type* of the iterator. An output iterator `i` has a non-empty set of types that are *writable* to the iterator; for each such type `T`, the expression `*i = o` is valid where `o` is a value of type `T`. For every iterator type `X`, there is a corresponding signed integer-like type (24.3.4.4) called the *difference type* of the iterator.

2 Since iterators are an abstraction of pointers, their semantics are a generalization of most of the semantics of pointers in C++. This ensures that every function template that takes iterators works as well with regular pointers. This document defines six categories of iterators, according to the operations defined on them: *input iterators*, *output iterators*, *forward iterators*, *bidirectional iterators*, *random access iterators*, and *contiguous iterators*, as shown in Table 77.

Table 77 — Relations among iterator categories [tab:iterators.relations]

Contiguous	**→ Random Access**	**→ Bidirectional**	**→ Forward**	**→ Input** **→ Output**

3 The six categories of iterators correspond to the iterator concepts

(3.1) — `input_iterator` (24.3.4.9),

(3.2) — `output_iterator` (24.3.4.10),

(3.3) — `forward_iterator` (24.3.4.11),

(3.4) — `bidirectional_iterator` (24.3.4.12),

(3.5) — `random_access_iterator` (24.3.4.13), and

(3.6) — `contiguous_iterator` (24.3.4.14),

respectively. The generic term *iterator* refers to any type that models the `input_or_output_iterator` concept (24.3.4.6).

4 Forward iterators meet all the requirements of input iterators and can be used whenever an input iterator is specified; Bidirectional iterators also meet all the requirements of forward iterators and can be used whenever a forward iterator is specified; Random access iterators also meet all the requirements of bidirectional iterators and can be used whenever a bidirectional iterator is specified; Contiguous iterators also meet all the requirements of random access iterators and can be used whenever a random access iterator is specified.

5 Iterators that further meet the requirements of output iterators are called *mutable iterators*. Nonmutable iterators are referred to as *constant iterators*.

6 In addition to the requirements in this subclause, the nested *typedef-name*s specified in 24.3.2.3 shall be provided for the iterator type.

[*Note 1*: Either the iterator type must provide the *typedef-name*s directly (in which case `iterator_traits` pick them up automatically), or an `iterator_traits` specialization must provide them. — *end note*]

7 Just as a regular pointer to an array guarantees that there is a pointer value pointing past the last element of the array, so for any iterator type there is an iterator value that points past the last element of a corresponding sequence. Such a value is called a *past-the-end value*. Values of an iterator `i` for which the expression `*i` is defined are called *dereferenceable*. The library never assumes that past-the-end values are dereferenceable. Iterators can also have singular values that are not associated with any sequence. Results of most expressions are undefined for singular values; the only exceptions are destroying an iterator that holds a singular value, the assignment of a non-singular value to an iterator that holds a singular value, and, for iterators that meet the *Cpp17DefaultConstructible* requirements, using a value-initialized iterator as the source of a copy or move operation.

[*Note 2*: This guarantee is not offered for default-initialization, although the distinction only matters for types with trivial default constructors such as pointers or aggregates holding pointers. — *end note*]

In these cases the singular value is overwritten the same way as any other value. Dereferenceable values are always non-singular.

8 Most of the library's algorithmic templates that operate on data structures have interfaces that use ranges. A *range* is an iterator and a *sentinel* that designate the beginning and end of the computation, or an iterator and a count that designate the beginning and the number of elements to which the computation is to be applied.[178]

9 An iterator and a sentinel denoting a range are comparable. A range $[$`i`, `s`$)$ is empty if `i == s`; otherwise, $[$`i`, `s`$)$ refers to the elements in the data structure starting with the element pointed to by `i` and up to but not including the element, if any, pointed to by the first iterator `j` such that `j == s`.

10 A sentinel `s` is called *reachable from* an iterator `i` if and only if there is a finite sequence of applications of the expression `++i` that makes `i == s`. If `s` is reachable from `i`, $[$`i`, `s`$)$ denotes a *valid range*.

11 A *counted range* `i` + $[$`0`, `n`$)$ is empty if `n == 0`; otherwise, `i` + $[$`0`, `n`$)$ refers to the `n` elements in the data structure starting with the element pointed to by `i` and up to but not including the element, if any, pointed to by the result of `n` applications of `++i`. A counted range `i` + $[$`0`, `n`$)$ is *valid* if and only if `n == 0`; or `n` is positive, `i` is dereferenceable, and `++i` + $[$`0`, `--n`$)$ is valid.

12 The result of the application of library functions to invalid ranges is undefined.

13 For an iterator `i` of a type that models `contiguous_iterator` (24.3.4.14), library functions are permitted to replace $[$`i`, `s`$)$ with $[$`to_address(i)`, `to_address(i + ranges::distance(i, s))`$)$, and to replace `i` + $[$`0`, `n`$)$ with $[$`to_address(i)`, `to_address(i + n)`$)$.

[*Note 3*: This means a program cannot rely on any side effects of dereferencing a contiguous iterator `i`, because library functions might operate on pointers obtained by `to_address(i)` instead of operating on `i`. Similarly, a program cannot rely on any side effects of individual increments on a contiguous iterator `i`, because library functions might advance `i` only once. — *end note*]

14 All the categories of iterators require only those functions that are realizable for a given category in constant time (amortized). Therefore, requirement tables and concept definitions for the iterators do not specify complexity.

15 Destruction of an iterator may invalidate pointers and references previously obtained from that iterator if its type does not meet the *Cpp17ForwardIterator* requirements and does not model `forward_iterator`.

16 An *invalid iterator* is an iterator that may be singular.[179]

17 Iterators meet the *constexpr iterator* requirements if all operations provided to meet iterator category requirements are constexpr functions.

[*Note 4*: For example, the types "pointer to `int`" and `reverse_iterator<int*>` meet the constexpr iterator requirements. — *end note*]

178) The sentinel denoting the end of a range can have the same type as the iterator denoting the beginning of the range, or a different type.

179) This definition applies to pointers, since pointers are iterators. The effect of dereferencing an iterator that has been invalidated is undefined.

24.3.2 Associated types [iterator.assoc.types]

24.3.2.1 Incrementable traits [incrementable.traits]

1 To implement algorithms only in terms of incrementable types, it is often necessary to determine the difference type that corresponds to a particular incrementable type. Accordingly, it is required that if `WI` is the name of a type that models the `weakly_incrementable` concept (24.3.4.4), the type

```
iter_difference_t<WI>
```

be defined as the incrementable type's difference type.

```
namespace std {
  template<class> struct incrementable_traits { };

  template<class T>
    requires is_object_v<T>
  struct incrementable_traits<T*> {
    using difference_type = ptrdiff_t;
  };

  template<class I>
  struct incrementable_traits<const I>
    : incrementable_traits<I> { };

  template<class T>
    requires requires { typename T::difference_type; }
  struct incrementable_traits<T> {
    using difference_type = T::difference_type;
  };

  template<class T>
    requires (!requires { typename T::difference_type; } &&
              requires(const T& a, const T& b) { { a - b } -> integral; })
  struct incrementable_traits<T> {
    using difference_type = make_signed_t<decltype(declval<T>() - declval<T>())>;
  };

  template<class T>
    using iter_difference_t = see below;
}
```

2 Let R_{I} be `remove_cvref_t<I>`. The type `iter_difference_t<I>` denotes

(2.1) — `incrementable_traits<`R_{I}`>::difference_type` if `iterator_traits<`R_{I}`>` names a specialization generated from the primary template, and

(2.2) — `iterator_traits<`R_{I}`>::difference_type` otherwise.

3 Users may specialize `incrementable_traits` on program-defined types.

24.3.2.2 Indirectly readable traits [readable.traits]

1 To implement algorithms only in terms of indirectly readable types, it is often necessary to determine the value type that corresponds to a particular indirectly readable type. Accordingly, it is required that if `R` is the name of a type that models the `indirectly_readable` concept (24.3.4.2), the type

```
iter_value_t<R>
```

be defined as the indirectly readable type's value type.

```
template<class> struct cond-value-type { };      // exposition only
template<class T>
  requires is_object_v<T>
struct cond-value-type<T> {
  using value_type = remove_cv_t<T>;
};

template<class T>
  concept has-member-value-type = requires { typename T::value_type; };          // exposition only
```

```
template<class T>
  concept has-member-element-type = requires { typename T::element_type; };      // exposition only

template<class> struct indirectly_readable_traits { };

template<class T>
struct indirectly_readable_traits<T*>
  : cond-value-type<T> { };

template<class I>
  requires is_array_v<I>
struct indirectly_readable_traits<I> {
  using value_type = remove_cv_t<remove_extent_t<I>>;
};

template<class I>
struct indirectly_readable_traits<const I>
  : indirectly_readable_traits<I> { };

template<has-member-value-type T>
struct indirectly_readable_traits<T>
  : cond-value-type<typename T::value_type> { };

template<has-member-element-type T>
struct indirectly_readable_traits<T>
  : cond-value-type<typename T::element_type> { };

template<has-member-value-type T>
  requires has-member-element-type<T>
struct indirectly_readable_traits<T> { };

template<has-member-value-type T>
  requires has-member-element-type<T> &&
           same_as<remove_cv_t<typename T::element_type>, remove_cv_t<typename T::value_type>>
struct indirectly_readable_traits<T>
  : cond-value-type<typename T::value_type> { };

template<class T> using iter_value_t = see below;
```

2 Let $R_{\mathtt{I}}$ be `remove_cvref_t<I>`. The type `iter_value_t<I>` denotes

(2.1) — `indirectly_readable_traits<`$R_{\mathtt{I}}$`>::value_type` if `iterator_traits<`$R_{\mathtt{I}}$`>` names a specialization generated from the primary template, and

(2.2) — `iterator_traits<`$R_{\mathtt{I}}$`>::value_type` otherwise.

3 Class template `indirectly_readable_traits` may be specialized on program-defined types.

4 [*Note 1*: Some legacy output iterators declare a nested type named `value_type` that is an alias for `void`. These types are not `indirectly_readable` and have no associated value types. — *end note*]

5 [*Note 2*: Smart pointers like `shared_ptr<int>` are `indirectly_readable` and have an associated value type, but a smart pointer like `shared_ptr<void>` is not `indirectly_readable` and has no associated value type. — *end note*]

24.3.2.3 Iterator traits [iterator.traits]

1 To implement algorithms only in terms of iterators, it is sometimes necessary to determine the iterator category that corresponds to a particular iterator type. Accordingly, it is required that if `I` is the type of an iterator, the type

```
iterator_traits<I>::iterator_category
```

be declared as the iterator's iterator category. In addition, the types

```
iterator_traits<I>::pointer
iterator_traits<I>::reference
```

shall be declared as the iterator's pointer and reference types; that is, for an iterator object `a` of class type, the same type as `decltype(a.operator->())` and `decltype(*a)`, respectively. The type `iterator_-`

`traits<I>::pointer` shall be `void` for an iterator of class type `I` that does not support `operator->`. Additionally, in the case of an output iterator, the types

```
iterator_traits<I>::value_type
iterator_traits<I>::difference_type
iterator_traits<I>::reference
```

may be declared as `void`.

2 The definitions in this subclause make use of the following exposition-only concepts:

```
template<class I>
concept cpp17-iterator =
  requires(I i) {
    {   *i } -> can-reference;
    {  ++i } -> same_as<I&>;
    { *i++ } -> can-reference;
  } && copyable<I>;

template<class I>
concept cpp17-input-iterator =
  cpp17-iterator<I> && equality_comparable<I> && requires(I i) {
    typename incrementable_traits<I>::difference_type;
    typename indirectly_readable_traits<I>::value_type;
    typename common_reference_t<iter_reference_t<I>&&,
                                typename indirectly_readable_traits<I>::value_type&>;
    typename common_reference_t<decltype(*i++)&&,
                                typename indirectly_readable_traits<I>::value_type&>;
    requires signed_integral<typename incrementable_traits<I>::difference_type>;
  };

template<class I>
concept cpp17-forward-iterator =
  cpp17-input-iterator<I> && constructible_from<I> &&
  is_reference_v<iter_reference_t<I>> &&
  same_as<remove_cvref_t<iter_reference_t<I>>,
          typename indirectly_readable_traits<I>::value_type> &&
  requires(I i) {
    {  i++ } -> convertible_to<const I&>;
    { *i++ } -> same_as<iter_reference_t<I>>;
  };

template<class I>
concept cpp17-bidirectional-iterator =
  cpp17-forward-iterator<I> && requires(I i) {
    {  --i } -> same_as<I&>;
    {  i-- } -> convertible_to<const I&>;
    { *i-- } -> same_as<iter_reference_t<I>>;
  };

template<class I>
concept cpp17-random-access-iterator =
  cpp17-bidirectional-iterator<I> && totally_ordered<I> &&
  requires(I i, typename incrementable_traits<I>::difference_type n) {
    { i += n } -> same_as<I&>;
    { i -= n } -> same_as<I&>;
    { i +  n } -> same_as<I>;
    { n +  i } -> same_as<I>;
    { i -  n } -> same_as<I>;
    { i -  i } -> same_as<decltype(n)>;
    {  i[n]  } -> convertible_to<iter_reference_t<I>>;
  };
```

3 The members of a specialization `iterator_traits<I>` generated from the `iterator_traits` primary template are computed as follows:

(3.1) — If `I` has valid (13.10.3) member types `difference_type`, `value_type`, `reference`, and `iterator_category`, then `iterator_traits<I>` has the following publicly accessible members:

```
using iterator_category = I::iterator_category;
using value_type        = I::value_type;
using difference_type   = I::difference_type;
using pointer           = see below;
using reference         = I::reference;
```

If the *qualified-id* `I::pointer` is valid and denotes a type, then `iterator_traits<I>::pointer` names that type; otherwise, it names `void`.

(3.2) — Otherwise, if `I` satisfies the exposition-only concept *cpp17-input-iterator*, `iterator_traits<I>` has the following publicly accessible members:

```
using iterator_category = see below;
using value_type        = indirectly_readable_traits<I>::value_type;
using difference_type   = incrementable_traits<I>::difference_type;
using pointer           = see below;
using reference         = see below;
```

(3.2.1) — If the *qualified-id* `I::pointer` is valid and denotes a type, `pointer` names that type. Otherwise, if `decltype(declval<I&>().operator->())` is well-formed, then `pointer` names that type. Otherwise, `pointer` names `void`.

(3.2.2) — If the *qualified-id* `I::reference` is valid and denotes a type, `reference` names that type. Otherwise, `reference` names `iter_reference_t<I>`.

(3.2.3) — If the *qualified-id* `I::iterator_category` is valid and denotes a type, `iterator_category` names that type. Otherwise, `iterator_category` names:

(3.2.3.1) — `random_access_iterator_tag` if `I` satisfies *cpp17-random-access-iterator*, or otherwise

(3.2.3.2) — `bidirectional_iterator_tag` if `I` satisfies *cpp17-bidirectional-iterator*, or otherwise

(3.2.3.3) — `forward_iterator_tag` if `I` satisfies *cpp17-forward-iterator*, or otherwise

(3.2.3.4) — `input_iterator_tag`.

(3.3) — Otherwise, if `I` satisfies the exposition-only concept *cpp17-iterator*, then `iterator_traits<I>` has the following publicly accessible members:

```
using iterator_category = output_iterator_tag;
using value_type        = void;
using difference_type   = see below;
using pointer           = void;
using reference         = void;
```

If the *qualified-id* `incrementable_traits<I>::difference_type` is valid and denotes a type, then `difference_type` names that type; otherwise, it names `void`.

(3.4) — Otherwise, `iterator_traits<I>` has no members by any of the above names.

4 Explicit or partial specializations of `iterator_traits` may have a member type `iterator_concept` that is used to indicate conformance to the iterator concepts (24.3.4).

[*Example 1*: To indicate conformance to the `input_iterator` concept but a lack of conformance to the *Cpp17InputIterator* requirements (24.3.5.3), an `iterator_traits` specialization might have `iterator_concept` denote `input_iterator_tag` but not declare `iterator_category`. — *end example*]

5 `iterator_traits` is specialized for pointers as

```
namespace std {
  template<class T>
    requires is_object_v<T>
  struct iterator_traits<T*> {
    using iterator_concept  = contiguous_iterator_tag;
    using iterator_category = random_access_iterator_tag;
    using value_type        = remove_cv_t<T>;
    using difference_type   = ptrdiff_t;
    using pointer           = T*;
    using reference         = T&;
```

```
  };
}
```

6 [*Example 2*: To implement a generic `reverse` function, a C++ program can do the following:

```
template<class BI>
void reverse(BI first, BI last) {
  typename iterator_traits<BI>::difference_type n = distance(first, last);
  --n;
  while (n > 0) {
    typename iterator_traits<BI>::value_type tmp = *first;
    *first++ = *--last;
    *last = tmp;
    n -= 2;
  }
}
```

— *end example*]

24.3.3 Customization point objects [iterator.cust]

24.3.3.1 `ranges::iter_move` [iterator.cust.move]

1 The name `ranges::iter_move` denotes a customization point object (16.3.3.3.5). The expression `ranges::iter_move(E)` for a subexpression `E` is expression-equivalent to:

(1.1) — `iter_move(E)`, if `E` has class or enumeration type and `iter_move(E)` is a well-formed expression when treated as an unevaluated operand, where the meaning of `iter_move` is established as-if by performing argument-dependent lookup only (6.5.4).

(1.2) — Otherwise, if the expression `*E` is well-formed:

(1.2.1) — if `*E` is an lvalue, `std::move(*E)`;

(1.2.2) — otherwise, `*E`.

(1.3) — Otherwise, `ranges::iter_move(E)` is ill-formed.

[*Note 1*: This case can result in substitution failure when `ranges::iter_move(E)` appears in the immediate context of a template instantiation. — *end note*]

2 If `ranges::iter_move(E)` is not equal to `*E`, the program is ill-formed, no diagnostic required.

24.3.3.2 `ranges::iter_swap` [iterator.cust.swap]

1 The name `ranges::iter_swap` denotes a customization point object (16.3.3.3.5) that exchanges the values (18.4.9) denoted by its arguments.

2 Let *`iter-exchange-move`* be the exposition-only function template:

```
template<class X, class Y>
  constexpr iter_value_t<X> iter-exchange-move(X&& x, Y&& y)
    noexcept(noexcept(iter_value_t<X>(iter_move(x))) &&
             noexcept(*x = iter_move(y)));
```

3 *Effects*: Equivalent to:

```
iter_value_t<X> old_value(iter_move(x));
*x = iter_move(y);
return old_value;
```

4 The expression `ranges::iter_swap(E1, E2)` for subexpressions `E1` and `E2` is expression-equivalent to:

(4.1) — `(void)iter_swap(E1, E2)`, if either `E1` or `E2` has class or enumeration type and `iter_swap(E1, E2)` is a well-formed expression with overload resolution performed in a context that includes the declaration

```
template<class I1, class I2>
  void iter_swap(I1, I2) = delete;
```

and does not include a declaration of `ranges::iter_swap`. If the function selected by overload resolution does not exchange the values denoted by `E1` and `E2`, the program is ill-formed, no diagnostic required.

[*Note 1*: This precludes calling unconstrained `std::iter_swap`. When the deleted overload is viable, program-defined overloads need to be more specialized (13.7.7.3) to be selected. — *end note*]

(4.2) — Otherwise, if the types of `E1` and `E2` each model `indirectly_readable`, and if the reference types of `E1` and `E2` model `swappable_with` (18.4.9), then `ranges::swap(*E1, *E2)`.

(4.3) — Otherwise, if the types `T1` and `T2` of `E1` and `E2` model `indirectly_movable_storable<T1, T2>` and `indirectly_movable_storable<T2, T1>`, then `(void)(*E1 = `*`iter-exchange-move`*`(E2, E1))`, except that `E1` is evaluated only once.

(4.4) — Otherwise, `ranges::iter_swap(E1, E2)` is ill-formed.

[*Note 2*: This case can result in substitution failure when `ranges::iter_swap(E1, E2)` appears in the immediate context of a template instantiation. — *end note*]

24.3.4 Iterator concepts [iterator.concepts]

24.3.4.1 General [iterator.concepts.general]

1 For a type `I`, let *`ITER_TRAITS`*`(I)` denote the type `I` if `iterator_traits<I>` names a specialization generated from the primary template. Otherwise, *`ITER_TRAITS`*`(I)` denotes `iterator_traits<I>`.

(1.1) — If the *qualified-id* *`ITER_TRAITS`*`(I)::iterator_concept` is valid and names a type, then *`ITER_CONCEPT`*`(I)` denotes that type.

(1.2) — Otherwise, if the *qualified-id* *`ITER_TRAITS`*`(I)::iterator_category` is valid and names a type, then *`ITER_CONCEPT`*`(I)` denotes that type.

(1.3) — Otherwise, if `iterator_traits<I>` names a specialization generated from the primary template, then *`ITER_CONCEPT`*`(I)` denotes `random_access_iterator_tag`.

(1.4) — Otherwise, *`ITER_CONCEPT`*`(I)` does not denote a type.

2 [*Note 1*: *`ITER_TRAITS`* enables independent syntactic determination of an iterator's category and concept. — *end note*]

[*Example 1*:

```
struct I {
  using value_type = int;
  using difference_type = int;

  int operator*() const;
  I& operator++();
  I operator++(int);
  I& operator--();
  I operator--(int);

  bool operator==(I) const;
};
```

`iterator_traits<I>::iterator_category` denotes `input_iterator_tag`, and *`ITER_CONCEPT`*`(I)` denotes `random_access_iterator_tag`. — *end example*]

24.3.4.2 Concept `indirectly_readable` [iterator.concept.readable]

1 Types that are indirectly readable by applying `operator*` model the `indirectly_readable` concept, including pointers, smart pointers, and iterators.

```
template<class In>
  concept indirectly-readable-impl =                    // exposition only
    requires(const In in) {
      typename iter_value_t<In>;
      typename iter_reference_t<In>;
      typename iter_rvalue_reference_t<In>;
      { *in } -> same_as<iter_reference_t<In>>;
      { ranges::iter_move(in) } -> same_as<iter_rvalue_reference_t<In>>;
    } &&
    common_reference_with<iter_reference_t<In>&&, iter_value_t<In>&> &&
    common_reference_with<iter_reference_t<In>&&, iter_rvalue_reference_t<In>&&> &&
    common_reference_with<iter_rvalue_reference_t<In>&&, const iter_value_t<In>&>;

template<class In>
  concept indirectly_readable =
    indirectly-readable-impl<remove_cvref_t<In>>;
```

2 Given a value `i` of type `I`, `I` models `indirectly_readable` only if the expression `*i` is equality-preserving.

24.3.4.3 Concept `indirectly_writable` [iterator.concept.writable]

1 The `indirectly_writable` concept specifies the requirements for writing a value into an iterator's referenced object.

```
template<class Out, class T>
  concept indirectly_writable =
    requires(Out&& o, T&& t) {
      *o = std::forward<T>(t);                          // not required to be equality-preserving
      *std::forward<Out>(o) = std::forward<T>(t);       // not required to be equality-preserving
      const_cast<const iter_reference_t<Out>&&>(*o) =
        std::forward<T>(t);                             // not required to be equality-preserving
      const_cast<const iter_reference_t<Out>&&>(*std::forward<Out>(o)) =
        std::forward<T>(t);                             // not required to be equality-preserving
    };
```

2 Let `E` be an expression such that `decltype((E))` is `T`, and let `o` be a dereferenceable object of type `Out`. `Out` and `T` model `indirectly_writable<Out, T>` only if:

(2.1) — If `Out` and `T` model `indirectly_readable<Out> && same_as<iter_value_t<Out>, decay_t<T>>`, then `*o` after any above assignment is equal to the value of `E` before the assignment.

3 After evaluating any above assignment expression, `o` is not required to be dereferenceable.

4 If `E` is an xvalue (7.2.1), the resulting state of the object it denotes is valid but unspecified (16.4.6.17).

5 [*Note 1*: The only valid use of an `operator*` is on the left side of the assignment statement. Assignment through the same value of the indirectly writable type happens only once. — *end note*]

6 [*Note 2*: `indirectly_writable` has the awkward `const_cast` expressions to reject iterators with prvalue non-proxy reference types that permit rvalue assignment but do not also permit `const` rvalue assignment. Consequently, an iterator type `I` that returns `std::string` by value does not model `indirectly_writable<I, std::string>`. — *end note*]

24.3.4.4 Concept `weakly_incrementable` [iterator.concept.winc]

1 The `weakly_incrementable` concept specifies the requirements on types that can be incremented with the pre- and post-increment operators. The increment operations are not required to be equality-preserving, nor is the type required to be `equality_comparable`.

```
template<class T>
  constexpr bool is-integer-like = see below;           // exposition only

template<class T>
  constexpr bool is-signed-integer-like = see below;    // exposition only

template<class I>
  concept weakly_incrementable =
    movable<I> &&
    requires(I i) {
      typename iter_difference_t<I>;
      requires is-signed-integer-like<iter_difference_t<I>>;
      { ++i } -> same_as<I&>;                           // not required to be equality-preserving
      i++;                                              // not required to be equality-preserving
    };
```

2 A type `I` is an *integer-class type* if it is in a set of implementation-defined types that behave as integer types do, as defined below.

[*Note 1*: An integer-class type is not necessarily a class type. — *end note*]

3 The range of representable values of an integer-class type is the continuous set of values over which it is defined. For any integer-class type, its range of representable values is either -2^{N-1} to $2^{N-1}-1$ (inclusive) for some integer N, in which case it is a *signed-integer-class type*, or 0 to 2^N-1 (inclusive) for some integer N, in which case it is an *unsigned-integer-class type*. In both cases, N is called the *width* of the integer-class type. The width of an integer-class type is greater than that of every integral type of the same signedness.

4 A type `I` other than *cv* `bool` is *integer-like* if it models `integral<I>` or if it is an integer-class type. An integer-like type `I` is *signed-integer-like* if it models `signed_integral<I>` or if it is a signed-integer-class

type. An integer-like type `I` is *unsigned-integer-like* if it models `unsigned_integral<I>` or if it is an unsigned-integer-class type.

5 For every integer-class type `I`, let `B(I)` be a unique hypothetical extended integer type of the same signedness with the same width (6.9.2) as `I`.

[*Note 2*: The corresponding hypothetical specialization `numeric_limits<B(I)>` meets the requirements on `numeric_limits` specializations for integral types (17.3.5). — *end note*]

For every integral type `J`, let `B(J)` be the same type as `J`.

6 Expressions of integer-class type are explicitly convertible to any integer-like type, and implicitly convertible to any integer-class type of equal or greater width and the same signedness. Expressions of integral type are both implicitly and explicitly convertible to any integer-class type. Conversions between integral and integer-class types and between two integer-class types do not exit via an exception. The result of such a conversion is the unique value of the destination type that is congruent to the source modulo 2^N, where N is the width of the destination type.

7 Let `a` be an object of integer-class type `I`, let `b` be an object of integer-like type `I2` such that the expression `b` is implicitly convertible to `I`, let `x` and `y` be, respectively, objects of type `B(I)` and `B(I2)` as described above that represent the same values as `a` and `b`, and let `c` be an lvalue of any integral type.

(7.1) — The expressions `a++` and `a--` shall be prvalues of type `I` whose values are equal to that of `a` prior to the evaluation of the expressions. The expression `a++` shall modify the value of `a` by adding `1` to it. The expression `a--` shall modify the value of `a` by subtracting `1` from it.

(7.2) — The expressions `++a`, `--a`, and `&a` shall be expression-equivalent to `a += 1`, `a -= 1`, and `addressof(a)`, respectively.

(7.3) — For every *unary-operator* `@` other than `&` for which the expression `@x` is well-formed, `@a` shall also be well-formed and have the same value, effects, and value category as `@x`. If `@x` has type `bool`, so too does `@a`; if `@x` has type `B(I)`, then `@a` has type `I`.

(7.4) — For every assignment operator `@=` for which `c @= x` is well-formed, `c @= a` shall also be well-formed and shall have the same value and effects as `c @= x`. The expression `c @= a` shall be an lvalue referring to `c`.

(7.5) — For every assignment operator `@=` for which `x @= y` is well-formed, `a @= b` shall also be well-formed and shall have the same effects as `x @= y`, except that the value that would be stored into `x` is stored into `a`. The expression `a @= b` shall be an lvalue referring to `a`.

(7.6) — For every non-assignment binary operator `@` for which `x @ y` and `y @ x` are well-formed, `a @ b` and `b @ a` shall also be well-formed and shall have the same value, effects, and value category as `x @ y` and `y @ x`, respectively. If `x @ y` or `y @ x` has type `B(I)`, then `a @ b` or `b @ a`, respectively, has type `I`; if `x @ y` or `y @ x` has type `B(I2)`, then `a @ b` or `b @ a`, respectively, has type `I2`; if `x @ y` or `y @ x` has any other type, then `a @ b` or `b @ a`, respectively, has that type.

8 An expression `E` of integer-class type `I` is contextually convertible to `bool` as if by `bool(E != I(0))`.

9 All integer-class types model `regular` (18.6) and `three_way_comparable<strong_ordering>` (17.12.4).

10 A value-initialized object of integer-class type has value 0.

11 For every (possibly cv-qualified) integer-class type `I`, `numeric_limits<I>` is specialized such that each static data member `m` has the same value as `numeric_limits<B(I)>::m`, and each static member function `f` returns `I(numeric_limits<B(I)>::f())`.

12 For any two integer-like types `I1` and `I2`, at least one of which is an integer-class type, `common_type_t<I1, I2>` denotes an integer-class type whose width is not less than that of `I1` or `I2`. If both `I1` and `I2` are signed-integer-like types, then `common_type_t<I1, I2>` is also a signed-integer-like type.

13 *`is-integer-like`*`<I>` is `true` if and only if `I` is an integer-like type. *`is-signed-integer-like`*`<I>` is `true` if and only if `I` is a signed-integer-like type.

14 Let `i` be an object of type `I`. When `i` is in the domain of both pre- and post-increment, `i` is said to be *incrementable*. `I` models `weakly_incrementable<I>` only if:

(14.1) — The expressions `++i` and `i++` have the same domain.

(14.2) — If `i` is incrementable, then both `++i` and `i++` advance `i` to the next element.

(14.3) — If `i` is incrementable, then `addressof(++i)` is equal to `addressof(i)`.

15 *Recommended practice*: The implementation of an algorithm on a weakly incrementable type should never attempt to pass through the same incrementable value twice; such an algorithm should be a single-pass algorithm.

[*Note 3*: For `weakly_incrementable` types, `a` equals `b` does not imply that `++a` equals `++b`. (Equality does not guarantee the substitution property or referential transparency.) Such algorithms can be used with istreams as the source of the input data through the `istream_iterator` class template. — *end note*]

24.3.4.5 Concept `incrementable` [iterator.concept.inc]

1 The `incrementable` concept specifies requirements on types that can be incremented with the pre- and post-increment operators. The increment operations are required to be equality-preserving, and the type is required to be `equality_comparable`.

[*Note 1*: This supersedes the "not required to be equality-preserving" comments on the increment expressions in the definition of `weakly_incrementable`. — *end note*]

```
template<class I>
  concept incrementable =
    regular<I> &&
    weakly_incrementable<I> &&
    requires(I i) {
      { i++ } -> same_as<I>;
    };
```

2 Let `a` and `b` be incrementable objects of type `I`. `I` models `incrementable` only if:

(2.1) — If `bool(a == b)` then `bool(a++ == b)`.

(2.2) — If `bool(a == b)` then `bool(((void)a++, a) == ++b)`.

3 [*Note 2*: The requirement that `a` equals `b` implies `++a` equals `++b` (which is not true for weakly incrementable types) allows the use of multi-pass one-directional algorithms with types that model `incrementable`. — *end note*]

24.3.4.6 Concept `input_or_output_iterator` [iterator.concept.iterator]

1 The `input_or_output_iterator` concept forms the basis of the iterator concept taxonomy; every iterator models `input_or_output_iterator`. This concept specifies operations for dereferencing and incrementing an iterator. Most algorithms will require additional operations to compare iterators with sentinels (24.3.4.7), to read (24.3.4.9) or write (24.3.4.10) values, or to provide a richer set of iterator movements (24.3.4.11, 24.3.4.12, 24.3.4.13).

```
template<class I>
  concept input_or_output_iterator =
    requires(I i) {
      { *i } -> can-reference;
    } &&
    weakly_incrementable<I>;
```

2 [*Note 1*: Unlike the *Cpp17Iterator* requirements, the `input_or_output_iterator` concept does not require copyability. — *end note*]

24.3.4.7 Concept `sentinel_for` [iterator.concept.sentinel]

1 The `sentinel_for` concept specifies the relationship between an `input_or_output_iterator` type and a `semiregular` type whose values denote a range.

```
template<class S, class I>
  concept sentinel_for =
    semiregular<S> &&
    !is-integer-like<S> &&
    input_or_output_iterator<I> &&
    weakly-equality-comparable-with<S, I>;      // see 18.5.4
```

2 Let `s` and `i` be values of type `S` and `I` such that $[$`i`, `s`$)$ denotes a range. Types `S` and `I` model `sentinel_for<S, I>` only if:

(2.1) — `i == s` is well-defined.

(2.2) — If `bool(i != s)` then `i` is dereferenceable and $[$`++i`, `s`$)$ denotes a range.

(2.3) — `assignable_from<I&, S>` is either modeled or not satisfied.

(2.4) — If `I` and `S` are the same type, then `i == i` is `true`.

3 The domain of `==` is not static. Given an iterator `i` and sentinel `s` such that $[i, s)$ denotes a range and `i != s`, `i` and `s` are not required to continue to denote a range after incrementing any other iterator equal to `i`. Consequently, `i == s` is no longer required to be well-defined.

24.3.4.8 Concept `sized_sentinel_for` [iterator.concept.sizedsentinel]

1 The `sized_sentinel_for` concept specifies requirements on an `input_or_output_iterator` type `I` and a corresponding `sentinel_for<I>` that allow the use of the `-` operator to compute the distance between them in constant time.

```
template<class S, class I>
  concept sized_sentinel_for =
    sentinel_for<S, I> &&
    !disable_sized_sentinel_for<remove_cv_t<S>, remove_cv_t<I>> &&
    requires(const I& i, const S& s) {
      { s - i } -> same_as<iter_difference_t<I>>;
      { i - s } -> same_as<iter_difference_t<I>>;
    };
```

2 Let `i` be an iterator of type `I`, and `s` a sentinel of type `S` such that $[i, s)$ denotes a range. Let N be the smallest number of applications of `++i` necessary to make `bool(i == s)` be `true`. `S` and `I` model `sized_sentinel_for<S, I>` only if:

(2.1) — If N is representable by `iter_difference_t<I>`, then `s - i` is well-defined and equals N.

(2.2) — If $-N$ is representable by `iter_difference_t<I>`, then `i - s` is well-defined and equals $-N$.

```
template<class S, class I>
  constexpr bool disable_sized_sentinel_for = false;
```

3 *Remarks*: Pursuant to 16.4.5.2.1, users may specialize `disable_sized_sentinel_for` for cv-unqualified non-array object types `S` and `I` if `S` and/or `I` is a program-defined type. Such specializations shall be usable in constant expressions (7.7.4) and have type `const bool`.

4 [*Note 1*: `disable_sized_sentinel_for` allows use of sentinels and iterators with the library that satisfy but do not in fact model `sized_sentinel_for`. — *end note*]

5 [*Example 1*: The `sized_sentinel_for` concept is modeled by pairs of `random_access_iterators` (24.3.4.13) and by counted iterators and their sentinels (24.5.7.1). — *end example*]

24.3.4.9 Concept `input_iterator` [iterator.concept.input]

1 The `input_iterator` concept defines requirements for a type whose referenced values can be read (from the requirement for `indirectly_readable` (24.3.4.2)) and which can be both pre- and post-incremented.

[*Note 1*: Unlike the *Cpp17InputIterator* requirements (24.3.5.3), the `input_iterator` concept does not need equality comparison since iterators are typically compared to sentinels. — *end note*]

```
template<class I>
  concept input_iterator =
    input_or_output_iterator<I> &&
    indirectly_readable<I> &&
    requires { typename ITER_CONCEPT(I); } &&
    derived_from<ITER_CONCEPT(I), input_iterator_tag>;
```

24.3.4.10 Concept `output_iterator` [iterator.concept.output]

1 The `output_iterator` concept defines requirements for a type that can be used to write values (from the requirement for `indirectly_writable` (24.3.4.3)) and which can be both pre- and post-incremented.

[*Note 1*: Output iterators are not required to model `equality_comparable`. — *end note*]

```
template<class I, class T>
  concept output_iterator =
    input_or_output_iterator<I> &&
    indirectly_writable<I, T> &&
    requires(I i, T&& t) {
      *i++ = std::forward<T>(t);        // not required to be equality-preserving
    };
```

2 Let `E` be an expression such that `decltype((E))` is `T`, and let `i` be a dereferenceable object of type `I`. `I` and `T` model `output_iterator<I, T>` only if `*i++ = E;` has effects equivalent to:

```
*i = E;
++i;
```

3 *Recommended practice*: The implementation of an algorithm on output iterators should never attempt to pass through the same iterator twice; such an algorithm should be a single-pass algorithm.

24.3.4.11 Concept `forward_iterator` [iterator.concept.forward]

1 The `forward_iterator` concept adds copyability, equality comparison, and the multi-pass guarantee, specified below.

```
template<class I>
  concept forward_iterator =
    input_iterator<I> &&
    derived_from<ITER_CONCEPT(I), forward_iterator_tag> &&
    incrementable<I> &&
    sentinel_for<I, I>;
```

2 The domain of `==` for forward iterators is that of iterators over the same underlying sequence. However, value-initialized iterators of the same type may be compared and shall compare equal to other value-initialized iterators of the same type.

[*Note 1*: Value-initialized iterators behave as if they refer past the end of the same empty sequence. — *end note*]

3 Pointers and references obtained from a forward iterator into a range $[$`i`, `s`$)$ shall remain valid while $[$`i`, `s`$)$ continues to denote a range.

4 Two dereferenceable iterators `a` and `b` of type `X` offer the *multi-pass guarantee* if

(4.1) — `a == b` implies `++a == ++b` and

(4.2) — the expression `((void)[](X x){++x;}(a), *a)` is equivalent to the expression `*a`.

5 [*Note 2*: The requirement that `a == b` implies `++a == ++b` and the removal of the restrictions on the number of assignments through a mutable iterator (which applies to output iterators) allow the use of multi-pass one-directional algorithms with forward iterators. — *end note*]

24.3.4.12 Concept `bidirectional_iterator` [iterator.concept.bidir]

1 The `bidirectional_iterator` concept adds the ability to move an iterator backward as well as forward.

```
template<class I>
  concept bidirectional_iterator =
    forward_iterator<I> &&
    derived_from<ITER_CONCEPT(I), bidirectional_iterator_tag> &&
    requires(I i) {
      { --i } -> same_as<I&>;
      { i-- } -> same_as<I>;
    };
```

2 A bidirectional iterator `r` is decrementable if and only if there exists some `q` such that `++q == r`. Decrementable iterators `r` shall be in the domain of the expressions `--r` and `r--`.

3 Let `a` and `b` be equal objects of type `I`. `I` models `bidirectional_iterator` only if:

(3.1) — If `a` and `b` are decrementable, then all of the following are `true`:

(3.1.1) — `addressof(--a) == addressof(a)`

(3.1.2) — `bool(a-- == b)`

(3.1.3) — after evaluating both `a--` and `--b`, `bool(a == b)` is still `true`

(3.1.4) — `bool(++(--a) == b)`

(3.2) — If `a` and `b` are incrementable, then `bool(--(++a) == b)`.

24.3.4.13 Concept `random_access_iterator` [iterator.concept.random.access]

1 The `random_access_iterator` concept adds support for constant-time advancement with `+=`, `+`, `-=`, and `-`, as well as the computation of distance in constant time with `-`. Random access iterators also support array notation via subscripting.

```
template<class I>
  concept random_access_iterator =
    bidirectional_iterator<I> &&
    derived_from<ITER_CONCEPT(I), random_access_iterator_tag> &&
    totally_ordered<I> &&
    sized_sentinel_for<I, I> &&
    requires(I i, const I j, const iter_difference_t<I> n) {
      { i += n } -> same_as<I&>;
      { j +  n } -> same_as<I>;
      { n +  j } -> same_as<I>;
      { i -= n } -> same_as<I&>;
      { j -  n } -> same_as<I>;
      {  j[n]  } -> same_as<iter_reference_t<I>>;
    };
```

2 Let `a` and `b` be valid iterators of type `I` such that `b` is reachable from `a` after `n` applications of `++a`, let `D` be `iter_difference_t<I>`, and let `n` denote a value of type `D`. `I` models `random_access_iterator` only if:

(2.1) — `(a += n)` is equal to `b`.

(2.2) — `addressof(a += n)` is equal to `addressof(a)`.

(2.3) — `(a + n)` is equal to `(a += n)`.

(2.4) — For any two positive values `x` and `y` of type `D`, if `(a + D(x + y))` is valid, then `(a + D(x + y))` is equal to `((a + x) + y)`.

(2.5) — `(a + D(0))` is equal to `a`.

(2.6) — If `(a + D(n - 1))` is valid, then `(a + n)` is equal to `[](I c){ return ++c; }(a + D(n - 1))`.

(2.7) — `(b += D(-n))` is equal to `a`.

(2.8) — `(b -= n)` is equal to `a`.

(2.9) — `addressof(b -= n)` is equal to `addressof(b)`.

(2.10) — `(b - n)` is equal to `(b -= n)`.

(2.11) — If `b` is dereferenceable, then `a[n]` is valid and is equal to `*b`.

(2.12) — `bool(a <= b)` is `true`.

24.3.4.14 Concept `contiguous_iterator` [iterator.concept.contiguous]

1 The `contiguous_iterator` concept provides a guarantee that the denoted elements are stored contiguously in memory.

```
template<class I>
  concept contiguous_iterator =
    random_access_iterator<I> &&
    derived_from<ITER_CONCEPT(I), contiguous_iterator_tag> &&
    is_lvalue_reference_v<iter_reference_t<I>> &&
    same_as<iter_value_t<I>, remove_cvref_t<iter_reference_t<I>>> &&
    requires(const I& i) {
      { to_address(i) } -> same_as<add_pointer_t<iter_reference_t<I>>>;
    };
```

2 Let `a` and `b` be dereferenceable iterators and `c` be a non-dereferenceable iterator of type `I` such that `b` is reachable from `a` and `c` is reachable from `b`, and let `D` be `iter_difference_t<I>`. The type `I` models `contiguous_iterator` only if

(2.1) — `to_address(a) == addressof(*a)`,

(2.2) — `to_address(b) == to_address(a) + D(b - a)`,

(2.3) — `to_address(c) == to_address(a) + D(c - a)`,

(2.4) — `to_address(I{})` is well-defined,

(2.5) — `ranges::iter_move(a)` has the same type, value category, and effects as `std::move(*a)`, and

(2.6) — if `ranges::iter_swap(a, b)` is well-formed, it has effects equivalent to `ranges::swap(*a, *b)`.

24.3.5 C++17 iterator requirements [iterator.cpp17]

24.3.5.1 General [iterator.cpp17.general]

1 In the following sections, `a` and `b` denote values of type `X` or `const X`, `difference_type` and `reference` refer to the types `iterator_traits<X>::difference_type` and `iterator_traits<X>::reference`, respectively, `n` denotes a value of `difference_type`, `u`, `tmp`, and `m` denote identifiers, `r` denotes a value of `X&`, `t` denotes a value of value type `T`, `o` denotes a value of some type that is writable to the output iterator.

[*Note 1*: For an iterator type `X` there must be an instantiation of `iterator_traits<X>` (24.3.2.3). — *end note*]

24.3.5.2 *Cpp17Iterator* [iterator.iterators]

1 The *Cpp17Iterator* requirements form the basis of the iterator taxonomy; every iterator meets the *Cpp17Iterator* requirements. This set of requirements specifies operations for dereferencing and incrementing an iterator. Most algorithms will require additional operations to read (24.3.5.3) or write (24.3.5.4) values, or to provide a richer set of iterator movements (24.3.5.5, 24.3.5.6, 24.3.5.7).

2 A type `X` meets the *Cpp17Iterator* requirements if

(2.1) — `X` meets the *Cpp17CopyConstructible*, *Cpp17CopyAssignable*, *Cpp17Swappable*, and *Cpp17Destructible* requirements (16.4.4.2, 16.4.4.3), and

(2.2) — `iterator_traits<X>::difference_type` is a signed integer type or `void`, and

(2.3) — the expressions in Table 78 are valid and have the indicated semantics.

Table 78 — *Cpp17Iterator* requirements [tab:iterator]

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
`*r`	unspecified		*Preconditions*: `r` is dereferenceable.
`++r`	`X&`		

24.3.5.3 Input iterators [input.iterators]

1 A class or pointer type `X` meets the requirements of an input iterator for the value type `T` if `X` meets the *Cpp17Iterator* (24.3.5.2) and *Cpp17EqualityComparable* (Table 28) requirements and the expressions in Table 79 are valid and have the indicated semantics.

2 In Table 79, the term *the domain of* `==` is used in the ordinary mathematical sense to denote the set of values over which `==` is (required to be) defined. This set can change over time. Each algorithm places additional requirements on the domain of `==` for the iterator values it uses. These requirements can be inferred from the uses that algorithm makes of `==` and `!=`.

[*Example 1*: The call `find(a,b,x)` is defined only if the value of `a` has the property p defined as follows: `b` has property p and a value `i` has property p if (`*i==x`) or if (`*i!=x` and `++i` has property p). — *end example*]

Table 79 — *Cpp17InputIterator* requirements (in addition to *Cpp17Iterator*) [tab:inputiterator]

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
`a != b`	`decltype(a != b)` models *boolean-testable*	`!(a == b)`	*Preconditions*: `(a, b)` is in the domain of `==`.

Table 79 — *Cpp17InputIterator* requirements (in addition to *Cpp17Iterator*) (continued)

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
`*a`	`reference`, convertible to `T`		*Preconditions*: `a` is dereferenceable. The expression `(void)*a, *a` is equivalent to `*a`. If `a == b` and `(a, b)` is in the domain of `==` then `*a` is equivalent to `*b`.
`a->m`		`(*a).m`	*Preconditions*: `a` is dereferenceable.
`++r`	`X&`		*Preconditions*: `r` is dereferenceable. *Postconditions*: `r` is dereferenceable or `r` is past-the-end; any copies of the previous value of `r` are no longer required to be dereferenceable nor to be in the domain of `==`.
`(void)r++`			equivalent to `(void)++r`
`*r++`	convertible to `T`	`{ T tmp = *r; ++r; return tmp; }`	

3 *Recommended practice*: The implementation of an algorithm on input iterators should never attempt to pass through the same iterator twice; such an algorithm should be a single pass algorithm.

[*Note 1*: For input iterators, `a == b` does not imply `++a == ++b`. (Equality does not guarantee the substitution property or referential transparency.) Value type `T` is not required to be a *Cpp17CopyAssignable* type (Table 34). Such an algorithm can be used with istreams as the source of the input data through the `istream_iterator` class template. — *end note*]

24.3.5.4 Output iterators [output.iterators]

1 A class or pointer type `X` meets the requirements of an output iterator if `X` meets the *Cpp17Iterator* requirements (24.3.5.2) and the expressions in Table 80 are valid and have the indicated semantics.

2 *Recommended practice*: The implementation of an algorithm on output iterators should never attempt to pass through the same iterator twice; such an algorithm should be a single-pass algorithm.

[*Note 1*: The only valid use of an `operator*` is on the left side of the assignment statement. Assignment through the same value of the iterator happens only once. Equality and inequality are not necessarily defined. — *end note*]

24.3.5.5 Forward iterators [forward.iterators]

1 A class or pointer type `X` meets the *Cpp17ForwardIterator* requirements if

(1.1) — `X` meets the *Cpp17InputIterator* requirements (24.3.5.3),

(1.2) — `X` meets the *Cpp17DefaultConstructible* requirements (16.4.4.2),

(1.3) — if `X` is a mutable iterator, `reference` is a reference to `T`; if `X` is a constant iterator, `reference` is a reference to `const T`,

(1.4) — the expressions in Table 81 are valid and have the indicated semantics, and

(1.5) — objects of type `X` offer the multi-pass guarantee, described below.

2 The domain of `==` for forward iterators is that of iterators over the same underlying sequence. However, value-initialized iterators may be compared and shall compare equal to other value-initialized iterators of the same type.

Table 80 — *Cpp17OutputIterator* requirements (in addition to *Cpp17Iterator*) [tab:outputiterator]

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
`*r = o`	result is not used		*Remarks*: After this operation `r` is not required to be dereferenceable. *Postconditions*: `r` is incrementable.
`++r`	`X&`		`addressof(r) == addressof(++r)`. *Remarks*: After this operation `r` is not required to be dereferenceable. *Postconditions*: `r` is incrementable.
`r++`	convertible to `const X&`	`{ X tmp = r; ++r; return tmp; }`	*Remarks*: After this operation `r` is not required to be dereferenceable. *Postconditions*: `r` is incrementable.
`*r++ = o`	result is not used		*Remarks*: After this operation `r` is not required to be dereferenceable. *Postconditions*: `r` is incrementable.

[*Note 1*: Value-initialized iterators behave as if they refer past the end of the same empty sequence. — *end note*]

3 Two dereferenceable iterators `a` and `b` of type `X` offer the *multi-pass guarantee* if

(3.1) — `a == b` implies `++a == ++b` and

(3.2) — `X` is a pointer type or the expression `(void)++X(a), *a` is equivalent to the expression `*a`.

4 [*Note 2*: The requirement that `a == b` implies `++a == ++b` (which is not true for input and output iterators) and the removal of the restrictions on the number of the assignments through a mutable iterator (which applies to output iterators) allows the use of multi-pass one-directional algorithms with forward iterators. — *end note*]

Table 81 — *Cpp17ForwardIterator* requirements (in addition to *Cpp17InputIterator*) [tab:forwarditerator]

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
`r++`	convertible to `const X&`	`{ X tmp = r; ++r; return tmp; }`	
`*r++`	`reference`		

5 If `a` and `b` are equal, then either `a` and `b` are both dereferenceable or else neither is dereferenceable.

6 If `a` and `b` are both dereferenceable, then `a == b` if and only if `*a` and `*b` are bound to the same object.

24.3.5.6 Bidirectional iterators [bidirectional.iterators]

1 A class or pointer type `X` meets the requirements of a bidirectional iterator if, in addition to meeting the *Cpp17ForwardIterator* requirements, the following expressions are valid as shown in Table 82.

2 [*Note 1*: Bidirectional iterators allow algorithms to move iterators backward as well as forward. — *end note*]

Table 82 — *Cpp17BidirectionalIterator* requirements (in addition to *Cpp17ForwardIterator*) [tab:bidirectionaliterator]

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
`--r`	`X&`		*Preconditions*: there exists `s` such that `r == ++s`. *Postconditions*: `r` is dereferenceable. `--(++r) == r`. `--r == --s` implies `r == s`. `addressof(r) == addressof(--r)`.
`r--`	convertible to `const X&`	`{ X tmp = r; --r; return tmp; }`	
`*r--`	`reference`		

24.3.5.7 Random access iterators [random.access.iterators]

1 A class or pointer type `X` meets the requirements of a random access iterator if, in addition to meeting the *Cpp17BidirectionalIterator* requirements, the following expressions are valid as shown in Table 83.

Table 83 — *Cpp17RandomAccessIterator* requirements (in addition to *Cpp17BidirectionalIterator*) [tab:randomaccessiterator]

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
`r += n`	`X&`	`{ difference_type m = n; if (m >= 0) while (m--) ++r; else while (m++) --r; return r; }`	
`a + n` `n + a`	`X`	`{ X tmp = a; return tmp += n; }`	`a + n == n + a`.
`r -= n`	`X&`	`return r += -n;`	*Preconditions*: the absolute value of `n` is in the range of representable values of `difference_type`.
`a - n`	`X`	`{ X tmp = a; return tmp -= n; }`	
`b - a`	`difference_type`	`return n;`	*Preconditions*: there exists a value `n` of type `difference_type` such that `a + n == b`. `b == a + (b - a)`.
`a[n]`	convertible to `reference`	`*(a + n)`	
`a < b`	`decltype(a < b)` models *`boolean-testable`*	*Effects*: Equivalent to: `return b - a > 0;`	`<` is a total ordering relation

Table 83 — *Cpp17RandomAccessIterator* requirements (in addition to *Cpp17BidirectionalIterator*) (continued)

Expression	Return type	Operational semantics	Assertion/note pre-/post-condition
`a > b`	`decltype(a > b)` models *boolean-testable*	`b < a`	`>` is a total ordering relation opposite to `<`.
`a >= b`	`decltype(a >= b)` models *boolean-testable*	`!(a < b)`	
`a <= b`	`decltype(a <= b)` models *boolean-testable*	`!(a > b)`	

24.3.6 Indirect callable requirements [indirectcallable]

24.3.6.1 General [indirectcallable.general]

1 There are several concepts that group requirements of algorithms that take callable objects (22.10.3) as arguments.

24.3.6.2 Indirect callable traits [indirectcallable.traits]

1 To implement algorithms taking projections, it is necessary to determine the projected type of an iterator's value type. For the exposition-only alias template *indirect-value-t*, *indirect-value-t*<T> denotes

(1.1) — `invoke_result_t<Proj&, `*indirect-value-t*`<I>>` if `T` names `projected<I, Proj>`, and

(1.2) — `iter_value_t<T>&` otherwise.

24.3.6.3 Indirect callables [indirectcallable.indirectinvocable]

1 The indirect callable concepts are used to constrain those algorithms that accept callable objects (22.10.3) as arguments.

```
namespace std {
  template<class F, class I>
    concept indirectly_unary_invocable =
      indirectly_readable<I> &&
      copy_constructible<F> &&
      invocable<F&, indirect-value-t<I>> &&
      invocable<F&, iter_reference_t<I>> &&
      common_reference_with<
        invoke_result_t<F&, indirect-value-t<I>>,
        invoke_result_t<F&, iter_reference_t<I>>>;

  template<class F, class I>
    concept indirectly_regular_unary_invocable =
      indirectly_readable<I> &&
      copy_constructible<F> &&
      regular_invocable<F&, indirect-value-t<I>> &&
      regular_invocable<F&, iter_reference_t<I>> &&
      common_reference_with<
        invoke_result_t<F&, indirect-value-t<I>>,
        invoke_result_t<F&, iter_reference_t<I>>>;

  template<class F, class I>
    concept indirect_unary_predicate =
      indirectly_readable<I> &&
      copy_constructible<F> &&
      predicate<F&, indirect-value-t<I>> &&
      predicate<F&, iter_reference_t<I>>;
```

```
  template<class F, class I1, class I2>
    concept indirect_binary_predicate =
      indirectly_readable<I1> && indirectly_readable<I2> &&
      copy_constructible<F> &&
      predicate<F&, indirect-value-t<I1>, indirect-value-t<I2>> &&
      predicate<F&, indirect-value-t<I1>, iter_reference_t<I2>> &&
      predicate<F&, iter_reference_t<I1>, indirect-value-t<I2>> &&
      predicate<F&, iter_reference_t<I1>, iter_reference_t<I2>>;

  template<class F, class I1, class I2 = I1>
    concept indirect_equivalence_relation =
      indirectly_readable<I1> && indirectly_readable<I2> &&
      copy_constructible<F> &&
      equivalence_relation<F&, indirect-value-t<I1>, indirect-value-t<I2>> &&
      equivalence_relation<F&, indirect-value-t<I1>, iter_reference_t<I2>> &&
      equivalence_relation<F&, iter_reference_t<I1>, indirect-value-t<I2>> &&
      equivalence_relation<F&, iter_reference_t<I1>, iter_reference_t<I2>>;

  template<class F, class I1, class I2 = I1>
    concept indirect_strict_weak_order =
      indirectly_readable<I1> && indirectly_readable<I2> &&
      copy_constructible<F> &&
      strict_weak_order<F&, indirect-value-t<I1>, indirect-value-t<I2>> &&
      strict_weak_order<F&, indirect-value-t<I1>, iter_reference_t<I2>> &&
      strict_weak_order<F&, iter_reference_t<I1>, indirect-value-t<I2>> &&
      strict_weak_order<F&, iter_reference_t<I1>, iter_reference_t<I2>>;
}
```

24.3.6.4 Alias template `projected` [projected]

1 Alias template `projected` is used to constrain algorithms that accept callable objects and projections (3.44). It combines an `indirectly_readable` type `I` and a callable object type `Proj` into a new `indirectly_readable` type whose `reference` type is the result of applying `Proj` to the `iter_reference_t` of `I`.

```
namespace std {
  template<class I, class Proj>
  struct projected-impl {                                  // exposition only
    struct type {                                          // exposition only
      using value_type = remove_cvref_t<indirect_result_t<Proj&, I>>;
      using difference_type = iter_difference_t<I>;        // present only if I
                                                           // models weakly_incrementable
      indirect_result_t<Proj&, I> operator*() const;       // not defined
    };
  };

  template<indirectly_readable I, indirectly_regular_unary_invocable<I> Proj>
    using projected = projected-impl<I, Proj>::type;
}
```

24.3.7 Common algorithm requirements [alg.req]

24.3.7.1 General [alg.req.general]

1 There are several additional iterator concepts that are commonly applied to families of algorithms. These group together iterator requirements of algorithm families. There are three relational concepts that specify how element values are transferred between `indirectly_readable` and `indirectly_writable` types: `indirectly_movable`, `indirectly_copyable`, and `indirectly_swappable`. There are three relational concepts for rearrangements: `permutable`, `mergeable`, and `sortable`. There is one relational concept for comparing values from different sequences: `indirectly_comparable`.

2 [*Note 1*: The `ranges::less` function object type used in the concepts below imposes constraints on the concepts' arguments in addition to those that appear in the concepts' bodies (22.10.9). — *end note*]

24.3.7.2 Concept `indirectly_movable` [alg.req.ind.move]

1 The `indirectly_movable` concept specifies the relationship between an `indirectly_readable` type and an `indirectly_writable` type between which values may be moved.

```
template<class In, class Out>
  concept indirectly_movable =
    indirectly_readable<In> &&
    indirectly_writable<Out, iter_rvalue_reference_t<In>>;
```

[2] The `indirectly_movable_storable` concept augments `indirectly_movable` with additional requirements enabling the transfer to be performed through an intermediate object of the `indirectly_readable` type's value type.

```
template<class In, class Out>
  concept indirectly_movable_storable =
    indirectly_movable<In, Out> &&
    indirectly_writable<Out, iter_value_t<In>> &&
    movable<iter_value_t<In>> &&
    constructible_from<iter_value_t<In>, iter_rvalue_reference_t<In>> &&
    assignable_from<iter_value_t<In>&, iter_rvalue_reference_t<In>>;
```

[3] Let `i` be a dereferenceable value of type `In`. `In` and `Out` model `indirectly_movable_storable<In, Out>` only if after the initialization of the object `obj` in

```
iter_value_t<In> obj(ranges::iter_move(i));
```

`obj` is equal to the value previously denoted by `*i`. If `iter_rvalue_reference_t<In>` is an rvalue reference type, the resulting state of the value denoted by `*i` is valid but unspecified (16.4.6.17).

24.3.7.3 Concept `indirectly_copyable` [alg.req.ind.copy]

[1] The `indirectly_copyable` concept specifies the relationship between an `indirectly_readable` type and an `indirectly_writable` type between which values may be copied.

```
template<class In, class Out>
  concept indirectly_copyable =
    indirectly_readable<In> &&
    indirectly_writable<Out, iter_reference_t<In>>;
```

[2] The `indirectly_copyable_storable` concept augments `indirectly_copyable` with additional requirements enabling the transfer to be performed through an intermediate object of the `indirectly_readable` type's value type. It also requires the capability to make copies of values.

```
template<class In, class Out>
  concept indirectly_copyable_storable =
    indirectly_copyable<In, Out> &&
    indirectly_writable<Out, iter_value_t<In>&> &&
    indirectly_writable<Out, const iter_value_t<In>&> &&
    indirectly_writable<Out, iter_value_t<In>&&> &&
    indirectly_writable<Out, const iter_value_t<In>&&> &&
    copyable<iter_value_t<In>> &&
    constructible_from<iter_value_t<In>, iter_reference_t<In>> &&
    assignable_from<iter_value_t<In>&, iter_reference_t<In>>;
```

[3] Let `i` be a dereferenceable value of type `In`. `In` and `Out` model `indirectly_copyable_storable<In, Out>` only if after the initialization of the object `obj` in

```
iter_value_t<In> obj(*i);
```

`obj` is equal to the value previously denoted by `*i`. If `iter_reference_t<In>` is an rvalue reference type, the resulting state of the value denoted by `*i` is valid but unspecified (16.4.6.17).

24.3.7.4 Concept `indirectly_swappable` [alg.req.ind.swap]

[1] The `indirectly_swappable` concept specifies a swappable relationship between the values referenced by two `indirectly_readable` types.

```
template<class I1, class I2 = I1>
  concept indirectly_swappable =
    indirectly_readable<I1> && indirectly_readable<I2> &&
    requires(const I1 i1, const I2 i2) {
      ranges::iter_swap(i1, i1);
      ranges::iter_swap(i2, i2);
      ranges::iter_swap(i1, i2);
      ranges::iter_swap(i2, i1);
```

```
};
```

24.3.7.5 Concept `indirectly_comparable` [alg.req.ind.cmp]

1 The `indirectly_comparable` concept specifies the common requirements of algorithms that compare values from two different sequences.

```
template<class I1, class I2, class R, class P1 = identity,
         class P2 = identity>
  concept indirectly_comparable =
    indirect_binary_predicate<R, projected<I1, P1>, projected<I2, P2>>;
```

24.3.7.6 Concept `permutable` [alg.req.permutable]

1 The `permutable` concept specifies the common requirements of algorithms that reorder elements in place by moving or swapping them.

```
template<class I>
  concept permutable =
    forward_iterator<I> &&
    indirectly_movable_storable<I, I> &&
    indirectly_swappable<I, I>;
```

24.3.7.7 Concept `mergeable` [alg.req.mergeable]

1 The `mergeable` concept specifies the requirements of algorithms that merge sorted sequences into an output sequence by copying elements.

```
template<class I1, class I2, class Out, class R = ranges::less,
         class P1 = identity, class P2 = identity>
  concept mergeable =
    input_iterator<I1> &&
    input_iterator<I2> &&
    weakly_incrementable<Out> &&
    indirectly_copyable<I1, Out> &&
    indirectly_copyable<I2, Out> &&
    indirect_strict_weak_order<R, projected<I1, P1>, projected<I2, P2>>;
```

24.3.7.8 Concept `sortable` [alg.req.sortable]

1 The `sortable` concept specifies the common requirements of algorithms that permute sequences into ordered sequences (e.g., `sort`).

```
template<class I, class R = ranges::less, class P = identity>
  concept sortable =
    permutable<I> &&
    indirect_strict_weak_order<R, projected<I, P>>;
```

24.4 Iterator primitives [iterator.primitives]

24.4.1 General [iterator.primitives.general]

1 To simplify the use of iterators, the library provides several classes and functions.

24.4.2 Standard iterator tags [std.iterator.tags]

1 It is often desirable for a function template specialization to find out what is the most specific category of its iterator argument, so that the function can select the most efficient algorithm at compile time. To facilitate this, the library introduces *category tag* classes which are used as compile time tags for algorithm selection. They are: `output_iterator_tag`, `input_iterator_tag`, `forward_iterator_tag`, `bidirectional_iterator_tag`, `random_access_iterator_tag`, and `contiguous_iterator_tag`. For every iterator of type `I`, `iterator_traits<I>::iterator_category` shall be declared to be a category tag that describes the iterator's behavior. Additionally, `iterator_traits<I>::iterator_concept` may be used to indicate conformance to the iterator concepts (24.3.4).

```
namespace std {
  struct output_iterator_tag { };
  struct input_iterator_tag { };
  struct forward_iterator_tag: public input_iterator_tag { };
  struct bidirectional_iterator_tag: public forward_iterator_tag { };
```

```
  struct random_access_iterator_tag: public bidirectional_iterator_tag { };
  struct contiguous_iterator_tag: public random_access_iterator_tag { };
}
```

2 [*Example 1*: A program-defined iterator `BinaryTreeIterator` can be included into the bidirectional iterator category by specializing the `iterator_traits` template:

```
template<class T> struct iterator_traits<BinaryTreeIterator<T>> {
  using iterator_category = bidirectional_iterator_tag;
  using difference_type   = ptrdiff_t;
  using value_type        = T;
  using pointer           = T*;
  using reference         = T&;
};
```

— *end example*]

3 [*Example 2*: If `evolve()` is well-defined for bidirectional iterators, but can be implemented more efficiently for random access iterators, then the implementation is as follows:

```
template<class BidirectionalIterator>
inline void
evolve(BidirectionalIterator first, BidirectionalIterator last) {
  evolve(first, last,
    typename iterator_traits<BidirectionalIterator>::iterator_category());
}

template<class BidirectionalIterator>
void evolve(BidirectionalIterator first, BidirectionalIterator last,
  bidirectional_iterator_tag) {
  // more generic, but less efficient algorithm
}

template<class RandomAccessIterator>
void evolve(RandomAccessIterator first, RandomAccessIterator last,
  random_access_iterator_tag) {
  // more efficient, but less generic algorithm
}
```

— *end example*]

24.4.3 Iterator operations [iterator.operations]

1 Since only random access iterators provide `+` and `-` operators, the library provides two function templates `advance` and `distance`. These function templates use `+` and `-` for random access iterators (and are, therefore, constant time for them); for input, forward and bidirectional iterators they use `++` to provide linear time implementations.

```
template<class InputIterator, class Distance>
  constexpr void advance(InputIterator& i, Distance n);
```

2 *Preconditions*: `n` is negative only for bidirectional iterators.

3 *Effects*: Increments `i` by `n` if `n` is non-negative, and decrements `i` by `-n` otherwise.

```
template<class InputIterator>
  constexpr typename iterator_traits<InputIterator>::difference_type
    distance(InputIterator first, InputIterator last);
```

4 *Preconditions*: `last` is reachable from `first`, or `InputIterator` meets the *Cpp17RandomAccessIterator* requirements and `first` is reachable from `last`.

5 *Effects*: If `InputIterator` meets the *Cpp17RandomAccessIterator* requirements, returns `(last - first)`; otherwise, increments `first` until `last` is reached and returns the number of increments.

```
template<class InputIterator>
  constexpr InputIterator next(InputIterator x,
    typename iterator_traits<InputIterator>::difference_type n = 1);
```

6 *Effects*: Equivalent to: `advance(x, n); return x;`

```
template<class BidirectionalIterator>
  constexpr BidirectionalIterator prev(BidirectionalIterator x,
    typename iterator_traits<BidirectionalIterator>::difference_type n = 1);
```

7 *Effects*: Equivalent to: `advance(x, -n); return x;`

24.4.4 Range iterator operations [range.iter.ops]

24.4.4.1 General [range.iter.ops.general]

1 The library includes the function templates `ranges::advance`, `ranges::distance`, `ranges::next`, and `ranges::prev` to manipulate iterators. These operations adapt to the set of operators provided by each iterator category to provide the most efficient implementation possible for a concrete iterator type.

[*Example 1*: `ranges::advance` uses the `+` operator to move a `random_access_iterator` forward `n` steps in constant time. For an iterator type that does not model `random_access_iterator`, `ranges::advance` instead performs `n` individual increments with the `++` operator. — *end example*]

2 The entities defined in 24.4.4 are algorithm function objects (16.3.3.4).

24.4.4.2 `ranges::advance` [range.iter.op.advance]

```
template<input_or_output_iterator I>
  constexpr void ranges::advance(I& i, iter_difference_t<I> n);
```

1 *Preconditions*: If `I` does not model `bidirectional_iterator`, `n` is not negative.

2 *Effects*:

(2.1) — If `I` models `random_access_iterator`, equivalent to `i += n`.

(2.2) — Otherwise, if `n` is non-negative, increments `i` by `n`.

(2.3) — Otherwise, decrements `i` by `-n`.

```
template<input_or_output_iterator I, sentinel_for<I> S>
  constexpr void ranges::advance(I& i, S bound);
```

3 *Preconditions*: Either `assignable_from<I&, S> || sized_sentinel_for<S, I>` is modeled, or [`i`, `bound`) denotes a range.

4 *Effects*:

(4.1) — If `I` and `S` model `assignable_from<I&, S>`, equivalent to `i = std::move(bound)`.

(4.2) — Otherwise, if `S` and `I` model `sized_sentinel_for<S, I>`, equivalent to `ranges::advance(i, bound - i)`.

(4.3) — Otherwise, while `bool(i != bound)` is `true`, increments `i`.

```
template<input_or_output_iterator I, sentinel_for<I> S>
  constexpr iter_difference_t<I> ranges::advance(I& i, iter_difference_t<I> n, S bound);
```

5 *Preconditions*: If `n > 0`, [`i`, `bound`) denotes a range. If `n == 0`, [`i`, `bound`) or [`bound`, `i`) denotes a range. If `n < 0`, [`bound`, `i`) denotes a range, `I` models `bidirectional_iterator`, and `I` and `S` model `same_as<I, S>`.

6 *Effects*:

(6.1) — If `S` and `I` model `sized_sentinel_for<S, I>`:

(6.1.1) — If $|$`n`$| \geq |$`bound - i`$|$, equivalent to `ranges::advance(i, bound)`.

(6.1.2) — Otherwise, equivalent to `ranges::advance(i, n)`.

(6.2) — Otherwise,

(6.2.1) — if `n` is non-negative, while `bool(i != bound)` is `true`, increments `i` but at most `n` times.

(6.2.2) — Otherwise, while `bool(i != bound)` is `true`, decrements `i` but at most `-n` times.

7 *Returns*: `n - `M, where M is the difference between the ending and starting positions of `i`.

24.4.4.3 `ranges::distance` [range.iter.op.distance]

```
template<class I, sentinel_for<I> S>
  requires (!sized_sentinel_for<S, I>)
  constexpr iter_difference_t<I> ranges::distance(I first, S last);
```

1 *Preconditions*: [`first`, `last`) denotes a range.

2 *Effects*: Increments `first` until `last` is reached and returns the number of increments.

```
template<class I, sized_sentinel_for<decay_t<I>> S>
  constexpr iter_difference_t<decay_t<I>> ranges::distance(I&& first, S last);
```

3 *Effects*: Equivalent to:

```
if constexpr (!is_array_v<remove_reference_t<I>>)
  return last - first;
else
  return last - static_cast<decay_t<I>>(first);
```

```
template<range R>
  constexpr range_difference_t<R> ranges::distance(R&& r);
```

4 *Effects*: If `R` models `sized_range`, equivalent to:

```
return static_cast<range_difference_t<R>>(ranges::size(r));      // 25.3.10
```

Otherwise, equivalent to:

```
return ranges::distance(ranges::begin(r), ranges::end(r));      // 25.3
```

24.4.4.4 `ranges::next` [range.iter.op.next]

```
template<input_or_output_iterator I>
  constexpr I ranges::next(I x);
```

1 *Effects*: Equivalent to: `++x; return x;`

```
template<input_or_output_iterator I>
  constexpr I ranges::next(I x, iter_difference_t<I> n);
```

2 *Effects*: Equivalent to: `ranges::advance(x, n); return x;`

```
template<input_or_output_iterator I, sentinel_for<I> S>
  constexpr I ranges::next(I x, S bound);
```

3 *Effects*: Equivalent to: `ranges::advance(x, bound); return x;`

```
template<input_or_output_iterator I, sentinel_for<I> S>
  constexpr I ranges::next(I x, iter_difference_t<I> n, S bound);
```

4 *Effects*: Equivalent to: `ranges::advance(x, n, bound); return x;`

24.4.4.5 `ranges::prev` [range.iter.op.prev]

```
template<bidirectional_iterator I>
  constexpr I ranges::prev(I x);
```

1 *Effects*: Equivalent to: `--x; return x;`

```
template<bidirectional_iterator I>
  constexpr I ranges::prev(I x, iter_difference_t<I> n);
```

2 *Effects*: Equivalent to: `ranges::advance(x, -n); return x;`

```
template<bidirectional_iterator I>
  constexpr I ranges::prev(I x, iter_difference_t<I> n, I bound);
```

3 *Effects*: Equivalent to: `ranges::advance(x, -n, bound); return x;`

24.5 Iterator adaptors [predef.iterators]

24.5.1 Reverse iterators [reverse.iterators]

24.5.1.1 General [reverse.iterators.general]

1 Class template `reverse_iterator` is an iterator adaptor that iterates from the end of the sequence defined by its underlying iterator to the beginning of that sequence.

24.5.1.2 Class template `reverse_iterator` [reverse.iterator]

```
namespace std {
  template<class Iterator>
  class reverse_iterator {
  public:
    using iterator_type     = Iterator;
    using iterator_concept  = see below;
    using iterator_category = see below;
    using value_type        = iter_value_t<Iterator>;
    using difference_type   = iter_difference_t<Iterator>;
    using pointer           = iterator_traits<Iterator>::pointer;
    using reference         = iter_reference_t<Iterator>;

    constexpr reverse_iterator();
    constexpr explicit reverse_iterator(Iterator x);
    template<class U> constexpr reverse_iterator(const reverse_iterator<U>& u);
    template<class U> constexpr reverse_iterator& operator=(const reverse_iterator<U>& u);

    constexpr Iterator base() const;
    constexpr reference operator*() const;
    constexpr pointer   operator->() const requires see below;

    constexpr reverse_iterator& operator++();
    constexpr reverse_iterator  operator++(int);
    constexpr reverse_iterator& operator--();
    constexpr reverse_iterator  operator--(int);

    constexpr reverse_iterator  operator+ (difference_type n) const;
    constexpr reverse_iterator& operator+=(difference_type n);
    constexpr reverse_iterator  operator- (difference_type n) const;
    constexpr reverse_iterator& operator-=(difference_type n);
    constexpr unspecified operator[](difference_type n) const;

    friend constexpr iter_rvalue_reference_t<Iterator>
      iter_move(const reverse_iterator& i) noexcept(see below);
    template<indirectly_swappable<Iterator> Iterator2>
      friend constexpr void
        iter_swap(const reverse_iterator& x,
                  const reverse_iterator<Iterator2>& y) noexcept(see below);

  protected:
    Iterator current;
  };
}
```

1 The member *typedef-name* `iterator_concept` denotes

(1.1) — `random_access_iterator_tag` if `Iterator` models `random_access_iterator`, and

(1.2) — `bidirectional_iterator_tag` otherwise.

2 The member *typedef-name* `iterator_category` denotes

(2.1) — `random_access_iterator_tag` if the type `iterator_traits<Iterator>::iterator_category` models `derived_from<random_access_iterator_tag>`, and

(2.2) — `iterator_traits<Iterator>::iterator_category` otherwise.

24.5.1.3 Requirements [reverse.iter.requirements]

1 The template parameter `Iterator` shall either meet the requirements of a *Cpp17BidirectionalIterator* (24.3.5.6) or model `bidirectional_iterator` (24.3.4.12).

2 Additionally, `Iterator` shall either meet the requirements of a *Cpp17RandomAccessIterator* (24.3.5.7) or model `random_access_iterator` (24.3.4.13) if the definitions of any of the members

(2.1) — `operator+`, `operator-`, `operator+=`, `operator-=` (24.5.1.7), or

(2.2) — `operator[]` (24.5.1.6),

or the non-member operators (24.5.1.8)

(2.3) — `operator<`, `operator>`, `operator<=`, `operator>=`, `operator-`, or `operator+` (24.5.1.9)

are instantiated (13.9.2).

24.5.1.4 Construction and assignment [reverse.iter.cons]

```
constexpr reverse_iterator();
```

1 *Effects*: Value-initializes `current`.

```
constexpr explicit reverse_iterator(Iterator x);
```

2 *Effects*: Initializes `current` with `x`.

```
template<class U> constexpr reverse_iterator(const reverse_iterator<U>& u);
```

3 *Constraints*: `is_same_v<U, Iterator>` is `false` and `const U&` models `convertible_to<Iterator>`.

4 *Effects*: Initializes `current` with `u.current`.

```
template<class U>
  constexpr reverse_iterator&
    operator=(const reverse_iterator<U>& u);
```

5 *Constraints*: `is_same_v<U, Iterator>` is `false`, `const U&` models `convertible_to<Iterator>`, and `assignable_from<Iterator&, const U&>` is modeled.

6 *Effects*: Assigns `u.current` to `current`.

7 *Returns*: `*this`.

24.5.1.5 Conversion [reverse.iter.conv]

```
constexpr Iterator base() const;
```

1 *Returns*: `current`.

24.5.1.6 Element access [reverse.iter.elem]

```
constexpr reference operator*() const;
```

1 *Effects*: As if by:

```
Iterator tmp = current;
return *--tmp;
```

```
constexpr pointer operator->() const
  requires (is_pointer_v<Iterator> ||
            requires(const Iterator i) { i.operator->(); });
```

2 *Effects*:

(2.1) — If `Iterator` is a pointer type, equivalent to: `return prev(current);`

(2.2) — Otherwise, equivalent to: `return prev(current).operator->();`

```
constexpr unspecified operator[](difference_type n) const;
```

3 *Returns*: `current[-n - 1]`.

24.5.1.7 Navigation [reverse.iter.nav]

```
constexpr reverse_iterator operator+(difference_type n) const;
```

1 *Returns*: `reverse_iterator(current - n)`.

```
constexpr reverse_iterator operator-(difference_type n) const;
```

2 *Returns*: `reverse_iterator(current + n)`.

```
constexpr reverse_iterator& operator++();
```

3 *Effects*: As if by: `--current;`

4 *Returns*: `*this`.

```
constexpr reverse_iterator operator++(int);
```

5 *Effects*: As if by:

```
reverse_iterator tmp = *this;
--current;
return tmp;
```

```
constexpr reverse_iterator& operator--();
```

6 *Effects*: As if by `++current`.

7 *Returns*: `*this`.

```
constexpr reverse_iterator operator--(int);
```

8 *Effects*: As if by:

```
reverse_iterator tmp = *this;
++current;
return tmp;
```

```
constexpr reverse_iterator& operator+=(difference_type n);
```

9 *Effects*: As if by: `current -= n;`

10 *Returns*: `*this`.

```
constexpr reverse_iterator& operator-=(difference_type n);
```

11 *Effects*: As if by: `current += n;`

12 *Returns*: `*this`.

24.5.1.8 Comparisons [reverse.iter.cmp]

```
template<class Iterator1, class Iterator2>
  constexpr bool operator==(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);
```

1 *Constraints*: `x.base() == y.base()` is well-formed and convertible to `bool`.

2 *Returns*: `x.base() == y.base()`.

```
template<class Iterator1, class Iterator2>
  constexpr bool operator!=(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);
```

3 *Constraints*: `x.base() != y.base()` is well-formed and convertible to `bool`.

4 *Returns*: `x.base() != y.base()`.

```
template<class Iterator1, class Iterator2>
  constexpr bool operator<(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);
```

5 *Constraints*: `x.base() > y.base()` is well-formed and convertible to `bool`.

6 *Returns*: `x.base() > y.base()`.

```
template<class Iterator1, class Iterator2>
  constexpr bool operator>(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);
```

7 *Constraints*: `x.base() < y.base()` is well-formed and convertible to `bool`.

8 *Returns*: `x.base() < y.base()`.

```
template<class Iterator1, class Iterator2>
  constexpr bool operator<=(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);
```

9 *Constraints*: `x.base() >= y.base()` is well-formed and convertible to `bool`.

10 *Returns*: `x.base() >= y.base()`.

```
template<class Iterator1, class Iterator2>
  constexpr bool operator>=(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);
```

11 *Constraints*: `x.base() <= y.base()` is well-formed and convertible to `bool`.

12 *Returns*: `x.base() <= y.base()`.

```
template<class Iterator1, three_way_comparable_with<Iterator1> Iterator2>
  constexpr compare_three_way_result_t<Iterator1, Iterator2>
    operator<=>(const reverse_iterator<Iterator1>& x,
                const reverse_iterator<Iterator2>& y);
```

13 *Returns*: `y.base() <=> x.base()`.

14 [*Note 1*: The argument order in the *Returns*: element is reversed because this is a reverse iterator. — *end note*]

24.5.1.9 Non-member functions [reverse.iter.nonmember]

```
template<class Iterator1, class Iterator2>
  constexpr auto operator-(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y) -> decltype(y.base() - x.base());
```

1 *Returns*: `y.base() - x.base()`.

```
template<class Iterator>
  constexpr reverse_iterator<Iterator> operator+(
    iter_difference_t<Iterator> n,
    const reverse_iterator<Iterator>& x);
```

2 *Returns*: `reverse_iterator<Iterator>(x.base() - n)`.

```
friend constexpr iter_rvalue_reference_t<Iterator>
  iter_move(const reverse_iterator& i) noexcept(see below);
```

3 *Effects*: Equivalent to:

```
auto tmp = i.base();
return ranges::iter_move(--tmp);
```

4 *Remarks*: The exception specification is equivalent to:

```
is_nothrow_copy_constructible_v<Iterator> &&
noexcept(ranges::iter_move(--declval<Iterator&>()))
```

```
template<indirectly_swappable<Iterator> Iterator2>
  friend constexpr void
    iter_swap(const reverse_iterator& x,
              const reverse_iterator<Iterator2>& y) noexcept(see below);
```

5 *Effects*: Equivalent to:

```
    auto xtmp = x.base();
    auto ytmp = y.base();
    ranges::iter_swap(--xtmp, --ytmp);
```

6 *Remarks*: The exception specification is equivalent to:

```
    is_nothrow_copy_constructible_v<Iterator> &&
    is_nothrow_copy_constructible_v<Iterator2> &&
    noexcept(ranges::iter_swap(--declval<Iterator&>(), --declval<Iterator2&>()))
```

```
template<class Iterator>
  constexpr reverse_iterator<Iterator> make_reverse_iterator(Iterator i);
```

7 *Returns*: `reverse_iterator<Iterator>(i)`.

24.5.2 Insert iterators [insert.iterators]

24.5.2.1 General [insert.iterators.general]

1 To make it possible to deal with insertion in the same way as writing into an array, a special kind of iterator adaptors, called *insert iterators*, are provided in the library. With regular iterator classes,

```
while (first != last) *result++ = *first++;
```

causes a range [`first`, `last`) to be copied into a range starting with result. The same code with `result` being an insert iterator will insert corresponding elements into the container. This device allows all of the copying algorithms in the library to work in the *insert mode* instead of the *regular overwrite* mode.

2 An insert iterator is constructed from a container and possibly one of its iterators pointing to where insertion takes place if it is neither at the beginning nor at the end of the container. Insert iterators meet the requirements of output iterators. `operator*` returns the insert iterator itself. The assignment `operator=(const T& x)` is defined on insert iterators to allow writing into them, it inserts `x` right before where the insert iterator is pointing. In other words, an insert iterator is like a cursor pointing into the container where the insertion takes place. `back_insert_iterator` inserts elements at the end of a container, `front_insert_iterator` inserts elements at the beginning of a container, and `insert_iterator` inserts elements where the iterator points to in a container. `back_inserter`, `front_inserter`, and `inserter` are three functions making the insert iterators out of a container.

24.5.2.2 Class template `back_insert_iterator` [back.insert.iterator]

24.5.2.2.1 General [back.insert.iter.general]

```
namespace std {
  template<class Container>
  class back_insert_iterator {
  protected:
    Container* container;

  public:
    using iterator_category = output_iterator_tag;
    using value_type        = void;
    using difference_type   = ptrdiff_t;
    using pointer           = void;
    using reference         = void;
    using container_type    = Container;

    constexpr explicit back_insert_iterator(Container& x);
    constexpr back_insert_iterator& operator=(const typename Container::value_type& value);
    constexpr back_insert_iterator& operator=(typename Container::value_type&& value);

    constexpr back_insert_iterator& operator*();
    constexpr back_insert_iterator& operator++();
    constexpr back_insert_iterator  operator++(int);
  };
}
```

24.5.2.2.2 Operations [back.insert.iter.ops]

```
constexpr explicit back_insert_iterator(Container& x);
```

1 *Effects*: Initializes `container` with `addressof(x)`.

```
constexpr back_insert_iterator& operator=(const typename Container::value_type& value);
```

2 *Effects*: As if by: `container->push_back(value);`

3 *Returns*: `*this`.

```
constexpr back_insert_iterator& operator=(typename Container::value_type&& value);
```

4 *Effects*: As if by: `container->push_back(std::move(value));`

5 *Returns*: `*this`.

```
constexpr back_insert_iterator& operator*();
```

6 *Returns*: `*this`.

```
constexpr back_insert_iterator& operator++();
constexpr back_insert_iterator  operator++(int);
```

7 *Returns*: `*this`.

24.5.2.2.3 `back_inserter` [back.inserter]

```
template<class Container>
  constexpr back_insert_iterator<Container> back_inserter(Container& x);
```

1 *Returns*: `back_insert_iterator<Container>(x)`.

24.5.2.3 Class template `front_insert_iterator` [front.insert.iterator]

24.5.2.3.1 General [front.insert.iter.general]

```
namespace std {
  template<class Container>
  class front_insert_iterator {
  protected:
    Container* container;

  public:
    using iterator_category = output_iterator_tag;
    using value_type        = void;
    using difference_type   = ptrdiff_t;
    using pointer           = void;
    using reference         = void;
    using container_type    = Container;

    constexpr explicit front_insert_iterator(Container& x);
    constexpr front_insert_iterator& operator=(const typename Container::value_type& value);
    constexpr front_insert_iterator& operator=(typename Container::value_type&& value);

    constexpr front_insert_iterator& operator*();
    constexpr front_insert_iterator& operator++();
    constexpr front_insert_iterator  operator++(int);
  };
}
```

24.5.2.3.2 Operations [front.insert.iter.ops]

```
constexpr explicit front_insert_iterator(Container& x);
```

1 *Effects*: Initializes `container` with `addressof(x)`.

```
constexpr front_insert_iterator& operator=(const typename Container::value_type& value);
```

2 *Effects*: As if by: `container->push_front(value);`

3 *Returns*: `*this`.

```
constexpr front_insert_iterator& operator=(typename Container::value_type&& value);
```

4 *Effects*: As if by: `container->push_front(std::move(value));`

5 *Returns*: `*this`.

```
constexpr front_insert_iterator& operator*();
```

6 *Returns*: `*this`.

```
constexpr front_insert_iterator& operator++();
constexpr front_insert_iterator  operator++(int);
```

7 *Returns*: `*this`.

24.5.2.3.3 `front_inserter` [front.inserter]

```
template<class Container>
  constexpr front_insert_iterator<Container> front_inserter(Container& x);
```

1 *Returns*: `front_insert_iterator<Container>(x)`.

24.5.2.4 Class template `insert_iterator` [insert.iterator]

24.5.2.4.1 General [insert.iter.general]

```
namespace std {
  template<class Container>
  class insert_iterator {
  protected:
    Container* container;
    ranges::iterator_t<Container> iter;

  public:
    using iterator_category = output_iterator_tag;
    using value_type        = void;
    using difference_type   = ptrdiff_t;
    using pointer           = void;
    using reference         = void;
    using container_type    = Container;

    constexpr insert_iterator(Container& x, ranges::iterator_t<Container> i);
    constexpr insert_iterator& operator=(const typename Container::value_type& value);
    constexpr insert_iterator& operator=(typename Container::value_type&& value);

    constexpr insert_iterator& operator*();
    constexpr insert_iterator& operator++();
    constexpr insert_iterator& operator++(int);
  };
}
```

24.5.2.4.2 Operations [insert.iter.ops]

```
constexpr insert_iterator(Container& x, ranges::iterator_t<Container> i);
```

1 *Effects*: Initializes `container` with `addressof(x)` and `iter` with `i`.

```
constexpr insert_iterator& operator=(const typename Container::value_type& value);
```

2 *Effects*: As if by:

```
iter = container->insert(iter, value);
++iter;
```

3 *Returns*: `*this`.

```
constexpr insert_iterator& operator=(typename Container::value_type&& value);
```

4 *Effects*: As if by:

```
iter = container->insert(iter, std::move(value));
++iter;
```

5 *Returns*: `*this`.

```
constexpr insert_iterator& operator*();
```

6 *Returns*: `*this`.

```
constexpr insert_iterator& operator++();
constexpr insert_iterator& operator++(int);
```

7 *Returns*: `*this`.

24.5.2.4.3 `inserter` [inserter]

```
template<class Container>
  constexpr insert_iterator<Container>
    inserter(Container& x, ranges::iterator_t<Container> i);
```

1 *Returns*: `insert_iterator<Container>(x, i)`.

24.5.3 Constant iterators and sentinels [const.iterators]

24.5.3.1 General [const.iterators.general]

1 Class template `basic_const_iterator` is an iterator adaptor with the same behavior as the underlying iterator except that its indirection operator implicitly converts the value returned by the underlying iterator's indirection operator to a type such that the adapted iterator is a constant iterator (24.3). Some generic algorithms can be called with constant iterators to avoid mutation.

2 Specializations of `basic_const_iterator` are constant iterators.

24.5.3.2 Alias templates [const.iterators.alias]

```
template<indirectly_readable It>
  using iter_const_reference_t =
    common_reference_t<const iter_value_t<It>&&, iter_reference_t<It>>;

template<class It>
  concept constant-iterator =                                    // exposition only
    input_iterator<It> && same_as<iter_const_reference_t<It>, iter_reference_t<It>>;

template<input_iterator I>
  using const_iterator = see below;
```

1 *Result*: If `I` models *constant-iterator*, `I`. Otherwise, `basic_const_iterator<I>`.

```
template<semiregular S>
  using const_sentinel = see below;
```

2 *Result*: If `S` models `input_iterator`, `const_iterator<S>`. Otherwise, `S`.

24.5.3.3 Class template `basic_const_iterator` [const.iterators.iterator]

```
namespace std {
  template<class I>
    concept not-a-const-iterator = see below;                    // exposition only

  template<indirectly_readable I>
    using iter-const-rvalue-reference-t =                        // exposition only
      common_reference_t<const iter_value_t<I>&&, iter_rvalue_reference_t<I>>;

  template<input_iterator Iterator>
  class basic_const_iterator {
    Iterator current_ = Iterator();                              // exposition only
    using reference = iter_const_reference_t<Iterator>;          // exposition only
    using rvalue-reference =                                     // exposition only
      iter-const-rvalue-reference-t<Iterator>;

  public:
    using iterator_type = Iterator;
    using iterator_concept = see below;
    using iterator_category = see below;  // not always present
    using value_type = iter_value_t<Iterator>;
```

```
using difference_type = iter_difference_t<Iterator>;

basic_const_iterator() requires default_initializable<Iterator> = default;
constexpr basic_const_iterator(Iterator current);
template<convertible_to<Iterator> U>
  constexpr basic_const_iterator(basic_const_iterator<U> current);
template<different-from<basic_const_iterator> T>
  requires convertible_to<T, Iterator>
  constexpr basic_const_iterator(T&& current);

constexpr const Iterator& base() const & noexcept;
constexpr Iterator base() &&;

constexpr reference operator*() const;
constexpr const auto* operator->() const
  requires is_lvalue_reference_v<iter_reference_t<Iterator>> &&
           same_as<remove_cvref_t<iter_reference_t<Iterator>>, value_type>;

constexpr basic_const_iterator& operator++();
constexpr void operator++(int);
constexpr basic_const_iterator operator++(int) requires forward_iterator<Iterator>;

constexpr basic_const_iterator& operator--() requires bidirectional_iterator<Iterator>;
constexpr basic_const_iterator operator--(int) requires bidirectional_iterator<Iterator>;

constexpr basic_const_iterator& operator+=(difference_type n)
  requires random_access_iterator<Iterator>;
constexpr basic_const_iterator& operator-=(difference_type n)

      }
  };
}
```

1 Given some type `I`, the concept *not-a-const-iterator* is defined as `false` if `I` is a specialization of `basic_const_iterator` and `true` otherwise.

24.5.3.4 Member types [const.iterators.types]

1 `basic_const_iterator<Iterator>::iterator_concept` is defined as follows:

(1.1) — If `Iterator` models `contiguous_iterator`, then `iterator_concept` denotes `contiguous_iterator_tag`.

(1.2) — Otherwise, if `Iterator` models `random_access_iterator`, then `iterator_concept` denotes `random_access_iterator_tag`.

(1.3) — Otherwise, if `Iterator` models `bidirectional_iterator`, then `iterator_concept` denotes `bidirectional_iterator_tag`.

(1.4) — Otherwise, if `Iterator` models `forward_iterator`, then `iterator_concept` denotes `forward_iterator_tag`.

(1.5) — Otherwise, `iterator_concept` denotes `input_iterator_tag`.

2 The member *typedef-name* `iterator_category` is declared if and only if `Iterator` models `forward_iterator`. In that case, `basic_const_iterator<Iterator>::iterator_category` denotes the type `iterator_traits<Iterator>::iterator_category`.

24.5.3.5 Operations [const.iterators.ops]

```
constexpr basic_const_iterator(Iterator current);
```

1 *Effects*: Initializes *current_* with `std::move(current)`.

```
template<convertible_to<Iterator> U>
  constexpr basic_const_iterator(basic_const_iterator<U> current);
```

2 *Effects*: Initializes *current_* with `std::move(current.`*current_*`)`.

```
template<different-from<basic_const_iterator> T>
  requires convertible_to<T, Iterator>
  constexpr basic_const_iterator(T&& current);
```

3 *Effects*: Initializes *current_* with `std::forward<T>(current)`.

```
constexpr const Iterator& base() const & noexcept;
```

4 *Effects*: Equivalent to: `return` *current_*`;`

```
constexpr Iterator base() &&;
```

5 *Effects*: Equivalent to: `return std::move(`*current_*`);`

```
constexpr reference operator*() const;
```

6 *Effects*: Equivalent to: `return static_cast<`*reference*`>(*`*current_*`);`

```
constexpr const auto* operator->() const
  requires is_lvalue_reference_v<iter_reference_t<Iterator>> &&
           same_as<remove_cvref_t<iter_reference_t<Iterator>>, value_type>;
```

7 *Returns*: If `Iterator` models `contiguous_iterator`, `to_address(`*current_*`)`; otherwise, `addressof(*`*current_*`)`.

```
constexpr basic_const_iterator& operator++();
```

8 *Effects*: Equivalent to:

```
++current_;
return *this;
```

```
constexpr void operator++(int);
```

9 *Effects*: Equivalent to: `++`*current_*`;`

```
constexpr basic_const_iterator operator++(int) requires forward_iterator<Iterator>;
```

10 *Effects*: Equivalent to:

```
auto tmp = *this;
++*this;
return tmp;
```

```
constexpr basic_const_iterator& operator--() requires bidirectional_iterator<Iterator>;
```

11 *Effects*: Equivalent to:

```
--current_;
return *this;
```

```
constexpr basic_const_iterator operator--(int) requires bidirectional_iterator<Iterator>;
```

12 *Effects*: Equivalent to:

```
auto tmp = *this;
--*this;
return tmp;
```

```
constexpr basic_const_iterator& operator+=(difference_type n)
  requires random_access_iterator<Iterator>;
constexpr basic_const_iterator& operator-=(difference_type n)
  requires random_access_iterator<Iterator>;
```

13 Let *op* be the operator.

14 *Effects*: Equivalent to:

```
current_ op n;
return *this;
```

```
constexpr reference operator[](difference_type n) const requires random_access_iterator<Iterator>
```

15 *Effects*: Equivalent to: `return static_cast<reference>(current_[n]);`

```
template<sentinel_for<Iterator> S>
  constexpr bool operator==(const S& s) const;
```

16 *Effects*: Equivalent to: `return current_ == s;`

```
template<not-a-const-iterator CI>
  requires constant-iterator<CI> && convertible_to<Iterator const&, CI>
constexpr operator CI() const &;
```

17 *Returns*: `current_`.

```
template<not-a-const-iterator CI>
  requires constant-iterator<CI> && convertible_to<Iterator, CI>
constexpr operator CI() &&;
```

18 *Returns*: `std::move(current_)`.

```
constexpr bool operator<(const basic_const_iterator& y) const
  requires random_access_iterator<Iterator>;
constexpr bool operator>(const basic_const_iterator& y) const
  requires random_access_iterator<Iterator>;
constexpr bool operator<=(const basic_const_iterator& y) const
  requires random_access_iterator<Iterator>;
constexpr bool operator>=(const basic_const_iterator& y) const
  requires random_access_iterator<Iterator>;
constexpr auto operator<=>(const basic_const_iterator& y) const
  requires random_access_iterator<Iterator> && three_way_comparable<Iterator>;
```

19 Let *op* be the operator.

20 *Effects*: Equivalent to: `return current_ op y.current_;`

```
template<different-from<basic_const_iterator> I>
  constexpr bool operator<(const I& y) const
    requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
template<different-from<basic_const_iterator> I>
  constexpr bool operator>(const I& y) const
    requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
template<different-from<basic_const_iterator> I>
  constexpr bool operator<=(const I& y) const
    requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
template<different-from<basic_const_iterator> I>
  constexpr bool operator>=(const I& y) const
    requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
template<different-from<basic_const_iterator> I>
  constexpr auto operator<=>(const I& y) const
    requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I> &&
             three_way_comparable_with<Iterator, I>;
```

21 Let *op* be the operator.

22 *Effects*: Equivalent to: `return current_ op y;`

```
template<not-a-const-iterator I>
  friend constexpr bool operator<(const I& x, const basic_const_iterator& y)
    requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
template<not-a-const-iterator I>
  friend constexpr bool operator>(const I& x, const basic_const_iterator& y)
    requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
```

```
template<not-a-const-iterator I>
  friend constexpr bool operator<=(const I& x, const basic_const_iterator& y)
    requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
template<not-a-const-iterator I>
  friend constexpr bool operator>=(const I& x, const basic_const_iterator& y)
    requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
```

23 Let *op* be the operator.

24 *Effects*: Equivalent to: `return x op y.current_;`

```
friend constexpr basic_const_iterator operator+(const basic_const_iterator& i, difference_type n)
  requires random_access_iterator<Iterator>;
friend constexpr basic_const_iterator operator+(difference_type n, const basic_const_iterator& i)
  requires random_access_iterator<Iterator>;
```

25 *Effects*: Equivalent to: `return basic_const_iterator(i.current_ + n);`

```
friend constexpr basic_const_iterator operator-(const basic_const_iterator& i, difference_type n)
  requires random_access_iterator<Iterator>;
```

26 *Effects*: Equivalent to: `return basic_const_iterator(i.current_ - n);`

```
template<sized_sentinel_for<Iterator> S>
  constexpr difference_type operator-(const S& y) const;
```

27 *Effects*: Equivalent to: `return current_ - y;`

```
template<not-a-const-iterator S>
  requires sized_sentinel_for<S, Iterator>
  friend constexpr difference_type operator-(const S& x, const basic_const_iterator& y);
```

28 *Effects*: Equivalent to: `return x - y.current_;`

24.5.4 Move iterators and sentinels [move.iterators]

24.5.4.1 General [move.iterators.general]

1 Class template `move_iterator` is an iterator adaptor with the same behavior as the underlying iterator except that its indirection operator implicitly converts the value returned by the underlying iterator's indirection operator to an rvalue. Some generic algorithms can be called with move iterators to replace copying with moving.

2 [*Example 1*:

```
list<string> s;
// populate the list s
vector<string> v1(s.begin(), s.end());          // copies strings into v1
vector<string> v2(make_move_iterator(s.begin()),
                  make_move_iterator(s.end())); // moves strings into v2
```

— *end example*]

24.5.4.2 Class template `move_iterator` [move.iterator]

```
namespace std {
  template<class Iterator>
  class move_iterator {
  public:
    using iterator_type     = Iterator;
    using iterator_concept  = see below;
    using iterator_category = see below;                    // not always present
    using value_type        = iter_value_t<Iterator>;
    using difference_type   = iter_difference_t<Iterator>;
    using pointer           = Iterator;
    using reference         = iter_rvalue_reference_t<Iterator>;

    constexpr move_iterator();
    constexpr explicit move_iterator(Iterator i);
    template<class U> constexpr move_iterator(const move_iterator<U>& u);
    template<class U> constexpr move_iterator& operator=(const move_iterator<U>& u);
```

```
    constexpr const Iterator& base() const & noexcept;
    constexpr Iterator base() &&;
    constexpr reference operator*() const;

    constexpr move_iterator& operator++();
    constexpr auto operator++(int);
    constexpr move_iterator& operator--();
    constexpr move_iterator operator--(int);

    constexpr move_iterator operator+(difference_type n) const;
    constexpr move_iterator& operator+=(difference_type n);
    constexpr move_iterator operator-(difference_type n) const;
    constexpr move_iterator& operator-=(difference_type n);
    constexpr reference operator[](difference_type n) const;

    template<sentinel_for<Iterator> S>
      friend constexpr bool
        operator==(const move_iterator& x, const move_sentinel<S>& y);
    template<sized_sentinel_for<Iterator> S>
      friend constexpr iter_difference_t<Iterator>
        operator-(const move_sentinel<S>& x, const move_iterator& y);
    template<sized_sentinel_for<Iterator> S>
      friend constexpr iter_difference_t<Iterator>
        operator-(const move_iterator& x, const move_sentinel<S>& y);
    friend constexpr iter_rvalue_reference_t<Iterator>
      iter_move(const move_iterator& i)
        noexcept(noexcept(ranges::iter_move(i.current)));
    template<indirectly_swappable<Iterator> Iterator2>
      friend constexpr void
        iter_swap(const move_iterator& x, const move_iterator<Iterator2>& y)
          noexcept(noexcept(ranges::iter_swap(x.current, y.current)));

  private:
    Iterator current;    // exposition only
  };
}
```

1 The member *typedef-name* `iterator_concept` is defined as follows:

(1.1) — If `Iterator` models `random_access_iterator`, then `iterator_concept` denotes `random_access_iterator_tag`.

(1.2) — Otherwise, if `Iterator` models `bidirectional_iterator`, then `iterator_concept` denotes `bidirectional_iterator_tag`.

(1.3) — Otherwise, if `Iterator` models `forward_iterator`, then `iterator_concept` denotes `forward_iterator_tag`.

(1.4) — Otherwise, `iterator_concept` denotes `input_iterator_tag`.

2 The member *typedef-name* `iterator_category` is declared if and only if the *qualified-id* `iterator_traits<Iterator>::iterator_category` is valid and denotes a type. In that case, `iterator_category` denotes

(2.1) — `random_access_iterator_tag` if the type `iterator_traits<Iterator>::iterator_category` models `derived_from<random_access_iterator_tag>`, and

(2.2) — `iterator_traits<Iterator>::iterator_category` otherwise.

24.5.4.3 Requirements [move.iter.requirements]

1 The template parameter `Iterator` shall either meet the *Cpp17InputIterator* requirements (24.3.5.3) or model `input_iterator` (24.3.4.9). Additionally, if any of the bidirectional traversal functions are instantiated, the template parameter shall either meet the *Cpp17BidirectionalIterator* requirements (24.3.5.6) or model `bidirectional_iterator` (24.3.4.12). If any of the random access traversal functions are instantiated, the template parameter shall either meet the *Cpp17RandomAccessIterator* requirements (24.3.5.7) or model `random_access_iterator` (24.3.4.13).

24.5.4.4 Construction and assignment [move.iter.cons]

```
constexpr move_iterator();
```

1 *Effects*: Value-initializes `current`.

```
constexpr explicit move_iterator(Iterator i);
```

2 *Effects*: Initializes `current` with `std::move(i)`.

```
template<class U> constexpr move_iterator(const move_iterator<U>& u);
```

3 *Constraints*: `is_same_v<U, Iterator>` is `false` and `const U&` models `convertible_to<Iterator>`.

4 *Effects*: Initializes `current` with `u.current`.

```
template<class U> constexpr move_iterator& operator=(const move_iterator<U>& u);
```

5 *Constraints*: `is_same_v<U, Iterator>` is `false`, `const U&` models `convertible_to<Iterator>`, and `assignable_from<Iterator&, const U&>` is modeled.

6 *Effects*: Assigns `u.current` to `current`.

7 *Returns*: `*this`.

24.5.4.5 Conversion [move.iter.op.conv]

```
constexpr const Iterator& base() const & noexcept;
```

1 *Returns*: `current`.

```
constexpr Iterator base() &&;
```

2 *Returns*: `std::move(current)`.

24.5.4.6 Element access [move.iter.elem]

```
constexpr reference operator*() const;
```

1 *Effects*: Equivalent to: `return ranges::iter_move(current);`

```
constexpr reference operator[](difference_type n) const;
```

2 *Effects*: Equivalent to: `return ranges::iter_move(current + n);`

24.5.4.7 Navigation [move.iter.nav]

```
constexpr move_iterator& operator++();
```

1 *Effects*: As if by `++current`.

2 *Returns*: `*this`.

```
constexpr auto operator++(int);
```

3 *Effects*: If `Iterator` models `forward_iterator`, equivalent to:

```
move_iterator tmp = *this;
++current;
return tmp;
```

Otherwise, equivalent to `++current`.

```
constexpr move_iterator& operator--();
```

4 *Effects*: As if by `--current`.

5 *Returns*: `*this`.

```
constexpr move_iterator operator--(int);
```

6 *Effects*: As if by:

```
move_iterator tmp = *this;
--current;
return tmp;
```

```
constexpr move_iterator operator+(difference_type n) const;
```

7 *Returns*: `move_iterator(current + n)`.

```
constexpr move_iterator& operator+=(difference_type n);
```

8 *Effects*: As if by: `current += n;`

9 *Returns*: `*this`.

```
constexpr move_iterator operator-(difference_type n) const;
```

10 *Returns*: `move_iterator(current - n)`.

```
constexpr move_iterator& operator-=(difference_type n);
```

11 *Effects*: As if by: `current -= n;`

12 *Returns*: `*this`.

24.5.4.8 Comparisons [move.iter.op.comp]

```
template<class Iterator1, class Iterator2>
  constexpr bool operator==(const move_iterator<Iterator1>& x,
                            const move_iterator<Iterator2>& y);
template<sentinel_for<Iterator> S>
  friend constexpr bool operator==(const move_iterator& x,
                                   const move_sentinel<S>& y);
```

1 *Constraints*: `x.base() == y.base()` is well-formed and convertible to `bool`.

2 *Returns*: `x.base() == y.base()`.

```
template<class Iterator1, class Iterator2>
constexpr bool operator<(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
```

3 *Constraints*: `x.base() < y.base()` is well-formed and convertible to `bool`.

4 *Returns*: `x.base() < y.base()`.

```
template<class Iterator1, class Iterator2>
constexpr bool operator>(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
```

5 *Constraints*: `y.base() < x.base()` is well-formed and convertible to `bool`.

6 *Returns*: `y < x`.

```
template<class Iterator1, class Iterator2>
constexpr bool operator<=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
```

7 *Constraints*: `y.base() < x.base()` is well-formed and convertible to `bool`.

8 *Returns*: `!(y < x)`.

```
template<class Iterator1, class Iterator2>
constexpr bool operator>=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
```

9 *Constraints*: `x.base() < y.base()` is well-formed and convertible to `bool`.

10 *Returns*: `!(x < y)`.

```
template<class Iterator1, three_way_comparable_with<Iterator1> Iterator2>
  constexpr compare_three_way_result_t<Iterator1, Iterator2>
    operator<=>(const move_iterator<Iterator1>& x,
                const move_iterator<Iterator2>& y);
```

11 *Returns*: `x.base() <=> y.base()`.

24.5.4.9 Non-member functions [move.iter.nonmember]

```
template<class Iterator1, class Iterator2>
  constexpr auto operator-(
    const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y)
      -> decltype(x.base() - y.base());
```

```
template<sized_sentinel_for<Iterator> S>
  friend constexpr iter_difference_t<Iterator>
    operator-(const move_sentinel<S>& x, const move_iterator& y);
template<sized_sentinel_for<Iterator> S>
  friend constexpr iter_difference_t<Iterator>
    operator-(const move_iterator& x, const move_sentinel<S>& y);
```

1 *Returns*: `x.base() - y.base()`.

```
template<class Iterator>
  constexpr move_iterator<Iterator>
    operator+(iter_difference_t<Iterator> n, const move_iterator<Iterator>& x);
```

2 *Constraints*: `x.base() + n` is well-formed and has type `Iterator`.

3 *Returns*: `x + n`.

```
friend constexpr iter_rvalue_reference_t<Iterator>
  iter_move(const move_iterator& i)
    noexcept(noexcept(ranges::iter_move(i.current)));
```

4 *Effects*: Equivalent to: `return ranges::iter_move(i.current);`

```
template<indirectly_swappable<Iterator> Iterator2>
  friend constexpr void
    iter_swap(const move_iterator& x, const move_iterator<Iterator2>& y)
      noexcept(noexcept(ranges::iter_swap(x.current, y.current)));
```

5 *Effects*: Equivalent to: `ranges::iter_swap(x.current, y.current)`.

```
template<class Iterator>
  constexpr move_iterator<Iterator> make_move_iterator(Iterator i);
```

6 *Returns*: `move_iterator<Iterator>(std::move(i))`.

24.5.4.10 Class template `move_sentinel` [move.sentinel]

1 Class template `move_sentinel` is a sentinel adaptor useful for denoting ranges together with `move_iterator`. When an input iterator type `I` and sentinel type `S` model `sentinel_for<S, I>`, `move_sentinel<S>` and `move_iterator<I>` model `sentinel_for<move_sentinel<S>, move_iterator<I>>` as well.

2 [*Example 1*: A `move_if` algorithm is easily implemented with `copy_if` using `move_iterator` and `move_sentinel`:

```
template<input_iterator I, sentinel_for<I> S, weakly_incrementable O,
         indirect_unary_predicate<I> Pred>
  requires indirectly_movable<I, O>
void move_if(I first, S last, O out, Pred pred) {
  ranges::copy_if(move_iterator<I>{std::move(first)}, move_sentinel<S>{last},
                  std::move(out), pred);
}
```

— *end example*]

```
namespace std {
  template<semiregular S>
  class move_sentinel {
  public:
    constexpr move_sentinel();
    constexpr explicit move_sentinel(S s);
    template<class S2>
      requires convertible_to<const S2&, S>
        constexpr move_sentinel(const move_sentinel<S2>& s);
    template<class S2>
      requires assignable_from<S&, const S2&>
        constexpr move_sentinel& operator=(const move_sentinel<S2>& s);

    constexpr S base() const;

  private:
    S last;      // exposition only
```

```
  };
}
```

24.5.4.11 Operations [move.sent.ops]

```
constexpr move_sentinel();
```

1 *Effects*: Value-initializes `last`. If `is_trivially_default_constructible_v<S>` is `true`, then this constructor is a `constexpr` constructor.

```
constexpr explicit move_sentinel(S s);
```

2 *Effects*: Initializes `last` with `std::move(s)`.

```
template<class S2>
  requires convertible_to<const S2&, S>
    constexpr move_sentinel(const move_sentinel<S2>& s);
```

3 *Effects*: Initializes `last` with `s.last`.

```
template<class S2>
  requires assignable_from<S&, const S2&>
    constexpr move_sentinel& operator=(const move_sentinel<S2>& s);
```

4 *Effects*: Equivalent to: `last = s.last; return *this;`

```
constexpr S base() const;
```

5 *Returns*: `last`.

24.5.5 Common iterators [iterators.common]

24.5.5.1 Class template `common_iterator` [common.iterator]

1 Class template `common_iterator` is an iterator/sentinel adaptor that is capable of representing a non-common range of elements (where the types of the iterator and sentinel differ) as a common range (where they are the same). It does this by holding either an iterator or a sentinel, and implementing the equality comparison operators appropriately.

2 [*Note 1*: The `common_iterator` type is useful for interfacing with legacy code that expects the begin and end of a range to have the same type. — *end note*]

3 [*Example 1*:

```
template<class ForwardIterator>
void fun(ForwardIterator begin, ForwardIterator end);

list<int> s;
// populate the list s
using CI = common_iterator<counted_iterator<list<int>::iterator>, default_sentinel_t>;
// call fun on a range of 10 ints
fun(CI(counted_iterator(s.begin(), 10)), CI(default_sentinel));
```

— *end example*]

```
namespace std {
  template<input_or_output_iterator I, sentinel_for<I> S>
    requires (!same_as<I, S> && copyable<I>)
  class common_iterator {
  public:
    constexpr common_iterator() requires default_initializable<I> = default;
    constexpr common_iterator(I i);
    constexpr common_iterator(S s);
    template<class I2, class S2>
      requires convertible_to<const I2&, I> && convertible_to<const S2&, S>
        constexpr common_iterator(const common_iterator<I2, S2>& x);

    template<class I2, class S2>
      requires convertible_to<const I2&, I> && convertible_to<const S2&, S> &&
               assignable_from<I&, const I2&> && assignable_from<S&, const S2&>
        constexpr common_iterator& operator=(const common_iterator<I2, S2>& x);
```

```
    constexpr decltype(auto) operator*();
    constexpr decltype(auto) operator*() const
      requires dereferenceable<const I>;
    constexpr auto operator->() const
      requires see below;

    constexpr common_iterator& operator++();
    constexpr decltype(auto) operator++(int);

    template<class I2, sentinel_for<I> S2>
      requires sentinel_for<S, I2>
    friend constexpr bool operator==(
      const common_iterator& x, const common_iterator<I2, S2>& y);
    template<class I2, sentinel_for<I> S2>
      requires sentinel_for<S, I2> && equality_comparable_with<I, I2>
    friend constexpr bool operator==(
      const common_iterator& x, const common_iterator<I2, S2>& y);

    template<sized_sentinel_for<I> I2, sized_sentinel_for<I> S2>
      requires sized_sentinel_for<S, I2>
    friend constexpr iter_difference_t<I2> operator-(
      const common_iterator& x, const common_iterator<I2, S2>& y);

    friend constexpr decltype(auto) iter_move(const common_iterator& i)
      noexcept(noexcept(ranges::iter_move(declval<const I&>())))
        requires input_iterator<I>;
    template<indirectly_swappable<I> I2, class S2>
      friend constexpr void iter_swap(const common_iterator& x, const common_iterator<I2, S2>& y)
        noexcept(noexcept(ranges::iter_swap(declval<const I&>(), declval<const I2&>())));

  private:
    variant<I, S> v_;    // exposition only
  };

  template<class I, class S>
  struct incrementable_traits<common_iterator<I, S>> {
    using difference_type = iter_difference_t<I>;
  };

  template<input_iterator I, class S>
  struct iterator_traits<common_iterator<I, S>> {
    using iterator_concept = see below;
    using iterator_category = see below;  // not always present
    using value_type = iter_value_t<I>;
    using difference_type = iter_difference_t<I>;
    using pointer = see below;
    using reference = iter_reference_t<I>;
  };
}
```

24.5.5.2 Associated types [common.iter.types]

1 The nested *typedef-name* `iterator_category` of the specialization of `iterator_traits` for `common_iterator<I, S>` is declared if and only if `iter_difference_t<I>` is an integral type. In that case, `iterator_category` denotes `forward_iterator_tag` if the *qualified-id* `iterator_traits<I>::iterator_category` is valid and denotes a type that models `derived_from<forward_iterator_tag>`; otherwise it denotes `input_iterator_tag`.

2 The remaining nested *typedef-name*s of the specialization of `iterator_traits` for `common_iterator<I, S>` are defined as follows:

(2.1) — `iterator_concept` denotes `forward_iterator_tag` if `I` models `forward_iterator`; otherwise it denotes `input_iterator_tag`.

(2.2) — Let `a` denote an lvalue of type `const common_iterator<I, S>`. If the expression `a.operator->()` is well-formed, then `pointer` denotes `decltype(a.operator->())`. Otherwise, `pointer` denotes `void`.

24.5.5.3 Constructors and conversions [common.iter.const]

```
constexpr common_iterator(I i);
```

1 *Effects*: Initializes `v_` as if by `v_{in_place_type<I>, std::move(i)}`.

```
constexpr common_iterator(S s);
```

2 *Effects*: Initializes `v_` as if by `v_{in_place_type<S>, std::move(s)}`.

```
template<class I2, class S2>
  requires convertible_to<const I2&, I> && convertible_to<const S2&, S>
    constexpr common_iterator(const common_iterator<I2, S2>& x);
```

3 *Hardened preconditions*: `x.v_.valueless_by_exception()` is `false`.

4 *Effects*: Initializes `v_` as if by `v_{in_place_index<`*i*`>, get<`*i*`>(x.v_)}`, where *i* is `x.v_.index()`.

```
template<class I2, class S2>
  requires convertible_to<const I2&, I> && convertible_to<const S2&, S> &&
           assignable_from<I&, const I2&> && assignable_from<S&, const S2&>
    constexpr common_iterator& operator=(const common_iterator<I2, S2>& x);
```

5 *Hardened preconditions*: `x.v_.valueless_by_exception()` is `false`.

6 *Effects*: Equivalent to:

(6.1) — If `v_.index() == x.v_.index()`, then `get<`*i*`>(v_) = get<`*i*`>(x.v_)`.

(6.2) — Otherwise, `v_.emplace<`*i*`>(get<`*i*`>(x.v_))`.

where *i* is `x.v_.index()`.

7 *Returns*: `*this`.

24.5.5.4 Accessors [common.iter.access]

```
constexpr decltype(auto) operator*();
constexpr decltype(auto) operator*() const
  requires dereferenceable<const I>;
```

1 *Hardened preconditions*: `holds_alternative<I>(v_)` is `true`.

2 *Effects*: Equivalent to: `return *get<I>(v_);`

```
constexpr auto operator->() const
  requires see below;
```

3 The expression in the *requires-clause* is equivalent to:

```
indirectly_readable<const I> &&
(requires(const I& i) { i.operator->(); } ||
 is_reference_v<iter_reference_t<I>> ||
 constructible_from<iter_value_t<I>, iter_reference_t<I>>)
```

4 *Hardened preconditions*: `holds_alternative<I>(v_)` is `true`.

5 *Effects*:

(5.1) — If `I` is a pointer type or if the expression `get<I>(v_).operator->()` is well-formed, equivalent to: `return get<I>(v_);`

(5.2) — Otherwise, if `iter_reference_t<I>` is a reference type, equivalent to:

```
auto&& tmp = *get<I>(v_);
return addressof(tmp);
```

(5.3) — Otherwise, equivalent to: `return` ***proxy*`(*get<I>(v_));` where ***proxy*** is the exposition-only class:

```
class proxy {
  iter_value_t<I> keep_;
```

```
    constexpr proxy(iter_reference_t<I>&& x)
      : keep_(std::move(x)) {}
  public:
    constexpr const iter_value_t<I>* operator->() const noexcept {
      return addressof(keep_);
    }
  };
```

24.5.5.5 Navigation [common.iter.nav]

```
constexpr common_iterator& operator++();
```

1 *Hardened preconditions*: `holds_alternative<I>(v_)` is `true`.

2 *Effects*: Equivalent to `++get<I>(v_)`.

3 *Returns*: `*this`.

```
constexpr decltype(auto) operator++(int);
```

4 *Hardened preconditions*: `holds_alternative<I>(v_)` is `true`.

5 *Effects*: If `I` models `forward_iterator`, equivalent to:

```
common_iterator tmp = *this;
++*this;
return tmp;
```

Otherwise, if `requires(I& i) { { *i++ } -> can-reference; }` is `true` or

```
indirectly_readable<I> && constructible_from<iter_value_t<I>, iter_reference_t<I>> &&
move_constructible<iter_value_t<I>>
```

is `false`, equivalent to:

```
return get<I>(v_)++;
```

Otherwise, equivalent to:

```
postfix-proxy p(**this);
++*this;
return p;
```

where *postfix-proxy* is the exposition-only class:

```
class postfix-proxy {
  iter_value_t<I> keep_;
  constexpr postfix-proxy(iter_reference_t<I>&& x)
    : keep_(std::forward<iter_reference_t<I>>(x)) {}
public:
  constexpr const iter_value_t<I>& operator*() const noexcept {
    return keep_;
  }
};
```

24.5.5.6 Comparisons [common.iter.cmp]

```
template<class I2, sentinel_for<I> S2>
  requires sentinel_for<S, I2>
friend constexpr bool operator==(
  const common_iterator& x, const common_iterator<I2, S2>& y);
```

1 *Hardened preconditions*: `x.v_.valueless_by_exception()` and `y.v_.valueless_by_exception()` are each `false`.

2 *Returns*: `true` if i `==` j, and otherwise `get<`i`>(x.v_) == get<`j`>(y.v_)`, where i is `x.v_.index()` and j is `y.v_.index()`.

```
template<class I2, sentinel_for<I> S2>
  requires sentinel_for<S, I2> && equality_comparable_with<I, I2>
friend constexpr bool operator==(
  const common_iterator& x, const common_iterator<I2, S2>& y);
```

3 *Hardened preconditions*: `x.v_.valueless_by_exception()` and `y.v_.valueless_by_exception()` are each `false`.

4 *Returns*: `true` if i and j are each `1`, and otherwise `get<`i`>(x.v_) == get<`j`>(y.v_)`, where i is `x.v_.index()` and j is `y.v_.index()`.

```
template<sized_sentinel_for<I> I2, sized_sentinel_for<I> S2>
  requires sized_sentinel_for<S, I2>
friend constexpr iter_difference_t<I2> operator-(
  const common_iterator& x, const common_iterator<I2, S2>& y);
```

5 *Hardened preconditions*: `x.v_.valueless_by_exception()` and `y.v_.valueless_by_exception()` are each `false`.

6 *Returns*: `0` if i and j are each `1`, and otherwise `get<`i`>(x.v_) - get<`j`>(y.v_)`, where i is `x.v_.index()` and j is `y.v_.index()`.

24.5.5.7 Customizations [common.iter.cust]

```
friend constexpr decltype(auto) iter_move(const common_iterator& i)
  noexcept(noexcept(ranges::iter_move(declval<const I&>())))
    requires input_iterator<I>;
```

1 *Hardened preconditions*: `holds_alternative<I>(i.v_)` is `true`.

2 *Effects*: Equivalent to: `return ranges::iter_move(get<I>(i.v_));`

```
template<indirectly_swappable<I> I2, class S2>
  friend constexpr void iter_swap(const common_iterator& x, const common_iterator<I2, S2>& y)
    noexcept(noexcept(ranges::iter_swap(declval<const I&>(), declval<const I2&>())));
```

3 *Hardened preconditions*: `holds_alternative<I>(x.v_)` and `holds_alternative<I2>(y.v_)` are each `true`.

4 *Effects*: Equivalent to `ranges::iter_swap(get<I>(x.v_), get<I2>(y.v_))`.

24.5.6 Default sentinel [default.sentinel]

```
namespace std {
  struct default_sentinel_t { };
}
```

1 Class `default_sentinel_t` is an empty type used to denote the end of a range. It can be used together with iterator types that know the bound of their range (e.g., `counted_iterator` (24.5.7.1)).

24.5.7 Counted iterators [iterators.counted]

24.5.7.1 Class template `counted_iterator` [counted.iterator]

1 Class template `counted_iterator` is an iterator adaptor with the same behavior as the underlying iterator except that it keeps track of the distance to the end of its range. It can be used together with `default_sentinel` in calls to generic algorithms to operate on a range of N elements starting at a given position without needing to know the end position a priori.

2 [*Example 1*:

```
list<string> s;
// populate the list s with at least 10 strings
vector<string> v;
// copies 10 strings into v:
ranges::copy(counted_iterator(s.begin(), 10), default_sentinel, back_inserter(v));
```

— *end example*]

3 Two values `i1` and `i2` of types `counted_iterator<I1>` and `counted_iterator<I2>` refer to elements of the same sequence if and only if there exists some integer n such that `next(i1.base(), i1.count() +` n`)` and `next(i2.base(), i2.count() +` n`)` refer to the same (possibly past-the-end) element.

```
namespace std {
  template<input_or_output_iterator I>
  class counted_iterator {
  public:
    using iterator_type = I;
    using value_type = iter_value_t<I>;                          // present only
                         // if I models indirectly_readable
    using difference_type = iter_difference_t<I>;
    using iterator_concept = I::iterator_concept;                // present only
                         // if the qualified-id I::iterator_concept is valid and denotes a type
    using iterator_category = I::iterator_category;              // present only
                         // if the qualified-id I::iterator_category is valid and denotes a type
    constexpr counted_iterator() requires default_initializable<I> = default;
    constexpr counted_iterator(I x, iter_difference_t<I> n);
    template<class I2>
      requires convertible_to<const I2&, I>
        constexpr counted_iterator(const counted_iterator<I2>& x);

    template<class I2>
      requires assignable_from<I&, const I2&>
        constexpr counted_iterator& operator=(const counted_iterator<I2>& x);

    constexpr const I& base() const & noexcept;
    constexpr I base() &&;
    constexpr iter_difference_t<I> count() const noexcept;
    constexpr decltype(auto) operator*();
    constexpr decltype(auto) operator*() const
      requires dereferenceable<const I>;

    constexpr auto operator->() const noexcept
      requires contiguous_iterator<I>;

    constexpr counted_iterator& operator++();
    constexpr decltype(auto) operator++(int);
    constexpr counted_iterator operator++(int)
      requires forward_iterator<I>;
    constexpr counted_iterator& operator--()
      requires bidirectional_iterator<I>;
    constexpr counted_iterator operator--(int)
      requires bidirectional_iterator<I>;

    constexpr counted_iterator operator+(iter_difference_t<I> n) const
      requires random_access_iterator<I>;
    friend constexpr counted_iterator operator+(
      iter_difference_t<I> n, const counted_iterator& x)
        requires random_access_iterator<I>;
    constexpr counted_iterator& operator+=(iter_difference_t<I> n)
      requires random_access_iterator<I>;

    constexpr counted_iterator operator-(iter_difference_t<I> n) const
      requires random_access_iterator<I>;
    template<common_with<I> I2>
      friend constexpr iter_difference_t<I2> operator-(
        const counted_iterator& x, const counted_iterator<I2>& y);
    friend constexpr iter_difference_t<I> operator-(
      const counted_iterator& x, default_sentinel_t) noexcept;
    friend constexpr iter_difference_t<I> operator-(
      default_sentinel_t, const counted_iterator& y) noexcept;
    constexpr counted_iterator& operator-=(iter_difference_t<I> n)
      requires random_access_iterator<I>;

    constexpr decltype(auto) operator[](iter_difference_t<I> n) const
      requires random_access_iterator<I>;
```

```
    template<common_with<I> I2>
      friend constexpr bool operator==(
        const counted_iterator& x, const counted_iterator<I2>& y);
    friend constexpr bool operator==(
      const counted_iterator& x, default_sentinel_t) noexcept;

    template<common_with<I> I2>
      friend constexpr strong_ordering operator<=>(
        const counted_iterator& x, const counted_iterator<I2>& y);

    friend constexpr decltype(auto) iter_move(const counted_iterator& i)
      noexcept(noexcept(ranges::iter_move(i.current)))
        requires input_iterator<I>;
    template<indirectly_swappable<I> I2>
      friend constexpr void iter_swap(const counted_iterator& x, const counted_iterator<I2>& y)
        noexcept(noexcept(ranges::iter_swap(x.current, y.current)));

  private:
    I current = I();                    // exposition only
    iter_difference_t<I> length = 0;    // exposition only
  };

  template<input_iterator I>
    requires same_as<ITER_TRAITS(I), iterator_traits<I>>   // see 24.3.4.1
  struct iterator_traits<counted_iterator<I>> : iterator_traits<I> {
    using pointer = conditional_t<contiguous_iterator<I>,
                                  add_pointer_t<iter_reference_t<I>>, void>;
  };
}
```

24.5.7.2 Constructors and conversions [counted.iter.const]

```
constexpr counted_iterator(I i, iter_difference_t<I> n);
```

1 *Hardened preconditions*: `n >= 0` is `true`.

2 *Effects*: Initializes `current` with `std::move(i)` and `length` with `n`.

```
template<class I2>
  requires convertible_to<const I2&, I>
    constexpr counted_iterator(const counted_iterator<I2>& x);
```

3 *Effects*: Initializes `current` with `x.current` and `length` with `x.length`.

```
template<class I2>
  requires assignable_from<I&, const I2&>
    constexpr counted_iterator& operator=(const counted_iterator<I2>& x);
```

4 *Effects*: Assigns `x.current` to `current` and `x.length` to `length`.

5 *Returns*: `*this`.

24.5.7.3 Accessors [counted.iter.access]

```
constexpr const I& base() const & noexcept;
```

1 *Effects*: Equivalent to: `return current;`

```
constexpr I base() &&;
```

2 *Returns*: `std::move(current)`.

```
constexpr iter_difference_t<I> count() const noexcept;
```

3 *Effects*: Equivalent to: `return length;`

24.5.7.4 Element access [counted.iter.elem]

```
constexpr decltype(auto) operator*();
```

```
constexpr decltype(auto) operator*() const
  requires dereferenceable<const I>;
```

1 *Hardened preconditions*: `length > 0` is `true`.

2 *Effects*: Equivalent to: `return *current;`

```
constexpr auto operator->() const noexcept
  requires contiguous_iterator<I>;
```

3 *Effects*: Equivalent to: `return to_address(current);`

```
constexpr decltype(auto) operator[](iter_difference_t<I> n) const
  requires random_access_iterator<I>;
```

4 *Hardened preconditions*: `n < length` is `true`.

5 *Effects*: Equivalent to: `return current[n];`

24.5.7.5 Navigation [counted.iter.nav]

```
constexpr counted_iterator& operator++();
```

1 *Hardened preconditions*: `length > 0` is `true`.

2 *Effects*: Equivalent to:

```
++current;
--length;
return *this;
```

```
constexpr decltype(auto) operator++(int);
```

3 *Hardened preconditions*: `length > 0` is `true`.

4 *Effects*: Equivalent to:

```
--length;
try { return current++; }
catch(...) { ++length; throw; }
```

```
constexpr counted_iterator operator++(int)
  requires forward_iterator<I>;
```

5 *Effects*: Equivalent to:

```
counted_iterator tmp = *this;
++*this;
return tmp;
```

```
constexpr counted_iterator& operator--()
  requires bidirectional_iterator<I>;
```

6 *Effects*: Equivalent to:

```
--current;
++length;
return *this;
```

```
constexpr counted_iterator operator--(int)
  requires bidirectional_iterator<I>;
```

7 *Effects*: Equivalent to:

```
counted_iterator tmp = *this;
--*this;
return tmp;
```

```
constexpr counted_iterator operator+(iter_difference_t<I> n) const
  requires random_access_iterator<I>;
```

8 *Effects*: Equivalent to: `return counted_iterator(current + n, length - n);`

```
friend constexpr counted_iterator operator+(
  iter_difference_t<I> n, const counted_iterator& x)
    requires random_access_iterator<I>;
```

9 *Effects*: Equivalent to: `return x + n;`

```
constexpr counted_iterator& operator+=(iter_difference_t<I> n)
  requires random_access_iterator<I>;
```

10 *Hardened preconditions*: `n <= length` is `true`.

11 *Effects*: Equivalent to:

```
current += n;
length -= n;
return *this;
```

```
constexpr counted_iterator operator-(iter_difference_t<I> n) const
  requires random_access_iterator<I>;
```

12 *Effects*: Equivalent to: `return counted_iterator(current - n, length + n);`

```
template<common_with<I> I2>
  friend constexpr iter_difference_t<I2> operator-(
    const counted_iterator& x, const counted_iterator<I2>& y);
```

13 *Preconditions*: `x` and `y` refer to elements of the same sequence (24.5.7.1).

14 *Effects*: Equivalent to: `return y.length - x.length;`

```
friend constexpr iter_difference_t<I> operator-(
  const counted_iterator& x, default_sentinel_t) noexcept;
```

15 *Effects*: Equivalent to: `return -x.length;`

```
friend constexpr iter_difference_t<I> operator-(
  default_sentinel_t, const counted_iterator& y) noexcept;
```

16 *Effects*: Equivalent to: `return y.length;`

```
constexpr counted_iterator& operator-=(iter_difference_t<I> n)
  requires random_access_iterator<I>;
```

17 *Hardened preconditions*: `-n <= length` is `true`.

18 *Effects*: Equivalent to:

```
current -= n;
length += n;
return *this;
```

24.5.7.6 Comparisons [counted.iter.cmp]

```
template<common_with<I> I2>
  friend constexpr bool operator==(
    const counted_iterator& x, const counted_iterator<I2>& y);
```

1 *Preconditions*: `x` and `y` refer to elements of the same sequence (24.5.7.1).

2 *Effects*: Equivalent to: `return x.length == y.length;`

```
friend constexpr bool operator==(
  const counted_iterator& x, default_sentinel_t) noexcept;
```

3 *Effects*: Equivalent to: `return x.length == 0;`

```
template<common_with<I> I2>
  friend constexpr strong_ordering operator<=>(
    const counted_iterator& x, const counted_iterator<I2>& y);
```

4 *Preconditions*: `x` and `y` refer to elements of the same sequence (24.5.7.1).

5 *Effects*: Equivalent to: `return y.length <=> x.length;`

6 [*Note 1*: The argument order in the *Effects*: element is reversed because `length` counts down, not up. — *end note*]

24.5.7.7 Customizations [counted.iter.cust]

```
friend constexpr decltype(auto)
  iter_move(const counted_iterator& i)
    noexcept(noexcept(ranges::iter_move(i.current)))
    requires input_iterator<I>;
```

1 *Hardened preconditions*: `i.length > 0` is `true`.

2 *Effects*: Equivalent to: `return ranges::iter_move(i.current);`

```
template<indirectly_swappable<I> I2>
  friend constexpr void
    iter_swap(const counted_iterator& x, const counted_iterator<I2>& y)
      noexcept(noexcept(ranges::iter_swap(x.current, y.current)));
```

3 *Hardened preconditions*: Both `x.length > 0` and `y.length > 0` are `true`.

4 *Effects*: Equivalent to `ranges::iter_swap(x.current, y.current)`.

24.5.8 Unreachable sentinel [unreachable.sentinel]

1 Class `unreachable_sentinel_t` can be used with any `weakly_incrementable` type to denote the "upper bound" of an unbounded interval.

2 [*Example 1*:

```
char* p;
// set p to point to a character buffer containing newlines
char* nl = find(p, unreachable_sentinel, '\n');
```

Provided a newline character really exists in the buffer, the use of `unreachable_sentinel` above potentially makes the call to `find` more efficient since the loop test against the sentinel does not require a conditional branch. — *end example*]

```
namespace std {
  struct unreachable_sentinel_t {
    template<weakly_incrementable I>
      friend constexpr bool operator==(unreachable_sentinel_t, const I&) noexcept
      { return false; }
  };
}
```

24.6 Stream iterators [stream.iterators]

24.6.1 General [stream.iterators.general]

1 To make it possible for algorithmic templates to work directly with input/output streams, appropriate iterator-like class templates are provided.

[*Example 1*:

```
partial_sum(istream_iterator<double, char>(cin),
  istream_iterator<double, char>(),
  ostream_iterator<double, char>(cout, "\n"));
```

reads a file containing floating-point numbers from `cin`, and prints the partial sums onto `cout`. — *end example*]

24.6.2 Class template `istream_iterator` [istream.iterator]

24.6.2.1 General [istream.iterator.general]

1 The class template `istream_iterator` is an input iterator (24.3.5.3) that reads successive elements from the input stream for which it was constructed.

```
namespace std {
  template<class T, class charT = char, class traits = char_traits<charT>,
           class Distance = ptrdiff_t>
  class istream_iterator {
  public:
    using iterator_category = input_iterator_tag;
    using value_type        = T;
    using difference_type   = Distance;
    using pointer           = const T*;
```

```
    using reference         = const T&;
    using char_type         = charT;
    using traits_type       = traits;
    using istream_type      = basic_istream<charT,traits>;

    constexpr istream_iterator();
    constexpr istream_iterator(default_sentinel_t);
    istream_iterator(istream_type& s);
    constexpr istream_iterator(const istream_iterator& x) noexcept(see below);
    ~istream_iterator() = default;
    istream_iterator& operator=(const istream_iterator&) = default;

    const T& operator*() const;
    const T* operator->() const;
    istream_iterator& operator++();
    istream_iterator  operator++(int);

    friend bool operator==(const istream_iterator& i, default_sentinel_t);

  private:
    basic_istream<charT,traits>* in_stream; // exposition only
    T value;                                // exposition only
  };
}
```

2 The type `T` shall meet the *Cpp17DefaultConstructible*, *Cpp17CopyConstructible*, and *Cpp17CopyAssignable* requirements.

24.6.2.2 Constructors and destructor [istream.iterator.cons]

```
constexpr istream_iterator();
constexpr istream_iterator(default_sentinel_t);
```

1 *Effects*: Constructs the end-of-stream iterator, value-initializing `value`.

2 *Postconditions*: `in_stream == nullptr` is `true`.

3 *Remarks*: If the initializer `T()` in the declaration `auto x = T();` is a constant initializer (7.7.4), then these constructors are `constexpr` constructors.

```
istream_iterator(istream_type& s);
```

4 *Effects*: Initializes `in_stream` with `addressof(s)`, value-initializes `value`, and then calls `operator++()`.

```
constexpr istream_iterator(const istream_iterator& x) noexcept(see below);
```

5 *Effects*: Initializes `in_stream` with `x.in_stream` and initializes `value` with `x.value`.

6 *Remarks*: An invocation of this constructor may be used in a core constant expression if and only if the initialization of `value` from `x.value` is a constant subexpression (3.15). The exception specification is equivalent to `is_nothrow_copy_constructible_v<T>`.

```
~istream_iterator() = default;
```

7 *Remarks*: If `is_trivially_destructible_v<T>` is `true`, then this destructor is trivial.

24.6.2.3 Operations [istream.iterator.ops]

```
const T& operator*() const;
```

1 *Preconditions*: `in_stream != nullptr` is `true`.

2 *Returns*: `value`.

```
const T* operator->() const;
```

3 *Preconditions*: `in_stream != nullptr` is `true`.

4 *Returns*: `addressof(value)`.

```
istream_iterator& operator++();
```

5 *Preconditions*: `in_stream != nullptr` is `true`.

6 *Effects*: Equivalent to:

```
if (!(*in_stream >> value))
  in_stream = nullptr;
```

7 *Returns*: `*this`.

```
istream_iterator operator++(int);
```

8 *Preconditions*: `in_stream != nullptr` is `true`.

9 *Effects*: Equivalent to:

```
istream_iterator tmp = *this;
++*this;
return tmp;
```

```
template<class T, class charT, class traits, class Distance>
  bool operator==(const istream_iterator<T,charT,traits,Distance>& x,
                  const istream_iterator<T,charT,traits,Distance>& y);
```

10 *Returns*: `x.in_stream == y.in_stream`.

```
friend bool operator==(const istream_iterator& i, default_sentinel_t);
```

11 *Returns*: `!i.in_stream`.

24.6.3 Class template `ostream_iterator` [ostream.iterator]

24.6.3.1 General [ostream.iterator.general]

1 `ostream_iterator` writes (using `operator<<`) successive elements onto the output stream from which it was constructed. If it was constructed with `charT*` as a constructor argument, this string, called a *delimiter string*, is written to the stream after every `T` is written.

```
namespace std {
  template<class T, class charT = char, class traits = char_traits<charT>>
  class ostream_iterator {
  public:
    using iterator_category = output_iterator_tag;
    using value_type        = void;
    using difference_type   = ptrdiff_t;
    using pointer           = void;
    using reference         = void;
    using char_type         = charT;
    using traits_type       = traits;
    using ostream_type      = basic_ostream<charT,traits>;

    ostream_iterator(ostream_type& s);
    ostream_iterator(ostream_type& s, const charT* delimiter);
    ostream_iterator(const ostream_iterator& x);
    ~ostream_iterator();
    ostream_iterator& operator=(const ostream_iterator&) = default;
    ostream_iterator& operator=(const T& value);

    ostream_iterator& operator*();
    ostream_iterator& operator++();
    ostream_iterator& operator++(int);

  private:
    basic_ostream<charT,traits>* out_stream;          // exposition only
    const charT* delim;                               // exposition only
  };
}
```

24.6.3.2 Constructors and destructor [ostream.iterator.cons.des]

```
ostream_iterator(ostream_type& s);
```

1 *Effects*: Initializes `out_stream` with `addressof(s)` and `delim` with `nullptr`.

```
ostream_iterator(ostream_type& s, const charT* delimiter);
```

2 *Effects*: Initializes `out_stream` with `addressof(s)` and `delim` with `delimiter`.

24.6.3.3 Operations [ostream.iterator.ops]

```
ostream_iterator& operator=(const T& value);
```

1 *Effects*: As if by:

```
*out_stream << value;
if (delim)
  *out_stream << delim;
return *this;
```

```
ostream_iterator& operator*();
```

2 *Returns*: `*this`.

```
ostream_iterator& operator++();
ostream_iterator& operator++(int);
```

3 *Returns*: `*this`.

24.6.4 Class template `istreambuf_iterator` [istreambuf.iterator]

24.6.4.1 General [istreambuf.iterator.general]

1 The class template `istreambuf_iterator` defines an input iterator (24.3.5.3) that reads successive *characters* from the streambuf for which it was constructed. `operator*` provides access to the current input character, if any. Each time `operator++` is evaluated, the iterator advances to the next input character. If the end of stream is reached (`streambuf_type::sgetc()` returns `traits::eof()`), the iterator becomes equal to the *end-of-stream* iterator value. The default constructor `istreambuf_iterator()` and the constructor `istreambuf_iterator(nullptr)` both construct an end-of-stream iterator object suitable for use as an end-of-range. All specializations of `istreambuf_iterator` shall have a trivial copy constructor, a `constexpr` default constructor, and a trivial destructor.

2 The result of `operator*()` on an end-of-stream iterator is undefined. For any other iterator value a `char_type` value is returned. It is impossible to assign a character via an input iterator.

```
namespace std {
  template<class charT, class traits = char_traits<charT>>
  class istreambuf_iterator {
  public:
    using iterator_category = input_iterator_tag;
    using value_type        = charT;
    using difference_type   = traits::off_type;
    using pointer           = unspecified;
    using reference         = charT;
    using char_type         = charT;
    using traits_type       = traits;
    using int_type          = traits::int_type;
    using streambuf_type    = basic_streambuf<charT,traits>;
    using istream_type      = basic_istream<charT,traits>;

    // 24.6.4.2, class istreambuf_iterator::proxy
    class proxy;                          // exposition only

    constexpr istreambuf_iterator() noexcept;
    constexpr istreambuf_iterator(default_sentinel_t) noexcept;
    istreambuf_iterator(const istreambuf_iterator&) noexcept = default;
    ~istreambuf_iterator() = default;
    istreambuf_iterator(istream_type& s) noexcept;
    istreambuf_iterator(streambuf_type* s) noexcept;
```

©ISO/IEC

```
    istreambuf_iterator(const proxy& p) noexcept;
    istreambuf_iterator& operator=(const istreambuf_iterator&) noexcept = default;
    charT operator*() const;
    istreambuf_iterator& operator++();
    proxy operator++(int);
    bool equal(const istreambuf_iterator& b) const;

    friend bool operator==(const istreambuf_iterator& i, default_sentinel_t s);

  private:
    streambuf_type* sbuf_;              // exposition only
  };
}
```

24.6.4.2 Class `istreambuf_iterator::proxy` [istreambuf.iterator.proxy]

1 Class `istreambuf_iterator<charT,traits>::proxy` is for exposition only. An implementation is permitted to provide equivalent functionality without providing a class with this name. Class `istreambuf_iterator<charT, traits>::proxy` provides a temporary placeholder as the return value of the post-increment operator (`operator++`). It keeps the character pointed to by the previous value of the iterator for some possible future access to get the character.

```
namespace std {
  template<class charT, class traits>
  class istreambuf_iterator<charT, traits>::proxy { // exposition only
    charT keep_;
    basic_streambuf<charT,traits>* sbuf_;
    proxy(charT c, basic_streambuf<charT,traits>* sbuf)
      : keep_(c), sbuf_(sbuf) { }
  public:
    charT operator*() { return keep_; }
  };
}
```

24.6.4.3 Constructors [istreambuf.iterator.cons]

1 For each `istreambuf_iterator` constructor in this subclause, an end-of-stream iterator is constructed if and only if the exposition-only member `sbuf_` is initialized with a null pointer value.

```
constexpr istreambuf_iterator() noexcept;
constexpr istreambuf_iterator(default_sentinel_t) noexcept;
```

2 *Effects*: Initializes `sbuf_` with `nullptr`.

```
istreambuf_iterator(istream_type& s) noexcept;
```

3 *Effects*: Initializes `sbuf_` with `s.rdbuf()`.

```
istreambuf_iterator(streambuf_type* s) noexcept;
```

4 *Effects*: Initializes `sbuf_` with `s`.

```
istreambuf_iterator(const proxy& p) noexcept;
```

5 *Effects*: Initializes `sbuf_` with `p.sbuf_`.

24.6.4.4 Operations [istreambuf.iterator.ops]

```
charT operator*() const;
```

1 *Returns*: The character obtained via the `streambuf` member `sbuf_->sgetc()`.

```
istreambuf_iterator& operator++();
```

2 *Effects*: As if by `sbuf_->sbumpc()`.

3 *Returns*: `*this`.

```
proxy operator++(int);
```

4 *Returns*: `proxy(sbuf_->sbumpc(), sbuf_)`.

```
bool equal(const istreambuf_iterator& b) const;
```

5 *Returns*: `true` if and only if both iterators are at end-of-stream, or neither is at end-of-stream, regardless of what `streambuf` object they use.

```
template<class charT, class traits>
  bool operator==(const istreambuf_iterator<charT,traits>& a,
                  const istreambuf_iterator<charT,traits>& b);
```

6 *Returns*: `a.equal(b)`.

```
friend bool operator==(const istreambuf_iterator& i, default_sentinel_t s);
```

7 *Returns*: `i.equal(s)`.

24.6.5 Class template `ostreambuf_iterator` [ostreambuf.iterator]

24.6.5.1 General [ostreambuf.iterator.general]

1 The class template `ostreambuf_iterator` writes successive *characters* onto the output stream from which it was constructed.

```
namespace std {
  template<class charT, class traits = char_traits<charT>>
  class ostreambuf_iterator {
  public:
    using iterator_category = output_iterator_tag;
    using value_type        = void;
    using difference_type   = ptrdiff_t;
    using pointer           = void;
    using reference         = void;
    using char_type         = charT;
    using traits_type       = traits;
    using streambuf_type    = basic_streambuf<charT,traits>;
    using ostream_type      = basic_ostream<charT,traits>;

    ostreambuf_iterator(ostream_type& s) noexcept;
    ostreambuf_iterator(streambuf_type* s) noexcept;
    ostreambuf_iterator& operator=(charT c);

    ostreambuf_iterator& operator*();
    ostreambuf_iterator& operator++();
    ostreambuf_iterator& operator++(int);
    bool failed() const noexcept;

  private:
    streambuf_type* sbuf_;              // exposition only
  };
}
```

24.6.5.2 Constructors [ostreambuf.iter.cons]

```
ostreambuf_iterator(ostream_type& s) noexcept;
```

1 *Preconditions*: `s.rdbuf()` is not a null pointer.

2 *Effects*: Initializes `sbuf_` with `s.rdbuf()`.

```
ostreambuf_iterator(streambuf_type* s) noexcept;
```

3 *Preconditions*: `s` is not a null pointer.

4 *Effects*: Initializes `sbuf_` with `s`.

24.6.5.3 Operations [ostreambuf.iter.ops]

```
ostreambuf_iterator& operator=(charT c);
```

1 *Effects*: If `failed()` yields `false`, calls `sbuf_->sputc(c)`; otherwise has no effect.

2 *Returns*: `*this`.

```
ostreambuf_iterator& operator*();
```

3 *Returns*: `*this`.

```
ostreambuf_iterator& operator++();
ostreambuf_iterator& operator++(int);
```

4 *Returns*: `*this`.

```
bool failed() const noexcept;
```

5 *Returns*: `true` if in any prior use of member `operator=`, the call to `sbuf_->sputc()` returned `traits::eof()`; or `false` otherwise.

24.7 Range access [iterator.range]

1 In addition to being available via inclusion of the `<iterator>` header, the function templates in 24.7 are available when any of the following headers are included:

(1.1) — `<array>` (23.3.2)

(1.2) — `<deque>` (23.3.4)

(1.3) — `<flat_map>` (23.6.7)

(1.4) — `<flat_set>` (23.6.10)

(1.5) — `<forward_list>` (23.3.6)

(1.6) — `<hive>` (23.3.8)

(1.7) — `<inplace_vector>` (23.3.15)

(1.8) — `<list>` (23.3.10)

(1.9) — `<map>` (23.4.2)

(1.10) — `<optional>` (22.5.2)

(1.11) — `<regex>` (28.6.3)

(1.12) — `<set>` (23.4.5)

(1.13) — `<span>` (23.7.2.1)

(1.14) — `<stacktrace>` (19.6.2)

(1.15) — `<string>` (27.4.2)

(1.16) — `<string_view>` (27.3.2)

(1.17) — `<unordered_map>` (23.5.2)

(1.18) — `<unordered_set>` (23.5.5)

(1.19) — `<valarray>` (29.6.1)

(1.20) — `<vector>` (23.3.12)

```
template<class C> constexpr auto begin(C& c) noexcept(noexcept(c.begin()))
  -> decltype(c.begin());
template<class C> constexpr auto begin(const C& c) noexcept(noexcept(c.begin()))
  -> decltype(c.begin());
```

2 *Returns*: `c.begin()`.

```
template<class C> constexpr auto end(C& c) noexcept(noexcept(c.end())) -> decltype(c.end());
template<class C> constexpr auto end(const C& c) noexcept(noexcept(c.end())) -> decltype(c.end());
```

3 *Returns*: `c.end()`.

```
template<class T, size_t N> constexpr T* begin(T (&array)[N]) noexcept;
```

4 *Returns*: `array`.

```
template<class T, size_t N> constexpr T* end(T (&array)[N]) noexcept;
```

5 *Returns*: `array + N`.

```
template<class C> constexpr auto cbegin(const C& c) noexcept(noexcept(std::begin(c)))
  -> decltype(std::begin(c));
```

6 *Returns*: `std::begin(c)`.

```
template<class C> constexpr auto cend(const C& c) noexcept(noexcept(std::end(c)))
  -> decltype(std::end(c));
```

7 *Returns*: `std::end(c)`.

```
template<class C> constexpr auto rbegin(C& c) noexcept(noexcept(c.rbegin()))
  -> decltype(c.rbegin());
template<class C> constexpr auto rbegin(const C& c) noexcept(noexcept(c.rbegin()))
  -> decltype(c.rbegin());
```

8 *Returns*: `c.rbegin()`.

```
template<class C> constexpr auto rend(C& c) noexcept(noexcept(c.rend())) -> decltype(c.rend());
template<class C> constexpr auto rend(const C& c) noexcept(noexcept(c.rend()))
  -> decltype(c.rend());
```

9 *Returns*: `c.rend()`.

```
template<class T, size_t N> constexpr reverse_iterator<T*> rbegin(T (&array)[N]) noexcept;
```

10 *Returns*: `reverse_iterator<T*>(array + N)`.

```
template<class T, size_t N> constexpr reverse_iterator<T*> rend(T (&array)[N]) noexcept;
```

11 *Returns*: `reverse_iterator<T*>(array)`.

```
template<class E> constexpr reverse_iterator<const E*> rbegin(initializer_list<E> il) noexcept;
```

12 *Returns*: `reverse_iterator<const E*>(il.end())`.

```
template<class E> constexpr reverse_iterator<const E*> rend(initializer_list<E> il) noexcept;
```

13 *Returns*: `reverse_iterator<const E*>(il.begin())`.

```
template<class C> constexpr auto crbegin(const C& c) noexcept(noexcept(std::rbegin(c)))
  -> decltype(std::rbegin(c));
```

14 *Returns*: `std::rbegin(c)`.

```
template<class C> constexpr auto crend(const C& c) noexcept(noexcept(c.crend()))
  -> decltype(std::rend(c));
```

15 *Returns*: `std::rend(c)`.

```
template<class C> constexpr auto size(const C& c) noexcept(noexcept(c.size()))
  -> decltype(c.size());
```

16 *Returns*: `c.size()`.

```
template<class T, size_t N> constexpr size_t size(const T (&array)[N]) noexcept;
```

17 *Returns*: `N`.

```
template<class C> constexpr auto ssize(const C& c) noexcept(noexcept(c.size()))
  -> common_type_t<ptrdiff_t, make_signed_t<decltype(c.size())>>;
```

18 *Effects*: Equivalent to:

```
  return static_cast<common_type_t<ptrdiff_t, make_signed_t<decltype(c.size())>>>(c.size());
```

```
template<class T, ptrdiff_t N> constexpr ptrdiff_t ssize(const T (&array)[N]) noexcept;
```

19 *Returns*: `N`.

```
template<class C> constexpr auto empty(const C& c) noexcept(noexcept(c.empty()))
  -> decltype(c.empty());
```

20 *Returns*: `c.empty()`.

```
template<class T, size_t N> constexpr bool empty(const T (&array)[N]) noexcept;
```

21 *Returns*: `false`.

```
template<class C> constexpr auto data(C& c) noexcept(noexcept(c.data())) -> decltype(c.data());
template<class C> constexpr auto data(const C& c) noexcept(noexcept(c.data()))
  -> decltype(c.data());
```

22 *Returns*: `c.data()`.

```
template<class T, size_t N> constexpr T* data(T (&array)[N]) noexcept;
```

23 *Returns*: `array`.

©ISO/IEC

25 Ranges library [ranges]

25.1 General [ranges.general]

1 This Clause describes components for dealing with ranges of elements.

2 The following subclauses describe range and view requirements, and components for range primitives and range generators as summarized in Table 84.

Table 84 — Ranges library summary [tab:range.summary]

	Subclause	Header
25.3	Range access	`<ranges>`
25.4	Requirements	
25.5	Range utilities	
25.6	Range factories	
25.7	Range adaptors	
25.8	Range generators	`<generator>`

25.2 Header `<ranges>` synopsis [ranges.syn]

```
// mostly freestanding
#include <compare>              // see 17.12.1
#include <initializer_list>     // see 17.11.2
#include <iterator>             // see 24.2

namespace std::ranges {
  inline namespace unspecified {
    // 25.3, range access
    inline constexpr unspecified begin = unspecified;
    inline constexpr unspecified end = unspecified;
    inline constexpr unspecified cbegin = unspecified;
    inline constexpr unspecified cend = unspecified;

  inline constexpr from_range_t from_range{};
}
```

1 Within this Clause, for an integer-like type `X` (24.3.4.4), *`make-unsigned-like-t`*`<X>` denotes `make_unsigned_t<X>` if `X` is an integer type; otherwise, it denotes a corresponding unspecified unsigned-integer-like type of the same width as `X`. For an expression `x` of type `X`, *`to-unsigned-like`*`(x)` is `x` explicitly converted to *`make-unsigned-like-t`*`<X>`.

2 Also within this Clause, *`make-signed-like-t`*`<X>` for an integer-like type `X` denotes `make_signed_t<X>` if `X` is an integer type; otherwise, it denotes a corresponding unspecified signed-integer-like type of the same width as `X`.

25.3 Range access [range.access]

25.3.1 General [range.access.general]

1 In addition to being available via inclusion of the `<ranges>` header, the customization point objects in 25.3 are available when the header `<iterator>` (24.2) is included.

2 Within 25.3, the *reified object* of a subexpression `E` denotes

(2.1) — the same object as `E` if `E` is a glvalue, or

(2.2) — the result of applying the temporary materialization conversion (7.3.5) to `E` otherwise.

25.3.2 `ranges::begin` [range.access.begin]

1 The name `ranges::begin` denotes a customization point object (16.3.3.3.5).

2 Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

(2.1) — If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is `false`, `ranges::begin(E)` is ill-formed.

(2.2) — Otherwise, if `T` is an array type (9.3.4.5) and `remove_all_extents_t<T>` is an incomplete type, `ranges::begin(E)` is ill-formed with no diagnostic required.

(2.3) — Otherwise, if `T` is an array type, `ranges::begin(E)` is expression-equivalent to `t + 0`.

(2.4) — Otherwise, if `auto(t.begin())` is a valid expression whose type models `input_or_output_iterator`, `ranges::begin(E)` is expression-equivalent to `auto(t.begin())`.

(2.5) — Otherwise, if `T` is a class or enumeration type and `auto(begin(t))` is a valid expression whose type models `input_or_output_iterator` where the meaning of `begin` is established as-if by performing argument-dependent lookup only (6.5.4), then `ranges::begin(E)` is expression-equivalent to that expression.

(2.6) — Otherwise, `ranges::begin(E)` is ill-formed.

3 [*Note 1*: Diagnosable ill-formed cases above result in substitution failure when `ranges::begin(E)` appears in the immediate context of a template instantiation. — *end note*]

4 [*Note 2*: Whenever `ranges::begin(E)` is a valid expression, its type models `input_or_output_iterator`. — *end note*]

25.3.3 `ranges::end` [range.access.end]

1 The name `ranges::end` denotes a customization point object (16.3.3.3.5).

2 Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

(2.1) — If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is `false`, `ranges::end(E)` is ill-formed.

(2.2) — Otherwise, if `T` is an array type (9.3.4.5) and `remove_all_extents_t<T>` is an incomplete type, `ranges::end(E)` is ill-formed with no diagnostic required.

(2.3) — Otherwise, if `T` is an array of unknown bound, `ranges::end(E)` is ill-formed.

(2.4) — Otherwise, if `T` is an array, `ranges::end(E)` is expression-equivalent to `t + extent_v<T>`.

(2.5) — Otherwise, if `auto(t.end())` is a valid expression whose type models `sentinel_for<iterator_t<T>>` then `ranges::end(E)` is expression-equivalent to `auto(t.end())`.

(2.6) — Otherwise, if `T` is a class or enumeration type and `auto(end(t))` is a valid expression whose type models `sentinel_for<iterator_t<T>>` where the meaning of `end` is established as-if by performing argument-dependent lookup only (6.5.4), then `ranges::end(E)` is expression-equivalent to that expression.

(2.7) — Otherwise, `ranges::end(E)` is ill-formed.

3 [*Note 1*: Diagnosable ill-formed cases above result in substitution failure when `ranges::end(E)` appears in the immediate context of a template instantiation. — *end note*]

4 [*Note 2*: Whenever `ranges::end(E)` is a valid expression, the types `S` and `I` of `ranges::end(E)` and `ranges::begin(E)` model `sentinel_for<S, I>`. — *end note*]

25.3.4 `ranges::cbegin` [range.access.cbegin]

1 The name `ranges::cbegin` denotes a customization point object (16.3.3.3.5). Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

(1.1) — If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is `false`, `ranges::cbegin(E)` is ill-formed.

(1.2) — Otherwise, let `U` be `ranges::begin(`*`possibly-const-range`*`(t))`. `ranges::cbegin(E)` is expression-equivalent to `const_iterator<decltype(U)>(U)`.

2 [*Note 1*: Whenever `ranges::cbegin(E)` is a valid expression, its type models `input_or_output_iterator` and *`constant-iterator`*. — *end note*]

25.3.5 `ranges::cend` [range.access.cend]

1 The name `ranges::cend` denotes a customization point object (16.3.3.3.5). Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

(1.1) — If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is `false`, `ranges::cend(E)` is ill-formed.

(1.2) — Otherwise, let `U` be `ranges::end(`*`possibly-const-range`*`(t))`. `ranges::cend(E)` is expression-equivalent to `const_sentinel<decltype(U)>(U)`.

2 [*Note 1*: Whenever `ranges::cend(E)` is a valid expression, the types `S` and `I` of the expressions `ranges::cend(E)` and `ranges::cbegin(E)` model `sentinel_for<S, I>`. If `S` models `input_iterator`, then `S` also models *`constant-iterator`*. — *end note*]

25.3.6 `ranges::rbegin` [range.access.rbegin]

1 The name `ranges::rbegin` denotes a customization point object (16.3.3.3.5).

2 Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

(2.1) — If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is `false`, `ranges::rbegin(E)` is ill-formed.

(2.2) — Otherwise, if `T` is an array type (9.3.4.5) and `remove_all_extents_t<T>` is an incomplete type, `ranges::rbegin(E)` is ill-formed with no diagnostic required.

(2.3) — Otherwise, if `auto(t.rbegin())` is a valid expression whose type models `input_or_output_iterator`, `ranges::rbegin(E)` is expression-equivalent to `auto(t.rbegin())`.

(2.4) — Otherwise, if `T` is a class or enumeration type and `auto(rbegin(t))` is a valid expression whose type models `input_or_output_iterator` where the meaning of `rbegin` is established as-if by performing argument-dependent lookup only (6.5.4), then `ranges::rbegin(E)` is expression-equivalent to that expression.

(2.5) — Otherwise, if both `ranges::begin(t)` and `ranges::end(t)` are valid expressions of the same type which models `bidirectional_iterator` (24.3.4.12), `ranges::rbegin(E)` is expression-equivalent to `make_reverse_iterator(ranges::end(t))`.

(2.6) — Otherwise, `ranges::rbegin(E)` is ill-formed.

3 [*Note 1*: Diagnosable ill-formed cases above result in substitution failure when `ranges::rbegin(E)` appears in the immediate context of a template instantiation. — *end note*]

4 [*Note 2*: Whenever `ranges::rbegin(E)` is a valid expression, its type models `input_or_output_iterator`. — *end note*]

25.3.7 `ranges::rend` [range.access.rend]

1 The name `ranges::rend` denotes a customization point object (16.3.3.3.5).

2 Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

(2.1) — If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is `false`, `ranges::rend(E)` is ill-formed.

(2.2) — Otherwise, if `T` is an array type (9.3.4.5) and `remove_all_extents_t<T>` is an incomplete type, `ranges::rend(E)` is ill-formed with no diagnostic required.

(2.3) — Otherwise, if `auto(t.rend())` is a valid expression whose type models `sentinel_for<decltype(ranges::rbegin(E))>` then `ranges::rend(E)` is expression-equivalent to `auto(t.rend())`.

(2.4) — Otherwise, if `T` is a class or enumeration type and `auto(rend(t))` is a valid expression whose type models `sentinel_for<decltype(ranges::rbegin(E))>` where the meaning of `rend` is established as-if by performing argument-dependent lookup only (6.5.4), then `ranges::rend(E)` is expression-equivalent to that expression.

(2.5) — Otherwise, if both `ranges::begin(t)` and `ranges::end(t)` are valid expressions of the same type which models `bidirectional_iterator` (24.3.4.12), then `ranges::rend(E)` is expression-equivalent to `make_reverse_iterator(ranges::begin(t))`.

(2.6) — Otherwise, `ranges::rend(E)` is ill-formed.

3 [*Note 1*: Diagnosable ill-formed cases above result in substitution failure when `ranges::rend(E)` appears in the immediate context of a template instantiation. — *end note*]

4 [*Note 2*: Whenever `ranges::rend(E)` is a valid expression, the types `S` and `I` of the expressions `ranges::rend(E)` and `ranges::rbegin(E)` model `sentinel_for<S, I>`. — *end note*]

25.3.8 `ranges::crbegin` [range.access.crbegin]

1 The name `ranges::crbegin` denotes a customization point object (16.3.3.3.5). Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

(1.1) — If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is `false`, `ranges::crbegin(E)` is ill-formed.

(1.2) — Otherwise, let `U` be `ranges::rbegin(`*`possibly-const-range`*`(t))`. `ranges::crbegin(E)` is expression-equivalent to `const_iterator<decltype(U)>(U)`.

2 [*Note 1*: Whenever `ranges::crbegin(E)` is a valid expression, its type models `input_or_output_iterator` and *`constant-iterator`*. — *end note*]

25.3.9 `ranges::crend` [range.access.crend]

1 The name `ranges::crend` denotes a customization point object (16.3.3.3.5). Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

(1.1) — If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is `false`, `ranges::crend(E)` is ill-formed.

(1.2) — Otherwise, let `U` be `ranges::rend(`*`possibly-const-range`*`(t))`. `ranges::crend(E)` is expression-equivalent to `const_sentinel<decltype(U)>(U)`.

2 [*Note 1*: Whenever `ranges::crend(E)` is a valid expression, the types `S` and `I` of the expressions `ranges::crend(E)` and `ranges::crbegin(E)` model `sentinel_for<S, I>`. If `S` models `input_iterator`, then `S` also models *`constant-iterator`*. — *end note*]

25.3.10 `ranges::size` [range.prim.size]

1 The name `ranges::size` denotes a customization point object (16.3.3.3.5).

2 Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

(2.1) — If `T` is an array of unknown bound (9.3.4.5), `ranges::size(E)` is ill-formed.

(2.2) — Otherwise, if `T` is an array type, `ranges::size(E)` is expression-equivalent to `auto(extent_v<T>)`.

(2.3) — Otherwise, if `disable_sized_range<remove_cv_t<T>>` (25.4.4) is `false` and `auto(t.size())` is a valid expression of integer-like type (24.3.4.4), `ranges::size(E)` is expression-equivalent to `auto(t.size())`.

(2.4) — Otherwise, if `T` is a class or enumeration type, `disable_sized_range<remove_cv_t<T>>` is `false` and `auto(size(t))` is a valid expression of integer-like type where the meaning of `size` is established as-if by performing argument-dependent lookup only (6.5.4), then `ranges::size(E)` is expression-equivalent to that expression.

(2.5) — Otherwise, if *`to-unsigned-like`*`(ranges::end(t) - ranges::begin(t))` (25.2) is a valid expression and the types `I` and `S` of `ranges::begin(t)` and `ranges::end(t)` (respectively) model both `sized_sentinel_for<S, I>` (24.3.4.8) and `forward_iterator<I>`, then `ranges::size(E)` is expression-equivalent to *`to-unsigned-like`*`(ranges::end(t) - ranges::begin(t))`.

(2.6) — Otherwise, `ranges::size(E)` is ill-formed.

3 [*Note 1*: Diagnosable ill-formed cases above result in substitution failure when `ranges::size(E)` appears in the immediate context of a template instantiation. — *end note*]

4 [*Note 2*: Whenever `ranges::size(E)` is a valid expression, its type is integer-like. — *end note*]

25.3.11 `ranges::ssize` [range.prim.ssize]

1 The name `ranges::ssize` denotes a customization point object (16.3.3.3.5).

2 Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. If `ranges::size(t)` is ill-formed, `ranges::ssize(E)` is ill-formed. Otherwise let `D` be *`make-signed-like-t`*`<decltype(ranges::size(t))>`, or `ptrdiff_t` if it is wider than that type; `ranges::ssize(E)` is expression-equivalent to `static_cast<D>(ranges::size(t))`.

25.3.12 `ranges::reserve_hint` [range.prim.size.hint]

1 The name `ranges::reserve_hint` denotes a customization point object (16.3.3.3.5).

2 Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

(2.1) — If `ranges::size(E)` is a valid expression, `ranges::reserve_hint(E)` is expression-equivalent to `ranges::size(E)`.

(2.2) — Otherwise, if `auto(t.reserve_hint())` is a valid expression of integer-like type (24.3.4.4), `ranges::reserve_hint(E)` is expression-equivalent to `auto(t.reserve_hint())`.

(2.3) — Otherwise, if `T` is a class or enumeration type and `auto(reserve_hint(t))` is a valid expression of integer-like type where the meaning of `reserve_hint` is established as-if by performing argument-dependent lookup only (6.5.4), then `ranges::reserve_hint(E)` is expression-equivalent to that expression.

©ISO/IEC

(2.4) — Otherwise, `ranges::reserve_hint(E)` is ill-formed.

[*Note 1*: Diagnosable ill-formed cases above result in substitution failure when `ranges::reserve_hint(E)` appears in the immediate context of a template instantiation. — *end note*]

[*Note 2*: Whenever `ranges::reserve_hint(E)` is a valid expression, its type is integer-like. — *end note*]

25.3.13 `ranges::empty` [range.prim.empty]

1 The name `ranges::empty` denotes a customization point object (16.3.3.3.5).

2 Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

(2.1) — If `T` is an array of unknown bound (9.3.4.5), `ranges::empty(E)` is ill-formed.

(2.2) — Otherwise, if `bool(t.empty())` is a valid expression, `ranges::empty(E)` is expression-equivalent to `bool(t.empty())`.

(2.3) — Otherwise, if `(ranges::size(t) == 0)` is a valid expression, `ranges::empty(E)` is expression-equivalent to `(ranges::size(t) == 0)`.

(2.4) — Otherwise, if `bool(ranges::begin(t) == ranges::end(t))` is a valid expression and the type of `ranges::begin(t)` models `forward_iterator`, `ranges::empty(E)` is expression-equivalent to `bool(ranges::begin(t) == ranges::end(t))`.

(2.5) — Otherwise, `ranges::empty(E)` is ill-formed.

3 [*Note 1*: Diagnosable ill-formed cases above result in substitution failure when `ranges::empty(E)` appears in the immediate context of a template instantiation. — *end note*]

4 [*Note 2*: Whenever `ranges::empty(E)` is a valid expression, it has type `bool`. — *end note*]

25.3.14 `ranges::data` [range.prim.data]

1 The name `ranges::data` denotes a customization point object (16.3.3.3.5).

2 Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

(2.1) — If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is `false`, `ranges::data(E)` is ill-formed.

(2.2) — Otherwise, if `T` is an array type (9.3.4.5) and `remove_all_extents_t<T>` is an incomplete type, `ranges::data(E)` is ill-formed with no diagnostic required.

(2.3) — Otherwise, if `auto(t.data())` is a valid expression of pointer to object type, `ranges::data(E)` is expression-equivalent to `auto(t.data())`.

(2.4) — Otherwise, if `ranges::begin(t)` is a valid expression whose type models `contiguous_iterator`, `ranges::data(E)` is expression-equivalent to `to_address(ranges::begin(t))`.

(2.5) — Otherwise, `ranges::data(E)` is ill-formed.

3 [*Note 1*: Diagnosable ill-formed cases above result in substitution failure when `ranges::data(E)` appears in the immediate context of a template instantiation. — *end note*]

4 [*Note 2*: Whenever `ranges::data(E)` is a valid expression, it has pointer to object type. — *end note*]

25.3.15 `ranges::cdata` [range.prim.cdata]

```
template<class T>
constexpr auto as-const-pointer(const T* p) noexcept { return p; }  // exposition only
```

1 The name `ranges::cdata` denotes a customization point object (16.3.3.3.5). Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

(1.1) — If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is `false`, `ranges::cdata(E)` is ill-formed.

(1.2) — Otherwise, `ranges::cdata(E)` is expression-equivalent to *`as-const-pointer`*`(ranges::data(`*`possibly-const-range`*`(t)))`.

2 [*Note 1*: Whenever `ranges::cdata(E)` is a valid expression, it has pointer to constant object type. — *end note*]

©ISO/IEC

25.4 Range requirements [range.req]

25.4.1 General [range.req.general]

1 Ranges are an abstraction that allows a C++ program to operate on elements of data structures uniformly. Calling `ranges::begin` on a range returns an object whose type models `input_or_output_iterator` (24.3.4.6). Calling `ranges::end` on a range returns an object whose type `S`, together with the type `I` of the object returned by `ranges::begin`, models `sentinel_for<S, I>`. The library formalizes the interfaces, semantics, and complexity of ranges to enable algorithms and range adaptors that work efficiently on different types of sequences.

2 The `range` concept requires that `ranges::begin` and `ranges::end` return an iterator and a sentinel, respectively. The `sized_range` concept refines `range` with the requirement that `ranges::size` be amortized $\mathcal{O}(1)$. The `view` concept specifies requirements on a `range` type to provide operations with predictable complexity.

3 Several refinements of `range` group requirements that arise frequently in concepts and algorithms. Common ranges are ranges for which `ranges::begin` and `ranges::end` return objects of the same type. Random access ranges are ranges for which `ranges::begin` returns a type that models `random_access_iterator` (24.3.4.13). (Contiguous, bidirectional, forward, input, and output ranges are defined similarly.) Viewable ranges can be converted to views.

25.4.2 Ranges [range.range]

1 The `range` concept defines the requirements of a type that allows iteration over its elements by providing an iterator and sentinel that denote the elements of the range.

```
template<class T>
  concept range =
    requires(T& t) {
      ranges::begin(t);          // sometimes equality-preserving (see below)
      ranges::end(t);
    };
```

2 Given an expression `t` such that `decltype((t))` is `T&`, `T` models `range` only if

(2.1) — [`ranges::begin(t)`, `ranges::end(t)`) denotes a range (24.3.1),

(2.2) — both `ranges::begin(t)` and `ranges::end(t)` are amortized constant time and non-modifying, and

(2.3) — if the type of `ranges::begin(t)` models `forward_iterator`, `ranges::begin(t)` is equality-preserving.

3 [*Note 1*: Equality preservation of both `ranges::begin` and `ranges::end` enables passing a range whose iterator type models `forward_iterator` to multiple algorithms and making multiple passes over the range by repeated calls to `ranges::begin` and `ranges::end`. Since `ranges::begin` is not required to be equality-preserving when the return type does not model `forward_iterator`, it is possible for repeated calls to not return equal values or to not be well-defined. — *end note*]

```
template<class T>
  concept borrowed_range =
    range<T> && (is_lvalue_reference_v<T> || enable_borrowed_range<remove_cvref_t<T>>);
```

4 Let `U` be `remove_reference_t<T>` if `T` is an rvalue reference type, and `T` otherwise. Given a variable `u` of type `U`, `T` models `borrowed_range` only if the validity of iterators obtained from `u` is not tied to the lifetime of that variable.

5 [*Note 2*: Since the validity of iterators is not tied to the lifetime of a variable whose type models `borrowed_range`, a function with a parameter of such a type can return iterators obtained from it without danger of dangling. — *end note*]

```
template<class>
  constexpr bool enable_borrowed_range = false;
```

6 *Remarks*: Pursuant to 16.4.5.2.1, users may specialize `enable_borrowed_range` for cv-unqualified program-defined types. Such specializations shall be usable in constant expressions (7.7.4) and have type `const bool`.

7 [*Example 1*: Each specialization `S` of class template `subrange` (25.5.4) models `borrowed_range` because

(7.1) — `enable_borrowed_range<S>` is specialized to have the value `true`, and

(7.2) — `S`'s iterators do not have validity tied to the lifetime of an `S` object because they are "borrowed" from some other range.

— *end example*]

25.4.3 Approximately sized ranges [range.approximately.sized]

1 The `approximately_sized_range` concept refines `range` with the requirement that an approximation of the number of elements in the range can be determined in amortized constant time using `ranges::reserve_hint`.

```
template<class T>
  concept approximately_sized_range =
    range<T> && requires(T& t) { ranges::reserve_hint(t); };
```

2 Given an lvalue `t` of type `remove_reference_t<T>`, `T` models `approximately_sized_range` only if

(2.1) — `ranges::reserve_hint(t)` is amortized $\mathcal{O}(1)$, does not modify `t`, and has a value that is not negative and is representable in `range_difference_t<T>`, and

(2.2) — if `iterator_t<T>` models `forward_iterator`, `ranges::reserve_hint(t)` is well-defined regardless of the evaluation of `ranges::begin(t)`.

[*Note 1*: `ranges::reserve_hint(t)` is otherwise not required to be well-defined after evaluating `ranges::begin(t)`. For example, it is possible for `ranges::reserve_hint(t)` to be well-defined for an `approximately_sized_range` whose iterator type does not model `forward_iterator` only if evaluated before the first call to `ranges::begin(t)`. — *end note*]

25.4.4 Sized ranges [range.sized]

1 The `sized_range` concept refines `approximately_sized_range` with the requirement that the number of elements in the range can be determined in amortized constant time using `ranges::size`.

```
template<class T>
  concept sized_range =
    approximately_sized_range<T> && requires(T& t) { ranges::size(t); };
```

2 Given an lvalue `t` of type `remove_reference_t<T>`, `T` models `sized_range` only if

(2.1) — `ranges::size(t)` is amortized $\mathcal{O}(1)$, does not modify `t`, and is equal to `ranges::distance(ranges::begin(t), ranges::end(t))`, and

(2.2) — if `iterator_t<T>` models `forward_iterator`, `ranges::size(t)` is well-defined regardless of the evaluation of `ranges::begin(t)`.

[*Note 1*: `ranges::size(t)` is otherwise not required to be well-defined after evaluating `ranges::begin(t)`. For example, it is possible for `ranges::size(t)` to be well-defined for a `sized_range` whose iterator type does not model `forward_iterator` only if evaluated before the first call to `ranges::begin(t)`. — *end note*]

```
template<class>
  constexpr bool disable_sized_range = false;
```

3 *Remarks*: Pursuant to 16.4.5.2.1, users may specialize `disable_sized_range` for cv-unqualified program-defined types. Such specializations shall be usable in constant expressions (7.7.4) and have type `const bool`.

4 [*Note 2*: `disable_sized_range` allows use of `range` types with the library that satisfy but do not in fact model `sized_range`. — *end note*]

25.4.5 Views [range.view]

1 The `view` concept specifies the requirements of a `range` type that has the semantic properties below, which make it suitable for use in constructing range adaptor pipelines (25.7).

```
template<class T>
  concept view =
    range<T> && movable<T> && enable_view<T>;
```

2 `T` models `view` only if

(2.1) — `T` has $\mathcal{O}(1)$ move construction; and

(2.2) — move assignment of an object of type `T` is no more complex than destruction followed by move construction; and

(2.3) — if N copies and/or moves are made from an object of type `T` that contained M elements, then those N objects have $\mathcal{O}(N + M)$ destruction; and

(2.4) — `copy_constructible<T>` is `false`, or `T` has $\mathcal{O}(1)$ copy construction; and

(2.5) — `copyable<T>` is `false`, or copy assignment of an object of type `T` is no more complex than destruction followed by copy construction.

3 [*Note 1*: The constraints on copying and moving imply that a moved-from object of type `T` has $\mathcal{O}(1)$ destruction. — *end note*]

4 [*Example 1*: Examples of views are:

(4.1) — A `range` type that wraps a pair of iterators.

(4.2) — A `range` type that holds its elements by `shared_ptr` and shares ownership with all its copies.

(4.3) — A `range` type that generates its elements on demand.

A container such as `vector<string>` does not meet the semantic requirements of `view` since copying the container copies all of the elements, which cannot be done in constant time. — *end example*]

5 Since the difference between `range` and `view` is largely semantic, the two are differentiated with the help of `enable_view`.

```
template<class T>
  constexpr bool is-derived-from-view-interface = see below;          // exposition only
template<class T>
  constexpr bool enable_view =
    derived_from<T, view_base> || is-derived-from-view-interface<T>;
```

6 For a type `T`, *`is-derived-from-view-interface`*`<T>` is `true` if and only if `T` has exactly one public base class `view_interface<U>` for some type `U` and `T` has no base classes of type `view_interface<V>` for any other type `V`.

7 *Remarks*: Pursuant to 16.4.5.2.1, users may specialize `enable_view` to `true` for cv-unqualified program-defined types that model `view`, and `false` for types that do not. Such specializations shall be usable in constant expressions (7.7.4) and have type `const bool`.

25.4.6 Other range refinements [range.refinements]

1 The `output_range` concept specifies requirements of a `range` type for which `ranges::begin` returns a model of `output_iterator` (24.3.4.10). `input_range`, `forward_range`, `bidirectional_range`, and `random_access_range` are defined similarly.

```
template<class R, class T>
  concept output_range =
    range<R> && output_iterator<iterator_t<R>, T>;

template<class T>
  concept input_range =
    range<T> && input_iterator<iterator_t<T>>;

template<class T>
  concept forward_range =
    input_range<T> && forward_iterator<iterator_t<T>>;

template<class T>
  concept bidirectional_range =
    forward_range<T> && bidirectional_iterator<iterator_t<T>>;

template<class T>
  concept random_access_range =
    bidirectional_range<T> && random_access_iterator<iterator_t<T>>;
```

2 `contiguous_range` additionally requires that the `ranges::data` customization point object (25.3.14) is usable with the range.

```
template<class T>
  concept contiguous_range =
    random_access_range<T> && contiguous_iterator<iterator_t<T>> &&
    requires(T& t) {
      { ranges::data(t) } -> same_as<add_pointer_t<range_reference_t<T>>>;
    };
```

3 Given an expression `t` such that `decltype((t))` is `T&`, `T` models `contiguous_range` only if `to_address(ranges::begin(t)) == ranges::data(t)` is `true`.

4 The `common_range` concept specifies requirements of a `range` type for which `ranges::begin` and `ranges::end` return objects of the same type.

[*Example 1*: The standard containers (Clause 23) model `common_range`. — *end example*]

```
template<class T>
  concept common_range =
    range<T> && same_as<iterator_t<T>, sentinel_t<T>>;

template<class R>
  constexpr bool is-initializer-list = see below;                    // exposition only
```

5 For a type `R`, *`is-initializer-list`*`<R>` is `true` if and only if `remove_cvref_t<R>` is a specialization of `initializer_list`.

6 The `viewable_range` concept specifies the requirements of a `range` type that can be converted to a view safely.

```
template<class T>
  concept viewable_range =
    range<T> &&
    ((view<remove_cvref_t<T>> && constructible_from<remove_cvref_t<T>, T>) ||
     (!view<remove_cvref_t<T>> &&
      (is_lvalue_reference_v<T> || (movable<remove_reference_t<T>> && !is-initializer-list<T>))));
```

7 The `constant_range` concept specifies the requirements of a `range` type whose elements are not modifiable.

```
template<class T>
  concept constant_range =
    input_range<T> && constant-iterator<iterator_t<T>>;
```

8 The exposition-only concept *`sized-random-access-range`* specifies the requirements of a `range` type that is sized and allows random access to its elements.

```
template<class T>
  concept sized-random-access-range =            // exposition only
    random_access_range<T> && sized_range<T>;
```

[*Note 1*: This concept constrains some parallel algorithm overloads; see Clause 26. — *end note*]

25.5 Range utilities [range.utility]

25.5.1 General [range.utility.general]

1 The components in 25.5 are general utilities for representing and manipulating ranges.

25.5.2 Helper concepts [range.utility.helpers]

1 Many of the types in 25.5 are specified in terms of the following exposition-only concepts:

```
template<class R>
  concept simple-view =                                          // exposition only
    view<R> && range<const R> &&
    same_as<iterator_t<R>, iterator_t<const R>> &&
    same_as<sentinel_t<R>, sentinel_t<const R>>;

template<class I>
  concept has-arrow =                                            // exposition only
    input_iterator<I> && (is_pointer_v<I> || requires(const I i) { i.operator->(); });
```

```
template<class T, class U>
  concept different-from =                                    // exposition only
    !same_as<remove_cvref_t<T>, remove_cvref_t<U>>;

template<class R>
  concept range-with-movable-references =                     // exposition only
    input_range<R> && move_constructible<range_reference_t<R>> &&
    move_constructible<range_rvalue_reference_t<R>>;
```

25.5.3 View interface [view.interface]

25.5.3.1 General [view.interface.general]

1 The class template `view_interface` is a helper for defining view-like types that offer a container-like interface. It is parameterized with the type that is derived from it.

```
namespace std::ranges {
  template<class D>
    requires is_class_v<D> && same_as<D, remove_cv_t<D>>
  class view_interface {
  private:
    constexpr D& derived() noexcept {                // exposition only
      return static_cast<D&>(*this);
    }
    constexpr const D& derived() const noexcept {    // exposition only
      return static_cast<const D&>(*this);
    }

  public:
    constexpr bool empty() requires sized_range<D> || forward_range<D> {
      if constexpr (sized_range<D>)
        return ranges::size(derived()) == 0;
      else
        return ranges::begin(derived()) == ranges::end(derived());
    }
    constexpr bool empty() const requires sized_range<const D> || forward_range<const D> {
      if constexpr (sized_range<const D>)
        return ranges::size(derived()) == 0;
      else
        return ranges::begin(derived()) == ranges::end(derived());
    }

    constexpr auto cbegin() requires input_range<D> {
      return ranges::cbegin(derived());
    }
    constexpr auto cbegin() const requires input_range<const D> {
      return ranges::cbegin(derived());
    }
    constexpr auto cend() requires input_range<D> {
      return ranges::cend(derived());
    }
    constexpr auto cend() const requires input_range<const D> {
      return ranges::cend(derived());
    }

    constexpr explicit operator bool()
      requires requires { ranges::empty(derived()); } {
        return !ranges::empty(derived());
      }
    constexpr explicit operator bool() const
      requires requires { ranges::empty(derived()); } {
        return !ranges::empty(derived());
      }
```

```
    constexpr auto data() requires contiguous_iterator<iterator_t<D>> {
      return to_address(ranges::begin(derived()));
    }
    constexpr auto data() const
      requires range<const D> && contiguous_iterator<iterator_t<const D>> {
        return to_address(ranges::begin(derived()));
      }

    constexpr auto size() requires forward_range<D> &&
      sized_sentinel_for<sentinel_t<D>, iterator_t<D>> {
        return to-unsigned-like(ranges::end(derived()) - ranges::begin(derived()));
      }
    constexpr auto size() const requires forward_range<const D> &&
      sized_sentinel_for<sentinel_t<const D>, iterator_t<const D>> {
        return to-unsigned-like(ranges::end(derived()) - ranges::begin(derived()));
      }

    constexpr decltype(auto) front() requires forward_range<D>;
    constexpr decltype(auto) front() const requires forward_range<const D>;

    constexpr decltype(auto) back() requires bidirectional_range<D> && common_range<D>;
    constexpr decltype(auto) back() const
      requires bidirectional_range<const D> && common_range<const D>;

    template<random_access_range R = D>
      constexpr decltype(auto) operator[](range_difference_t<R> n) {
        return ranges::begin(derived())[n];
      }
    template<random_access_range R = const D>
      constexpr decltype(auto) operator[](range_difference_t<R> n) const {
        return ranges::begin(derived())[n];
      }
  };
}
```

[2] The template parameter `D` for `view_interface` may be an incomplete type. Before any member of the resulting specialization of `view_interface` other than special member functions is referenced, `D` shall be complete, and model both `derived_from<view_interface<D>>` and `view`.

25.5.3.2 Members [view.interface.members]

```
constexpr decltype(auto) front() requires forward_range<D>;
constexpr decltype(auto) front() const requires forward_range<const D>;
```

[1] *Hardened preconditions*: `!empty()` is `true`.

[2] *Effects*: Equivalent to: `return *ranges::begin(derived());`

```
constexpr decltype(auto) back() requires bidirectional_range<D> && common_range<D>;
constexpr decltype(auto) back() const
  requires bidirectional_range<const D> && common_range<const D>;
```

[3] *Hardened preconditions*: `!empty()` is `true`.

[4] *Effects*: Equivalent to: `return *ranges::prev(ranges::end(derived()));`

25.5.4 Sub-ranges [range.subrange]

25.5.4.1 General [range.subrange.general]

[1] The `subrange` class template combines together an iterator and a sentinel into a single object that models the `view` concept. Additionally, it models the `sized_range` concept when the final template parameter is `subrange_kind::sized`.

```
namespace std::ranges {
  template<class From, class To>
    concept uses-nonqualification-pointer-conversion =       // exposition only
      is_pointer_v<From> && is_pointer_v<To> &&
      !convertible_to<remove_pointer_t<From>(*)[], remove_pointer_t<To>(*)[]>;
```

```
template<class From, class To>
  concept convertible-to-non-slicing =                    // exposition only
    convertible_to<From, To> &&
    !uses-nonqualification-pointer-conversion<decay_t<From>, decay_t<To>>;

template<class T, class U, class V>
  concept pair-like-convertible-from =                    // exposition only
    !range<T> && !is_reference_v<T> && pair-like<T> &&
    constructible_from<T, U, V> &&
    convertible-to-non-slicing<U, tuple_element_t<0, T>> &&
    convertible_to<V, tuple_element_t<1, T>>;

template<input_or_output_iterator I, sentinel_for<I> S = I, subrange_kind K =
    sized_sentinel_for<S, I> ? subrange_kind::sized : subrange_kind::unsized>
  requires (K == subrange_kind::sized || !sized_sentinel_for<S, I>)
class subrange : public view_interface<subrange<I, S, K>> {
private:
  static constexpr bool StoreSize =                       // exposition only
    K == subrange_kind::sized && !sized_sentinel_for<S, I>;
  I begin_ = I();                                         // exposition only
  S end_ = S();                                           // exposition only
  make-unsigned-like-t<iter_difference_t<I>> size_ = 0;   // exposition only; present only
                                                          // if StoreSize is true
public:
  subrange() requires default_initializable<I> = default;

  constexpr subrange(convertible-to-non-slicing<I> auto i, S s) requires (!StoreSize);

  constexpr subrange(convertible-to-non-slicing<I> auto i, S s,
                     make-unsigned-like-t<iter_difference_t<I>> n)
    requires (K == subrange_kind::sized);

  template<different-from<subrange> R>
    requires borrowed_range<R> &&
             convertible-to-non-slicing<iterator_t<R>, I> &&
             convertible_to<sentinel_t<R>, S>
  constexpr subrange(R&& r) requires (!StoreSize || sized_range<R>);

  template<borrowed_range R>
    requires convertible-to-non-slicing<iterator_t<R>, I> &&
             convertible_to<sentinel_t<R>, S>
  constexpr subrange(R&& r, make-unsigned-like-t<iter_difference_t<I>> n)
    requires (K == subrange_kind::sized)
      : subrange{ranges::begin(r), ranges::end(r), n} {}

  template<different-from<subrange> PairLike>
    requires pair-like-convertible-from<PairLike, const I&, const S&>
  constexpr operator PairLike() const;

  constexpr I begin() const requires copyable<I>;
  constexpr I begin() requires (!copyable<I>);
  constexpr S end() const;

  constexpr bool empty() const;
  constexpr make-unsigned-like-t<iter_difference_t<I>> size() const
    requires (K == subrange_kind::sized);

  constexpr subrange next(iter_difference_t<I> n = 1) const &
    requires forward_iterator<I>;
  constexpr subrange next(iter_difference_t<I> n = 1) &&;
  constexpr subrange prev(iter_difference_t<I> n = 1) const
    requires bidirectional_iterator<I>;
  constexpr subrange& advance(iter_difference_t<I> n);
};
```

©ISO/IEC

```
  template<input_or_output_iterator I, sentinel_for<I> S>
    subrange(I, S) -> subrange<I, S>;

  template<input_or_output_iterator I, sentinel_for<I> S>
    subrange(I, S, make-unsigned-like-t<iter_difference_t<I>>) ->
      subrange<I, S, subrange_kind::sized>;

  template<borrowed_range R>
    subrange(R&&) ->
      subrange<iterator_t<R>, sentinel_t<R>,
               (sized_range<R> || sized_sentinel_for<sentinel_t<R>, iterator_t<R>>)
                 ? subrange_kind::sized : subrange_kind::unsized>;

  template<borrowed_range R>
    subrange(R&&, make-unsigned-like-t<range_difference_t<R>>) ->
      subrange<iterator_t<R>, sentinel_t<R>, subrange_kind::sized>;
}
```

25.5.4.2 Constructors and conversions [range.subrange.ctor]

```
constexpr subrange(convertible-to-non-slicing<I> auto i, S s) requires (!StoreSize);
```

1 *Preconditions*: $[\texttt{i}, \texttt{s})$ is a valid range.

2 *Effects*: Initializes *begin_* with `std::move(i)` and *end_* with `s`.

```
constexpr subrange(convertible-to-non-slicing<I> auto i, S s,
                   make-unsigned-like-t<iter_difference_t<I>> n)
  requires (K == subrange_kind::sized);
```

3 *Preconditions*: $[\texttt{i}, \texttt{s})$ is a valid range, and `n ==` *to-unsigned-like*`(ranges::distance(i, s))` is `true`.

4 *Effects*: Initializes *begin_* with `std::move(i)` and *end_* with `s`. If *StoreSize* is `true`, initializes *size_* with `n`.

5 [*Note 1*: Accepting the length of the range and storing it to later return from `size()` enables `subrange` to model `sized_range` even when it stores an iterator and sentinel that do not model `sized_sentinel_for`. — *end note*]

```
template<different-from<subrange> R>
  requires borrowed_range<R> &&
           convertible-to-non-slicing<iterator_t<R>, I> &&
           convertible_to<sentinel_t<R>, S>
constexpr subrange(R&& r) requires (!StoreSize || sized_range<R>);
```

6 *Effects*: Equivalent to:

(6.1) — If *StoreSize* is `true`, `subrange(r, static_cast<decltype(size_)>(ranges::size(r)))`.

(6.2) — Otherwise, `subrange(ranges::begin(r), ranges::end(r))`.

```
template<different-from<subrange> PairLike>
  requires pair-like-convertible-from<PairLike, const I&, const S&>
constexpr operator PairLike() const;
```

7 *Effects*: Equivalent to: `return PairLike(begin_, end_);`

25.5.4.3 Accessors [range.subrange.access]

```
constexpr I begin() const requires copyable<I>;
```

1 *Effects*: Equivalent to: `return begin_;`

```
constexpr I begin() requires (!copyable<I>);
```

2 *Effects*: Equivalent to: `return std::move(begin_);`

```
constexpr S end() const;
```

3 *Effects*: Equivalent to: `return end_;`

```
constexpr bool empty() const;
```

4 *Effects*: Equivalent to: `return begin_ == end_;`

```
constexpr make-unsigned-like-t<iter_difference_t<I>> size() const
  requires (K == subrange_kind::sized);
```

5 *Effects*:

(5.1) — If *StoreSize* is `true`, equivalent to: `return size_;`

(5.2) — Otherwise, equivalent to: `return to-unsigned-like(end_ - begin_);`

```
constexpr subrange next(iter_difference_t<I> n = 1) const &
  requires forward_iterator<I>;
```

6 *Effects*: Equivalent to:

```
auto tmp = *this;
tmp.advance(n);
return tmp;
```

```
constexpr subrange next(iter_difference_t<I> n = 1) &&;
```

7 *Effects*: Equivalent to:

```
advance(n);
return std::move(*this);
```

```
constexpr subrange prev(iter_difference_t<I> n = 1) const
  requires bidirectional_iterator<I>;
```

8 *Effects*: Equivalent to:

```
auto tmp = *this;
tmp.advance(-n);
return tmp;
```

```
constexpr subrange& advance(iter_difference_t<I> n);
```

9 *Effects*: Equivalent to:

```
if constexpr (bidirectional_iterator<I>) {
  if (n < 0) {
    ranges::advance(begin_, n);
    if constexpr (StoreSize)
      size_ += to-unsigned-like(-n);
    return *this;
  }
}

auto d = n - ranges::advance(begin_, n, end_);
if constexpr (StoreSize)
  size_ -= to-unsigned-like(d);
return *this;
```

```
template<size_t N, class I, class S, subrange_kind K>
  requires ((N == 0 && copyable<I>) || N == 1)
  constexpr auto get(const subrange<I, S, K>& r);
template<size_t N, class I, class S, subrange_kind K>
  requires (N < 2)
  constexpr auto get(subrange<I, S, K>&& r);
```

10 *Effects*: Equivalent to:

```
if constexpr (N == 0)
  return r.begin();
else
  return r.end();
```

25.5.5 Dangling iterator handling [range.dangling]

1 The type `dangling` is used together with the template aliases `borrowed_iterator_t` and `borrowed_subrange_t`. When an algorithm that typically returns an iterator into, or a subrange of, a range argument is called with an rvalue range argument that does not model `borrowed_range` (25.4.2), the return value possibly refers to a range whose lifetime has ended. In such cases, the type `dangling` is returned instead of an iterator or subrange.

```
namespace std::ranges {
  struct dangling {
    constexpr dangling() noexcept = default;
    constexpr dangling(auto&&...) noexcept {}
  };
}
```

2 [*Example 1*:

```
vector<int> f();
auto result1 = ranges::find(f(), 42);                                   // #1
static_assert(same_as<decltype(result1), ranges::dangling>);
auto vec = f();
auto result2 = ranges::find(vec, 42);                                   // #2
static_assert(same_as<decltype(result2), vector<int>::iterator>);
auto result3 = ranges::find(ranges::subrange{vec}, 42);                 // #3
static_assert(same_as<decltype(result3), vector<int>::iterator>);
```

The call to `ranges::find` at #1 returns `ranges::dangling` since `f()` is an rvalue `vector`; it is possible for the `vector` to be destroyed before a returned iterator is dereferenced. However, the calls at #2 and #3 both return iterators since the lvalue `vec` and specializations of `subrange` model `borrowed_range`. — *end example*]

3 For a type `R` that models `range`:

(3.1) — if `R` models `borrowed_range`, then `borrowed_iterator_t<R>` denotes `iterator_t<R>`, and `borrowed_subrange_t<R>` denotes `subrange<iterator_t<R>>`;

(3.2) — otherwise, both `borrowed_iterator_t<R>` and `borrowed_subrange_t<R>` denote `dangling`.

25.5.6 Class template `elements_of` [range.elementsof]

Specializations of `elements_of` encapsulate a range and act as a tag in overload sets to disambiguate when a range should be treated as a sequence rather than a single value.

[*Example 1*:

```
template<bool YieldElements>
generator<any> f(ranges::input_range auto&& r) {
  if constexpr (YieldElements)
    co_yield ranges::elements_of(r);        // yield each element of r
  else
    co_yield r;                             // yield r as a single value
}
```

— *end example*]

```
namespace std::ranges {
  template<range R, class Allocator = allocator<byte>>
  struct elements_of {
    [[no_unique_address]] R range;
    [[no_unique_address]] Allocator allocator = Allocator();
  };

  template<class R, class Allocator = allocator<byte>>
    elements_of(R&&, Allocator = Allocator()) -> elements_of<R&&, Allocator>;
}
```

25.5.7 Range conversions [range.utility.conv]

25.5.7.1 General [range.utility.conv.general]

1 The range conversion functions construct an object (usually a container) from a range, by using a constructor taking a range, a `from_range_t` tagged constructor, or a constructor taking a pair of iterators, or by inserting each element of the range into the default-constructed object.

2 `ranges::to` is applied recursively, allowing the conversion of a range of ranges.

[*Example 1*:

```
string_view str = "the quick brown fox";
auto words = views::split(str, ' ') | to<vector<string>>();
// words is vector<string>{"the", "quick", "brown", "fox"}
```

— *end example*]

3 Let *reservable-container* be defined as follows:

```
template<class Container>
constexpr bool reservable-container =          // exposition only
  sized_range<Container> &&
  requires(Container& c, range_size_t<Container> n) {
    c.reserve(n);
    { c.capacity() } -> same_as<decltype(n)>;
    { c.max_size() } -> same_as<decltype(n)>;
  };
```

4 Let *container-appendable* be defined as follows:

```
template<class Container, class Ref>
constexpr bool container-appendable =          // exposition only
  requires(Container& c, Ref&& ref) {
    requires (requires { c.emplace_back(std::forward<Ref>(ref)); } ||
              requires { c.push_back(std::forward<Ref>(ref)); } ||
              requires { c.emplace(c.end(), std::forward<Ref>(ref)); } ||
              requires { c.insert(c.end(), std::forward<Ref>(ref)); });
  };
```

5 Let *container-append* be defined as follows:

```
template<class Container>
constexpr auto container-append(Container& c) {                    // exposition only
  return [&c]<class Ref>(Ref&& ref) {
    if constexpr (requires { c.emplace_back(declval<Ref>()); })
      c.emplace_back(std::forward<Ref>(ref));
    else if constexpr (requires { c.push_back(declval<Ref>()); })
      c.push_back(std::forward<Ref>(ref));
    else if constexpr (requires { c.emplace(c.end(), declval<Ref>()); })
      c.emplace(c.end(), std::forward<Ref>(ref));
    else
      c.insert(c.end(), std::forward<Ref>(ref));
  };
}
```

25.5.7.2 `ranges::to` [range.utility.conv.to]

```
template<class C, input_range R, class... Args> requires (!view<C>)
  constexpr C to(R&& r, Args&&... args);
```

1 *Mandates*: `C` is a cv-unqualified class type.

2 *Returns*: An object of type `C` constructed from the elements of `r` in the following manner:

(2.1) — If `C` does not satisfy `input_range` or `convertible_to<range_reference_t<R>, range_value_t<C>>` is `true`:

(2.1.1) — If `constructible_from<C, R, Args...>` is `true`:

```
C(std::forward<R>(r), std::forward<Args>(args)...)
```

(2.1.2) — Otherwise, if `constructible_from<C, from_range_t, R, Args...>` is `true`:

```
C(from_range, std::forward<R>(r), std::forward<Args>(args)...)
```

(2.1.3) — Otherwise, if

(2.1.3.1) — `common_range<R>` is `true`,

(2.1.3.2) — the *qualified-id* `iterator_traits<iterator_t<R>>::iterator_category` is valid and denotes a type that models `derived_from<input_iterator_tag>`, and

(2.1.3.3) — `constructible_from<C, iterator_t<R>, sentinel_t<R>, Args...>` is `true`:

```
C(ranges::begin(r), ranges::end(r), std::forward<Args>(args)...)
```

(2.1.4) — Otherwise, if

(2.1.4.1) — `constructible_from<C, Args...>` is `true`, and

(2.1.4.2) — *`container-appendable`*`<C, range_reference_t<R>>` is `true`:

```
C c(std::forward<Args>(args)...);
if constexpr (approximately_sized_range<R> && reservable-container<C>)
  c.reserve(static_cast<range_size_t<C>>(ranges::reserve_hint(r)));
ranges::for_each(r, container-append(c));
```

(2.1.5) — Otherwise, the program is ill-formed.

(2.2) — Otherwise, if `input_range<range_reference_t<R>>` is `true`:

```
to<C>(ref_view(r) | views::transform([](auto&& elem) {
  return to<range_value_t<C>>(std::forward<decltype(elem)>(elem));
}), std::forward<Args>(args)...);
```

(2.3) — Otherwise, the program is ill-formed.

```
template<template<class...> class C, input_range R, class... Args>
  constexpr auto to(R&& r, Args&&... args);
```

3 Let *`input-iterator`* be an exposition-only type:

```
struct input-iterator {                          // exposition only
  using iterator_category = input_iterator_tag;
  using value_type = range_value_t<R>;
  using difference_type = ptrdiff_t;
  using pointer = add_pointer_t<range_reference_t<R>>;
  using reference = range_reference_t<R>;
  reference operator*() const;
  pointer operator->() const;
  input-iterator& operator++();
  input-iterator operator++(int);
  bool operator==(const input-iterator&) const;
};
```

[*Note 1*: *`input-iterator`* meets the syntactic requirements of *Cpp17InputIterator*. — *end note*]

4 Let *`DEDUCE_EXPR`* be defined as follows:

(4.1) — `C(declval<R>(), declval<Args>()...)` if that is a valid expression,

(4.2) — otherwise, `C(from_range, declval<R>(), declval<Args>()...)` if that is a valid expression,

(4.3) — otherwise,

```
C(declval<input-iterator>(), declval<input-iterator>(), declval<Args>()...)
```

if that is a valid expression,

(4.4) — otherwise, the program is ill-formed.

5 *Returns*: `to<decltype(`*`DEDUCE_EXPR`*`)>(std::forward<R>(r), std::forward<Args>(args)...)`.

25.5.7.3 `ranges::to` adaptors [range.utility.conv.adaptors]

```
template<class C, class... Args> requires (!view<C>)
  constexpr auto to(Args&&... args);
template<template<class...> class C, class... Args>
  constexpr auto to(Args&&... args);
```

1 *Mandates*: For the first overload, `C` is a cv-unqualified class type.

2 *Returns*: A range adaptor closure object (25.7.2) `f` that is a perfect forwarding call wrapper (22.10.4) with the following properties:

(2.1) — It has no target object.

(2.2) — Its bound argument entities `bound_args` consist of objects of types `decay_t<Args>...` direct-non-list-initialized with `std::forward<Args>(args)...`, respectively.

(2.3) — Its call pattern is `to<C>(r, bound_args...)`, where `r` is the argument used in a function call expression of `f`.

25.6 Range factories [range.factories]

25.6.1 General [range.factories.general]

1 Subclause 25.6 defines *range factories*, which are utilities to create a view.

2 Range factories are declared in namespace `std::ranges::views`.

25.6.2 Empty view [range.empty]

25.6.2.1 Overview [range.empty.overview]

1 `empty_view` produces a view of no elements of a particular type.

2 [*Example 1*:

```
auto e = views::empty<int>;
static_assert(ranges::empty(e));
static_assert(0 == e.size());
```

— *end example*]

25.6.2.2 Class template `empty_view` [range.empty.view]

```
namespace std::ranges {
  template<class T>
    requires is_object_v<T>
  class empty_view : public view_interface<empty_view<T>> {
  public:
    static constexpr T* begin() noexcept { return nullptr; }
    static constexpr T* end() noexcept { return nullptr; }
    static constexpr T* data() noexcept { return nullptr; }
    static constexpr size_t size() noexcept { return 0; }
    static constexpr bool empty() noexcept { return true; }
  };
}
```

25.6.3 Single view [range.single]

25.6.3.1 Overview [range.single.overview]

1 `single_view` produces a view that contains exactly one element of a specified value.

2 The name `views::single` denotes a customization point object (16.3.3.3.5). Given a subexpression `E`, the expression `views::single(E)` is expression-equivalent to `single_view<decay_t<decltype((E))>>(E)`.

3 [*Example 1*:

```
for (int i : views::single(4))
  cout << i;        // prints 4
```

— *end example*]

25.6.3.2 Class template `single_view` [range.single.view]

```
namespace std::ranges {
  template<move_constructible T>
    requires is_object_v<T>
  class single_view : public view_interface<single_view<T>> {
  private:
    movable-box<T> value_;              // exposition only (see 25.7.3)

  public:
    single_view() requires default_initializable<T> = default;
    constexpr explicit single_view(const T& t) requires copy_constructible<T>;
    constexpr explicit single_view(T&& t);
    template<class... Args>
      requires constructible_from<T, Args...>
    constexpr explicit single_view(in_place_t, Args&&... args);
```

```
    constexpr T* begin() noexcept;
    constexpr const T* begin() const noexcept;
    constexpr T* end() noexcept;
    constexpr const T* end() const noexcept;
    static constexpr bool empty() noexcept;
    static constexpr size_t size() noexcept;
    constexpr T* data() noexcept;
    constexpr const T* data() const noexcept;
  };

  template<class T>
    single_view(T) -> single_view<T>;
}
```

```
constexpr explicit single_view(const T& t) requires copy_constructible<T>;
```

1 *Effects*: Initializes *value_* with `t`.

```
constexpr explicit single_view(T&& t);
```

2 *Effects*: Initializes *value_* with `std::move(t)`.

```
template<class... Args>
  requires constructible_from<T, Args...>
constexpr explicit single_view(in_place_t, Args&&... args);
```

3 *Effects*: Initializes *value_* as if by *value_*`{in_place, std::forward<Args>(args)...}`.

```
constexpr T* begin() noexcept;
constexpr const T* begin() const noexcept;
```

4 *Effects*: Equivalent to: `return data();`

```
constexpr T* end() noexcept;
constexpr const T* end() const noexcept;
```

5 *Effects*: Equivalent to: `return data() + 1;`

```
static constexpr bool empty() noexcept;
```

6 *Effects*: Equivalent to: `return false;`

```
static constexpr size_t size() noexcept;
```

7 *Effects*: Equivalent to: `return 1;`

```
constexpr T* data() noexcept;
constexpr const T* data() const noexcept;
```

8 *Effects*: Equivalent to: `return` *value_*`.operator->();`

25.6.4 Iota view [range.iota]

25.6.4.1 Overview [range.iota.overview]

1 `iota_view` generates a sequence of elements by repeatedly incrementing an initial value.

2 The name `views::iota` denotes a customization point object (16.3.3.3.5). Given subexpressions `E` and `F`, the expressions `views::iota(E)` and `views::iota(E, F)` are expression-equivalent to `iota_view<decay_t<decltype((E))>>(E)` and `iota_view(E, F)`, respectively.

3 [*Example 1*:

```
for (int i : views::iota(1, 10))
  cout << i << ' '; // prints 1 2 3 4 5 6 7 8 9
```

— *end example*]

4 The name `views::indices` denotes a customization point object (16.3.3.3.5). Given subexpression `E`, let `T` be `remove_cvref_t<decltype((E))>`. `views::indices(E)` is expression-equivalent to `views::iota(T(0), E)` if *is-integer-like*`<T>` is `true`, and ill-formed otherwise.

25.6.4.2 Class template `iota_view` [range.iota.view]

```
namespace std::ranges {
  template<class I>
    concept decrementable = see below;  // exposition only

  template<class I>
    concept advanceable = see below;    // exposition only

  template<weakly_incrementable W, semiregular Bound = unreachable_sentinel_t>
    requires weakly-equality-comparable-with<W, Bound> && copyable<W>
  class iota_view : public view_interface<iota_view<W, Bound>> {
  private:
    // 25.6.4.3, class iota_view::iterator
    struct iterator;                    // exposition only

    // 25.6.4.4, class iota_view::sentinel
    struct sentinel;                    // exposition only

    W value_ = W();                     // exposition only
    Bound bound_ = Bound();             // exposition only

  public:
    iota_view() requires default_initializable<W> = default;
    constexpr explicit iota_view(W value);
    constexpr explicit iota_view(type_identity_t<W> value, type_identity_t<Bound> bound);
    constexpr explicit iota_view(iterator first, see below last);

    constexpr iterator begin() const;
    constexpr auto end() const;
    constexpr iterator end() const requires same_as<W, Bound>;

    constexpr bool empty() const;
    constexpr auto size() const requires see below;
  };

  template<class W, class Bound>
    requires (!is-integer-like<W> || !is-integer-like<Bound> ||
              (is-signed-integer-like<W> == is-signed-integer-like<Bound>))
    iota_view(W, Bound) -> iota_view<W, Bound>;
}
```

1 Let *IOTA-DIFF-T*(`W`) be defined as follows:

(1.1) — If `W` is not an integral type, or if it is an integral type and `sizeof(iter_difference_t<W>)` is greater than `sizeof(W)`, then *IOTA-DIFF-T*(`W`) denotes `iter_difference_t<W>`.

(1.2) — Otherwise, *IOTA-DIFF-T*(`W`) is a signed integer type of width greater than the width of `W` if such a type exists.

(1.3) — Otherwise, *IOTA-DIFF-T*(`W`) is an unspecified signed-integer-like type (24.3.4.4) of width not less than the width of `W`.

[*Note 1*: It is unspecified whether this type satisfies `weakly_incrementable`. — *end note*]

2 The exposition-only *decrementable* concept is equivalent to:

```
template<class I>
  concept decrementable =                // exposition only
    incrementable<I> && requires(I i) {
      { --i } -> same_as<I&>;
      { i-- } -> same_as<I>;
    };
```

3 When an object is in the domain of both pre- and post-decrement, the object is said to be *decrementable*.

4 Let `a` and `b` be equal objects of type `I`. `I` models *decrementable* only if

(4.1) — If `a` and `b` are decrementable, then the following are all true:

(4.1.1) — `addressof(--a) == addressof(a)`

(4.1.2) — `bool(a-- == b)`

(4.1.3) — `bool(((void)a--, a) == --b)`

(4.1.4) — `bool(++(--a) == b)`.

(4.2) — If `a` and `b` are incrementable, then `bool(--(++a) == b)`.

5 The exposition-only *`advanceable`* concept is equivalent to:

```
template<class I>
  concept advanceable =                    // exposition only
    decrementable<I> && totally_ordered<I> &&
    requires(I i, const I j, const IOTA-DIFF-T(I) n) {
      { i += n } -> same_as<I&>;
      { i -= n } -> same_as<I&>;
      I(j + n);
      I(n + j);
      I(j - n);
      { j - j } -> convertible_to<IOTA-DIFF-T(I)>;
    };
```

Let `D` be *`IOTA-DIFF-T`*`(I)`. Let `a` and `b` be objects of type `I` such that `b` is reachable from `a` after `n` applications of `++a`, for some value `n` of type `D`. `I` models *`advanceable`* only if

(5.1) — `(a += n)` is equal to `b`.

(5.2) — `addressof(a += n)` is equal to `addressof(a)`.

(5.3) — `I(a + n)` is equal to `(a += n)`.

(5.4) — For any two positive values `x` and `y` of type `D`, if `I(a + D(x + y))` is well-defined, then `I(a + D(x + y))` is equal to `I(I(a + x) + y)`.

(5.5) — `I(a + D(0))` is equal to `a`.

(5.6) — If `I(a + D(n - 1))` is well-defined, then `I(a + n)` is equal to `[](I c) { return ++c; }(I(a + D(n - 1)))`.

(5.7) — `(b += -n)` is equal to `a`.

(5.8) — `(b -= n)` is equal to `a`.

(5.9) — `addressof(b -= n)` is equal to `addressof(b)`.

(5.10) — `I(b - n)` is equal to `(b -= n)`.

(5.11) — `D(b - a)` is equal to `n`.

(5.12) — `D(a - b)` is equal to `D(-n)`.

(5.13) — `bool(a <= b)` is `true`.

```
constexpr explicit iota_view(W value);
```

6 *Preconditions*: `Bound` denotes `unreachable_sentinel_t` or `Bound()` is reachable from `value`. When `W` and `Bound` model `totally_ordered_with`, then `bool(value <= Bound())` is `true`.

7 *Effects*: Initializes *`value_`* with `value`.

```
constexpr explicit iota_view(type_identity_t<W> value, type_identity_t<Bound> bound);
```

8 *Preconditions*: `Bound` denotes `unreachable_sentinel_t` or `bound` is reachable from `value`. When `W` and `Bound` model `totally_ordered_with`, then `bool(value <= bound)` is `true`.

9 *Effects*: Initializes *`value_`* with `value` and *`bound_`* with `bound`.

```
constexpr explicit iota_view(iterator first, see below last);
```

10 *Effects*: Equivalent to:

(10.1) — If `same_as<W, Bound>` is `true`, `iota_view(first.`*`value_`*`, last.`*`value_`*`)`.

(10.2) — Otherwise, if `Bound` denotes `unreachable_sentinel_t`, `iota_view(first.`*`value_`*`, last)`.

(10.3) — Otherwise, `iota_view(first.`*`value_`*`, last.`*`bound_`*`)`.

11 *Remarks*: The type of `last` is:

(11.1) — If `same_as<W, Bound>` is `true`, *`iterator`*.

(11.2) — Otherwise, if `Bound` denotes `unreachable_sentinel_t`, `Bound`.

(11.3) — Otherwise, *`sentinel`*.

```
constexpr iterator begin() const;
```

12 *Effects*: Equivalent to: `return iterator{value_};`

```
constexpr auto end() const;
```

13 *Effects*: Equivalent to:

```
if constexpr (same_as<Bound, unreachable_sentinel_t>)
  return unreachable_sentinel;
else
  return sentinel{bound_};
```

```
constexpr iterator end() const requires same_as<W, Bound>;
```

14 *Effects*: Equivalent to: `return iterator{bound_};`

```
constexpr bool empty() const;
```

15 *Effects*: Equivalent to: `return value_ == bound_;`

```
constexpr auto size() const requires see below;
```

16 *Effects*: Equivalent to:

```
if constexpr (is-integer-like<W> && is-integer-like<Bound>)
  return (value_ < 0)
    ? ((bound_ < 0)
      ? to-unsigned-like(-value_) - to-unsigned-like(-bound_)
      : to-unsigned-like(bound_) + to-unsigned-like(-value_))
    : to-unsigned-like(bound_) - to-unsigned-like(value_);
else
  return to-unsigned-like(bound_ - value_);
```

17 *Remarks*: The expression in the *requires-clause* is equivalent to:

```
(same_as<W, Bound> && advanceable<W>) || (is-integer-like<W> && is-integer-like<Bound>) ||
  sized_sentinel_for<Bound, W>
```

25.6.4.3 Class `iota_view::iterator` [range.iota.iterator]

```
namespace std::ranges {
  template<weakly_incrementable W, semiregular Bound>
    requires weakly-equality-comparable-with<W, Bound> && copyable<W>
  struct iota_view<W, Bound>::iterator {
  private:

```
friend constexpr iter_difference_t<W> operator-(const sentinel& x, const iterator& y)
  requires sized_sentinel_for<Bound, W>;
```

4 *Effects*: Equivalent to: `return -(y - x);`

25.6.5 Repeat view [range.repeat]

25.6.5.1 Overview [range.repeat.overview]

1 `repeat_view` generates a sequence of elements by repeatedly producing the same value.

2 The name `views::repeat` denotes a customization point object (16.3.3.3.5). Given subexpressions `E` and `F`, the expressions `views::repeat(E)` and `views::repeat(E, F)` are expression-equivalent to `repeat_view<decay_t<decltype((E))>>(E)` and `repeat_view(E, F)`, respectively.

3 [*Example 1*:

```
for (int i : views::repeat(17, 4))
  cout << i << ' ';
// prints 17 17 17 17
```

— *end example*]

25.6.5.2 Class template `repeat_view` [range.repeat.view]

```
namespace std::ranges {
  template<class T>
    concept integer-like-with-usable-difference-type =  // exposition only
      is-signed-integer-like<T> || (is-integer-like<T> && weakly_incrementable<T>);

  template<move_constructible T, semiregular Bound = unreachable_sentinel_t>
    requires (is_object_v<T> && same_as<T, remove_cv_t<T>> &&
              (integer-like-with-usable-difference-type<Bound> ||
               same_as<Bound, unreachable_sentinel_t>))
  class repeat_view : public view_interface<repeat_view<T, Bound>> {
  private:
    // 25.6.5.3, class repeat_view::iterator
    struct iterator;                              // exposition only

    movable-box<T> value_;                        // exposition only, see 25.7.3
    Bound bound_ = Bound();                       // exposition only

  public:
    repeat_view() requires default_initializable<T> = default;

    constexpr explicit repeat_view(const T& value, Bound bound = Bound())
      requires copy_constructible<T>;
    constexpr explicit repeat_view(T&& value, Bound bound = Bound());
    template<class... TArgs, class... BoundArgs>
      requires constructible_from<T, TArgs...> &&
               constructible_from<Bound, BoundArgs...>
    constexpr explicit repeat_view(piecewise_construct_t,
      tuple<TArgs...> value_args, tuple<BoundArgs...> bound_args = tuple<>{});

    constexpr iterator begin() const;
    constexpr iterator end() const requires (!same_as<Bound, unreachable_sentinel_t>);
    constexpr unreachable_sentinel_t end() const noexcept;
```

```
    constexpr auto size() const requires (!same_as<Bound, unreachable_sentinel_t>);
  };

  template<class T, class Bound = unreachable_sentinel_t>
    repeat_view(T, Bound = Bound()) -> repeat_view<T, Bound>;
}
```

```
constexpr explicit repeat_view(const T& value, Bound bound = Bound())
  requires copy_constructible<T>;
```

1 *Preconditions*: If `Bound` is not `unreachable_sentinel_t`, `bound` ≥ 0.

2 *Effects*: Initializes *`value_`* with `value` and *`bound_`* with `bound`.

```
constexpr explicit repeat_view(T&& value, Bound bound = Bound());
```

3 *Preconditions*: If `Bound` is not `unreachable_sentinel_t`, `bound` ≥ 0.

4 *Effects*: Initializes *`value_`* with `std::move(value)` and *`bound_`* with `bound`.

```
template<class... TArgs, class... BoundArgs>
  requires constructible_from<T, TArgs...> &&
           constructible_from<Bound, BoundArgs...>
constexpr explicit repeat_view(piecewise_construct_t,
  tuple<TArgs...> value_args, tuple<BoundArgs...> bound_args = tuple<>{});
```

5 *Effects*: Initializes *`value_`* with `make_from_tuple<T>(std::move(value_args))` and initializes *`bound_`* with `make_from_tuple<Bound>(std::move(bound_args))`. The behavior is undefined if `Bound` is not `unreachable_sentinel_t` and *`bound_`* is negative.

```
constexpr iterator begin() const;
```

6 *Effects*: Equivalent to: `return iterator(addressof(*value_));`

```
constexpr iterator end() const requires (!same_as<Bound, unreachable_sentinel_t>);
```

7 *Effects*: Equivalent to: `return iterator(addressof(*value_), bound_);`

```
constexpr unreachable_sentinel_t end() const noexcept;
```

8 *Effects*: Equivalent to: `return unreachable_sentinel;`

```
constexpr auto size() const requires (!same_as<Bound, unreachable_sentinel_t>);
```

9 *Effects*: Equivalent to: `return to-unsigned-like(bound_);`

25.6.5.3 Class `repeat_view::iterator` [range.repeat.iterator]

```
namespace std::ranges {
  template<move_constructible T, semiregular Bound>
    requires (is_object_v<T> && same_as<T, remove_cv_t<T>> &&
              (integer-like-with-usable-difference-type<Bound> ||
               same_as<Bound, unreachable_sentinel_t>))
  class repeat_view<T, Bound>::iterator {
  private:
    using index-type =                              // exposition only
      conditional_t<same_as<Bound, unreachable_sentinel_t>, ptrdiff_t, Bound>;

```

7 *Preconditions*: If `Bound` is not `unreachable_sentinel_t`, *current_* > 0.

8 *Effects*: Equivalent to:

```
--current_;
return *this;
```

```
constexpr iterator operator--(int);
```

9 *Effects*: Equivalent to:

```
auto tmp = *this;
--*this;
return tmp;
```

```
constexpr iterator& operator+=(difference_type n);
```

10 *Preconditions*: If `Bound` is not `unreachable_sentinel_t`, *current_* + `n` ≥ 0.

11 *Effects*: Equivalent to:

```
current_ += n;
return *this;
```

©ISO/IEC

```
constexpr iterator& operator-=(difference_type n);
```

12 *Preconditions*: If `Bound` is not `unreachable_sentinel_t`, $current\_ - n \geq 0$.

13 *Effects*: Equivalent to:

```
current_ -= n;
return *this;
```

```
constexpr const T& operator[](difference_type n) const noexcept;
```

14 *Effects*: Equivalent to: `return *(*this + n);`

```
friend constexpr bool operator==(const iterator& x, const iterator& y);
```

15 *Effects*: Equivalent to: `return x.current_ == y.current_;`

```
friend constexpr auto operator<=>(const iterator& x, const iterator& y);
```

16 *Effects*: Equivalent to: `return x.current_ <=> y.current_;`

```
friend constexpr iterator operator+(iterator i, difference_type n);
friend constexpr iterator operator+(difference_type n, iterator i);
```

17 *Effects*: Equivalent to:

```
i += n;
return i;
```

```
friend constexpr iterator operator-(iterator i, difference_type n);
```

18 *Effects*: Equivalent to:

```
i -= n;
return i;
```

```
friend constexpr difference_type operator-(const iterator& x, const iterator& y);
```

19 *Effects*: Equivalent to:

```
return static_cast<difference_type>(x.current_) - static_cast<difference_type>(y.current_);
```

25.6.6 Istream view [range.istream]

25.6.6.1 Overview [range.istream.overview]

1 `basic_istream_view` models `input_range` and reads (using `operator>>`) successive elements from its corresponding input stream.

2 The name `views::istream<T>` denotes a customization point object (16.3.3.3.5). Given a type `T` and a subexpression `E` of type `U`, if `U` models `derived_from<basic_istream<typename U::char_type, typename U::traits_type>>`, then the expression `views::istream<T>(E)` is expression-equivalent to `basic_istream_view<T, typename U::char_type, typename U::traits_type>(E)`; otherwise, `views::istream<T>(E)` is ill-formed.

3 [*Example 1*:

```
auto ints = istringstream{"0 1  2   3     4"};
ranges::copy(views::istream<int>(ints), ostream_iterator<int>{cout, "-"});
// prints 0-1-2-3-4-
```

— *end example*]

25.6.6.2 Class template `basic_istream_view` [range.istream.view]

```
namespace std::ranges {
  template<class Val, class CharT, class Traits>
    concept stream-extractable =                // exposition only
      requires(basic_istream<CharT, Traits>& is, Val& t) {
        is >> t;
      };
```

```
  template<movable Val, class CharT, class Traits = char_traits<CharT>>
    requires default_initializable<Val> &&
             stream-extractable<Val, CharT, Traits>
  class basic_istream_view : public view_interface<basic_istream_view<Val, CharT, Traits>> {
  public:
    constexpr explicit basic_istream_view(basic_istream<CharT, Traits>& stream);

    constexpr auto begin() {
      *stream_ >> value_;
      return iterator{*this};
    }

    constexpr default_sentinel_t end() const noexcept;

  private:
    // 25.6.6.3, class basic_istream_view::iterator
    struct iterator;                              // exposition only
    basic_istream<CharT, Traits>* stream_;        // exposition only
    Val value_ = Val();                           // exposition only
  };
}
```

```
constexpr explicit basic_istream_view(basic_istream<CharT, Traits>& stream);
```

1 *Effects*: Initializes *stream_* with `addressof(stream)`.

```
constexpr default_sentinel_t end() const noexcept;
```

2 *Effects*: Equivalent to: `return default_sentinel;`

25.6.6.3 Class `basic_istream_view::iterator` [range.istream.iterator]

```
namespace std::ranges {
  template<movable Val, class CharT, class Traits>
    requires default_initializable<Val> &&
             stream-extractable<Val, CharT, Traits>
  class basic_istream_view<Val, CharT, Traits>::iterator {
  public:
    using iterator_concept = input_iterator_tag;
    using difference_type = ptrdiff_t;
    using value_type = Val;

    iterator(const iterator&) = delete;
    iterator(iterator&&) = default;

    iterator& operator=(const iterator&) = delete;
    iterator& operator=(iterator&&) = default;

    iterator& operator++();
    void operator++(int);

    Val& operator*() const;

    friend bool operator==(const iterator& x, default_sentinel_t);

  private:
    constexpr explicit iterator(basic_istream_view& parent) noexcept;   // exposition only
    basic_istream_view* parent_;                                        // exposition only
  };
}
```

```
constexpr explicit iterator(basic_istream_view& parent) noexcept;
```

1 *Effects*: Initializes *parent_* with `addressof(parent)`.

```
iterator& operator++();
```

2 *Effects*: Equivalent to:

```
        *parent_->stream_ >> parent_->value_;
        return *this;
```

```
void operator++(int);
```

3 *Effects*: Equivalent to `++*this`.

```
Val& operator*() const;
```

4 *Effects*: Equivalent to: `return parent_->value_;`

```
friend bool operator==(const iterator& x, default_sentinel_t);
```

5 *Effects*: Equivalent to: `return !*x.parent_->stream_;`

25.7 Range adaptors [range.adaptors]

25.7.1 General [range.adaptors.general]

1 Subclause 25.7 defines *range adaptors*, which are utilities that transform a range into a view with custom behaviors. These adaptors can be chained to create pipelines of range transformations that evaluate lazily as the resulting view is iterated.

2 Range adaptors are declared in namespace `std::ranges::views`.

3 The bitwise OR operator is overloaded for the purpose of creating adaptor chain pipelines. The adaptors also support function call syntax with equivalent semantics.

4 [*Example 1*:

```
vector<int> ints{0,1,2,3,4,5};
auto even = [](int i) { return 0 == i % 2; };
auto square = [](int i) { return i * i; };
for (int i : ints | views::filter(even) | views::transform(square)) {
  cout << i << ' '; // prints 0 4 16
}
assert(ranges::equal(ints | views::filter(even), views::filter(ints, even)));
```

— *end example*]

25.7.2 Range adaptor objects [range.adaptor.object]

1 A *range adaptor closure object* is a unary function object that accepts a range argument. For a range adaptor closure object `C` and an expression `R` such that `decltype((R))` models `range`, the following expressions are equivalent:

```
C(R)
R | C
```

Given an additional range adaptor closure object `D`, the expression `C | D` produces another range adaptor closure object `E`. `E` is a perfect forwarding call wrapper (22.10.4) with the following properties:

(1.1) — Its target object is an object `d` of type `decay_t<decltype((D))>` direct-non-list-initialized with `D`.

(1.2) — It has one bound argument entity, an object `c` of type `decay_t<decltype((C))>` direct-non-list-initialized with `C`.

(1.3) — Its call pattern is `d(c(arg))`, where `arg` is the argument used in a function call expression of `E`.

The expression `C | D` is well-formed if and only if the initializations of the state entities of `E` are all well-formed.

2 Given an object `t` of type `T`, where

(2.1) — `t` is a unary function object that accepts a range argument,

(2.2) — `T` models `derived_from<range_adaptor_closure<T>>`,

(2.3) — `T` has no other base classes of type `range_adaptor_closure<U>` for any other type `U`, and

(2.4) — `T` does not model `range`

then the implementation ensures that `t` is a range adaptor closure object.

3 The template parameter `D` for `range_adaptor_closure` may be an incomplete type. If an expression of type *cv* `D` is used as an operand to the `|` operator, `D` shall be complete and model `derived_from<range_adaptor_closure<D>>`. The behavior of an expression involving an object of type *cv* `D` as an operand to the `|` operator is undefined if overload resolution selects a program-defined `operator|` function.

4 If an expression of type *cv* `U` is used as an operand to the `|` operator, where `U` has a base class of type `range_adaptor_closure<T>` for some type `T` other than `U`, the behavior is undefined.

5 The behavior of a program that adds a specialization for `range_adaptor_closure` is undefined.

6 A *range adaptor object* is a customization point object (16.3.3.3.5) that accepts a `viewable_range` as its first argument and returns a view.

7 If a range adaptor object accepts only one argument, then it is a range adaptor closure object.

8 If a range adaptor object `adaptor` accepts more than one argument, then let `range` be an expression such that `decltype((range))` models `viewable_range`, let `args...` be arguments such that `adaptor(range, args...)` is a well-formed expression as specified in the rest of subclause 25.7, and let `BoundArgs` be a pack that denotes `decay_t<decltype((args))>...`. The expression `adaptor(args...)` produces a range adaptor closure object `f` that is a perfect forwarding call wrapper (22.10.4) with the following properties:

(8.1) — Its target object is a copy of `adaptor`.

(8.2) — Its bound argument entities `bound_args` consist of objects of types `BoundArgs...` direct-non-list-initialized with `std::forward<decltype((args))>(args)...`, respectively.

(8.3) — Its call pattern is `adaptor(r, bound_args...)`, where `r` is the argument used in a function call expression of `f`.

The expression `adaptor(args...)` is well-formed if and only if the initialization of the bound argument entities of the result, as specified above, are all well-formed.

25.7.3 Movable wrapper [range.move.wrap]

1 Many types in this subclause are specified in terms of an exposition-only class template *`movable-box`*. *`movable-box`*`<T>` behaves exactly like `optional<T>` with the following differences:

(1.1) — *`movable-box`*`<T>` constrains its type parameter `T` with `move_constructible<T> && is_object_v<T>`.

(1.2) — The default constructor of *`movable-box`*`<T>` is equivalent to:

```
constexpr movable-box() noexcept(is_nothrow_default_constructible_v<T>)
    requires default_initializable<T>
  : movable-box{in_place} {}
```

(1.3) — If `copyable<T>` is not modeled, the copy assignment operator is equivalent to:

```
constexpr movable-box& operator=(const movable-box& that)
  noexcept(is_nothrow_copy_constructible_v<T>)
  requires copy_constructible<T> {
  if (this != addressof(that)) {
    if (that) emplace(*that);
    else reset();
  }
  return *this;
}
```

(1.4) — If `movable<T>` is not modeled, the move assignment operator is equivalent to:

```
constexpr movable-box& operator=(movable-box&& that)
  noexcept(is_nothrow_move_constructible_v<T>) {
  if (this != addressof(that)) {
    if (that) emplace(std::move(*that));
    else reset();
  }
  return *this;
}
```

2 *Recommended practice*:

(2.1) — If `copy_constructible<T>` is `true`, *`movable-box`*`<T>` should store only a `T` if either `T` models `copyable`, or `is_nothrow_move_constructible_v<T> && is_nothrow_copy_constructible_v<T>` is `true`.

(2.2) — Otherwise, *`movable-box`*`<T>` should store only a `T` if either `T` models `movable` or `is_nothrow_move_constructible_v<T>` is `true`.

25.7.4 Non-propagating cache [range.nonprop.cache]

1 Some types in 25.7 are specified in terms of an exposition-only class template *non-propagating-cache*. *non-propagating-cache*<T> behaves exactly like optional<T> with the following differences:

(1.1) — *non-propagating-cache*<T> constrains its type parameter T with is_object_v<T>.

(1.2) — The copy constructor is equivalent to:

```
constexpr non-propagating-cache(const non-propagating-cache&) noexcept {}
```

(1.3) — The move constructor is equivalent to:

```
constexpr non-propagating-cache(non-propagating-cache&& other) noexcept {
  other.reset();
}
```

(1.4) — The copy assignment operator is equivalent to:

```
constexpr non-propagating-cache& operator=(const non-propagating-cache& other) noexcept {
  if (addressof(other) != this)
    reset();
  return *this;
}
```

(1.5) — The move assignment operator is equivalent to:

```
constexpr non-propagating-cache& operator=(non-propagating-cache&& other) noexcept {
  reset();
  other.reset();
  return *this;
}
```

(1.6) — *non-propagating-cache*<T> has an additional member function template specified as follows:

```
template<class I>
  constexpr T& emplace-deref(const I& i);     // exposition only
```

Mandates: The declaration `T t(*i);` is well-formed for some invented variable `t`.

[*Note 1*: If `*i` is a prvalue of type *cv* `T`, there is no requirement that it is movable (9.5.1). — *end note*]

Effects: Calls `reset()`. Then direct-non-list-initializes the contained value with `*i`.

Postconditions: `*this` contains a value.

Returns: A reference to the new contained value.

Throws: Any exception thrown by the initialization of the contained value.

Remarks: If an exception is thrown during the initialization of `T`, `*this` does not contain a value, and the previous value (if any) has been destroyed.

2 [*Note 2*: *non-propagating-cache* enables an input view to temporarily cache values as it is iterated over. — *end note*]

25.7.5 Range adaptor helpers [range.adaptor.helpers]

```
namespace std::ranges {
  template<class F, class Tuple>
  constexpr auto tuple-transform(F&& f, Tuple&& t) { // exposition only
    return apply([&]<class... Ts>(Ts&&... elements) {
      return tuple<invoke_result_t<F&, Ts>...>(invoke(f, std::forward<Ts>(elements))...);
    }, std::forward<Tuple>(t));
  }

  template<class F, class Tuple>
  constexpr void tuple-for-each(F&& f, Tuple&& t) { // exposition only
    apply([&]<class... Ts>(Ts&&... elements) {
      (static_cast<void>(invoke(f, std::forward<Ts>(elements))), ...);
    }, std::forward<Tuple>(t));
  }
```

©ISO/IEC

```
  template<class T>
  constexpr T& as-lvalue(T&& t) {                    // exposition only
    return static_cast<T&>(t);
  }

  template<bool Const, class... Views>
    concept all-random-access =                      // exposition only
      (random_access_range<maybe-const<Const, Views>> && ...);
  template<bool Const, class... Views>
    concept all-bidirectional =                      // exposition only
      (bidirectional_range<maybe-const<Const, Views>> && ...);
  template<bool Const, class... Views>
    concept all-forward =                            // exposition only
      (forward_range<maybe-const<Const, Views>> && ...);
}
```

25.7.6 All view [range.all]

25.7.6.1 General [range.all.general]

1 `views::all` returns a view that includes all elements of its range argument.

2 The name `views::all` denotes a range adaptor object (25.7.2). Given a subexpression `E`, the expression `views::all(E)` is expression-equivalent to:

(2.1) — *decay-copy*`(E)` if the decayed type of `E` models `view`.

(2.2) — Otherwise, `ref_view{E}` if that expression is well-formed.

(2.3) — Otherwise, `owning_view{E}`.

25.7.6.2 Class template `ref_view` [range.ref.view]

1 `ref_view` is a view of the elements of some other range.

```
namespace std::ranges {
  template<range R>
    requires is_object_v<R>
  class ref_view : public view_interface<ref_view<R>> {
  private:
    R* r_;                          // exposition only

  public:
    template<different-from<ref_view> T>
      requires see below
    constexpr ref_view(T&& t);

    constexpr R& base() const { return *r_; }

    constexpr iterator_t<R> begin() const { return ranges::begin(*r_); }
    constexpr sentinel_t<R> end() const { return ranges::end(*r_); }

    constexpr bool empty() const
      requires requires { ranges::empty(*r_); }
    { return ranges::empty(*r_); }

    constexpr auto size() const requires sized_range<R>
    { return ranges::size(*r_); }

    constexpr auto reserve_hint() const requires approximately_sized_range<R>
    { return ranges::reserve_hint(*r_); }

    constexpr auto data() const requires contiguous_range<R>
    { return ranges::data(*r_); }
  };
```

```
    template<class R>
      ref_view(R&) -> ref_view<R>;
  }

template<different-from<ref_view> T>
  requires see below
constexpr ref_view(T&& t);
```

2 *Effects*: Initializes *r_* with `addressof(static_cast<R&>(std::forward<T>(t)))`.

3 *Remarks*: Let *FUN* denote the exposition-only functions

```
void FUN(R&);
void FUN(R&&) = delete;
```

The expression in the *requires-clause* is equivalent to:

```
convertible_to<T, R&> && requires { FUN(declval<T>()); }
```

25.7.6.3 Class template `owning_view` [range.owning.view]

1 `owning_view` is a move-only view of the elements of some other range.

```
namespace std::ranges {
  template<range R>
    requires movable<R> && (!is-initializer-list<R>) // see 25.4.6
  class owning_view : public view_interface<owning_view<R>> {
  private:
    R r_ = R();          // exposition only

  public:
    owning_view() requires default_initializable<R> = default;
    constexpr owning_view(R&& t);

    owning_view(owning_view&&) = default;
    owning_view& operator=(owning_view&&) = default;

    constexpr R& base() & noexcept { return r_; }
    constexpr const R& base() const & noexcept { return r_; }
    constexpr R&& base() && noexcept { return std::move(r_); }
    constexpr const R&& base() const && noexcept { return std::move(r_); }

    constexpr iterator_t<R> begin() { return ranges::begin(r_); }
    constexpr sentinel_t<R> end() { return ranges::end(r_); }

    constexpr auto begin() const requires range<const R>
    { return ranges::begin(r_); }
    constexpr auto end() const requires range<const R>
    { return ranges::end(r_); }

    constexpr bool empty() requires requires { ranges::empty(r_); }
    { return ranges::empty(r_); }
    constexpr bool empty() const requires requires { ranges::empty(r_); }
    { return ranges::empty(r_); }

    constexpr auto size() requires sized_range<R>
    { return ranges::size(r_); }
    constexpr auto size() const requires sized_range<const R>
    { return ranges::size(r_); }

    constexpr auto reserve_hint() requires approximately_sized_range<R>
    { return ranges::reserve_hint(r_); }
    constexpr auto reserve_hint() const requires approximately_sized_range<const R>
    { return ranges::reserve_hint(r_); }

    constexpr auto data() requires contiguous_range<R>
    { return ranges::data(r_); }
```

```
    constexpr auto data() const requires contiguous_range<const R>
    { return ranges::data(r_); }
  };
}

constexpr owning_view(R&& t);
```

2 *Effects*: Initializes `r_` with `std::move(t)`.

25.7.7 As rvalue view [range.as.rvalue]

25.7.7.1 Overview [range.as.rvalue.overview]

1 `as_rvalue_view` presents a view of an underlying sequence with the same behavior as the underlying sequence except that its elements are rvalues. Some generic algorithms can be called with an `as_rvalue_view` to replace copying with moving.

2 The name `views::as_rvalue` denotes a range adaptor object (25.7.2). Let `E` be an expression and let `T` be `decltype((E))`. The expression `views::as_rvalue(E)` is expression-equivalent to:

(2.1) — `views::all(E)` if `T` models `input_range` and `same_as<range_rvalue_reference_t<T>, range_reference_t<T>>` is `true`.

(2.2) — Otherwise, `as_rvalue_view(E)`.

3 [*Example 1*:

```
vector<string> words = {"the", "quick", "brown", "fox", "ate", "a", "pterodactyl"};
vector<string> new_words;
ranges::copy(words | views::as_rvalue, back_inserter(new_words));
  // moves each string from words into new_words
```

— *end example*]

25.7.7.2 Class template `as_rvalue_view` [range.as.rvalue.view]

```
namespace std::ranges {
  template<view V>
    requires input_range<V>
  class as_rvalue_view : public view_interface<as_rvalue_view<V>> {
    V base_ = V();      // exposition only

  public:
    as_rvalue_view() requires default_initializable<V> = default;
    constexpr explicit as_rvalue_view(V base);

    constexpr V base() const & requires copy_constructible<V> { return base_; }
    constexpr V base() && { return std::move(base_); }

    constexpr auto begin() requires (!simple-view<V>)
    { return move_iterator(ranges::begin(base_)); }
    constexpr auto begin() const requires range<const V>
    { return move_iterator(ranges::begin(base_)); }

    constexpr auto end() requires (!simple-view<V>) {
      if constexpr (common_range<V>) {
        return move_iterator(ranges::end(base_));
      } else {
        return move_sentinel(ranges::end(base_));
      }
    }
    constexpr auto end() const requires range<const V> {
      if constexpr (common_range<const V>) {
        return move_iterator(ranges::end(base_));
      } else {
        return move_sentinel(ranges::end(base_));
      }
    }
```

©ISO/IEC

```
    constexpr auto size() requires sized_range<V> { return ranges::size(base_); }
    constexpr auto size() const requires sized_range<const V> { return ranges::size(base_); }

    constexpr auto reserve_hint() requires approximately_sized_range<V>
    { return ranges::reserve_hint(base_); }
    constexpr auto reserve_hint() const requires approximately_sized_range<const V>
    { return ranges::reserve_hint(base_); }
  };

  template<class R>
    as_rvalue_view(R&&) -> as_rvalue_view<views::all_t<R>>;
}

constexpr explicit as_rvalue_view(V base);
```

1 *Effects*: Initializes *base_* with `std::move(base)`.

25.7.8 Filter view [range.filter]

25.7.8.1 Overview [range.filter.overview]

1 `filter_view` presents a view of the elements of an underlying sequence that satisfy a predicate.

2 The name `views::filter` denotes a range adaptor object (25.7.2). Given subexpressions `E` and `P`, the expression `views::filter(E, P)` is expression-equivalent to `filter_view(E, P)`.

3 [*Example 1*:

```
vector<int> is{ 0, 1, 2, 3, 4, 5, 6 };
auto evens = views::filter(is, [](int i) { return 0 == i % 2; });
for (int i : evens)
  cout << i << ' '; // prints 0 2 4 6
```

— *end example*]

25.7.8.2 Class template `filter_view` [range.filter.view]

```
namespace std::ranges {
  template<input_range V, indirect_unary_predicate<iterator_t<V>> Pred>
    requires view<V> && is_object_v<Pred>
  class filter_view : public view_interface<filter_view<V, Pred>> {
  private:
    V base_ = V();                                  // exposition only
    movable-box<Pred> pred_;                        // exposition only

    // 25.7.8.3, class filter_view::iterator
    template<bool> class iterator;                  // exposition only

    // 25.7.8.4, class filter_view::sentinel
    template<bool> class sentinel;                  // exposition only

  public:
    filter_view() requires default_initializable<V> && default_initializable<Pred> = default;
    constexpr explicit filter_view(V base, Pred pred);

    constexpr V base() const & requires copy_constructible<V> { return base_; }
    constexpr V base() && { return std::move(base_); }

    constexpr const Pred& pred() const;

    constexpr iterator<false> begin();
    constexpr iterator<true> begin() const
      requires (input_range<const V> && !forward_range<const V> &&
                indirect_unary_predicate<const Pred, iterator_t<const V>>);

    constexpr auto end() {
      if constexpr (common_range<V>)
        return iterator<false>{*this, ranges::end(base_)};
```

```
      else
        return sentinel<false>{*this};
    }
    constexpr sentinel<true> end() const
      requires (input_range<const V> && !forward_range<const V> &&
                indirect_unary_predicate<const Pred, iterator_t<const V>>) {
      return sentinel<true>{*this};
    }
  };

  template<class R, class Pred>
    filter_view(R&&, Pred) -> filter_view<views::all_t<R>, Pred>;
}
```

```
constexpr explicit filter_view(V base, Pred pred);
```

1 *Effects*: Initializes *base_* with `std::move(base)` and initializes *pred_* with `std::move(pred)`.

```
constexpr const Pred& pred() const;
```

2 *Effects*: Equivalent to: `return *pred_;`

```
constexpr iterator<false> begin();
```

3 *Preconditions*: *pred_*`.has_value()` is `true`.

4 *Returns*: `{*this, ranges::find_if(`*base_*`, ref(*`*pred_*`))}`.

5 *Remarks*: In order to provide the amortized constant time complexity required by the `range` concept when `filter_view` models `forward_range`, this function caches the result within the `filter_view` for use on subsequent calls.

```
constexpr iterator<true> begin() const
  requires (input_range<const V> && !forward_range<const V> &&
            indirect_unary_predicate<const Pred, iterator_t<const V>>);
```

6 *Preconditions*: *pred_*`.has_value()` is `true`.

7 *Returns*: `{*this, ranges::find_if(`*base_*`, ref(*`*pred_*`))}`.

[*Note 1*: This function does not cache the result within the `filter_view`. — *end note*]

25.7.8.3 Class template `filter_view::`*iterator* [range.filter.iterator]

```
namespace std::ranges {
  template<input_range V, indirect_unary_predicate<iterator_t<V>> Pred>
    requires view<V> && is_object_v<Pred>
  template<bool Const>
  class filter_view<V, Pred>::iterator {
  private:
    using Parent = maybe-const<Const, filter_view>;                    // exposition only
    using Base = maybe-const<Const, V>;                                // exposition only
    iterator_t<Base> current_ = iterator_t<Base>();                    // exposition only
    Parent* parent_ = nullptr;                                         // exposition only
    constexpr iterator(Parent& parent, iterator_t<Base> current);      // exposition only

  public:
    using iterator_concept  = see below;
    using iterator_category = see below;                               // not always present
    using value_type        = range_value_t<Base>;
    using difference_type   = range_difference_t<Base>;

    iterator() requires default_initializable<iterator_t<Base>> = default;
    constexpr iterator(iterator<!Const> i)
      requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;

    constexpr const iterator_t<Base>& base() const & noexcept;
    constexpr iterator_t<Base> base() &&;
    constexpr range_reference_t<Base> operator*() const;
```

```
    constexpr iterator_t<Base> operator->() const
      requires has-arrow<iterator_t<Base>> && copyable<iterator_t<Base>>;

    constexpr iterator& operator++();
    constexpr void operator++(int);
    constexpr iterator operator++(int) requires forward_range<Base>;

    constexpr iterator& operator--() requires bidirectional_range<Base>;
    constexpr iterator operator--(int) requires bidirectional_range<Base>;

    friend constexpr bool operator==(const iterator& x, const iterator& y)
      requires equality_comparable<iterator_t<Base>>;

    friend constexpr range_rvalue_reference_t<Base> iter_move(const iterator& i)
      noexcept(noexcept(ranges::iter_move(i.current_)));

    friend constexpr void iter_swap(const iterator& x, const iterator& y)
      noexcept(noexcept(ranges::iter_swap(x.current_, y.current_)))
      requires indirectly_swappable<iterator_t<Base>>;
  };
}
```

1 [*Note 1*: Modification of the element a `filter_view::`*`iterator`* denotes can result in undefined behavior if the underlying range is a `forward_range` and the resulting value does not satisfy the filter predicate when the predicate is next evaluated for that element (18.2). — *end note*]

2 *`iterator`*`::iterator_concept` is defined as follows:

(2.1) — If `Const` is `true`, then `iterator_concept` denotes `input_iterator_tag`.

(2.2) — Otherwise, if `V` models `bidirectional_range`, then `iterator_concept` denotes `bidirectional_iterator_tag`.

(2.3) — Otherwise, if `V` models `forward_range`, then `iterator_concept` denotes `forward_iterator_tag`.

(2.4) — Otherwise, `iterator_concept` denotes `input_iterator_tag`.

3 The member *typedef-name* `iterator_category` is declared if and only if *`Base`* models `forward_range`. In that case, *`iterator`*`::iterator_category` is defined as follows:

(3.1) — Let `C` denote the type `iterator_traits<iterator_t<`*`Base`*`>>::iterator_category`.

(3.2) — If `C` models `derived_from<bidirectional_iterator_tag>`, then `iterator_category` denotes `bidirectional_iterator_tag`.

(3.3) — Otherwise, if `C` models `derived_from<forward_iterator_tag>`, then `iterator_category` denotes `forward_iterator_tag`.

(3.4) — Otherwise, `iterator_category` denotes `C`.

```
constexpr iterator(Parent& parent, iterator_t<Base> current);
```

4 *Effects*: Initializes *`current_`* with `std::move(current)` and *`parent_`* with `addressof(parent)`.

```
constexpr iterator(iterator<!Const> i)
  requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;
```

5 *Effects*: Initializes *`parent_`* with `i.`*`parent_`* and *`current_`* with `std::move(i.`*`current_`*`)`.

```
constexpr const iterator_t<Base>& base() const & noexcept;
```

6 *Effects*: Equivalent to: `return` *`current_`*`;`

```
constexpr iterator_t<Base> base() &&;
```

7 *Effects*: Equivalent to: `return std::move(`*`current_`*`);`

```
constexpr range_reference_t<Base> operator*() const;
```

8 *Effects*: Equivalent to: `return *`*`current_`*`;`

```
constexpr iterator_t<Base> operator->() const
  requires has-arrow<iterator_t<Base>> && copyable<iterator_t<Base>>;
```

9 *Effects*: Equivalent to: `return current_;`

```
constexpr iterator& operator++();
```

10 *Effects*: Equivalent to:

```
current_ = ranges::find_if(std::move(++current_), ranges::end(parent_->base_),
                           ref(*parent_->pred_));
return *this;
```

```
constexpr void operator++(int);
```

11 *Effects*: Equivalent to `++*this`.

```
constexpr iterator operator++(int) requires forward_range<Base>;
```

12 *Effects*: Equivalent to:

```
auto tmp = *this;
++*this;
return tmp;
```

```
constexpr iterator& operator--() requires bidirectional_range<Base>;
```

13 *Effects*: Equivalent to:

```
do
  --current_;
while (!invoke(*parent_->pred_, *current_));
return *this;
```

```
constexpr iterator operator--(int) requires bidirectional_range<Base>;
```

14 *Effects*: Equivalent to:

```
auto tmp = *this;
--*this;
return tmp;
```

```
friend constexpr bool operator==(const iterator& x, const iterator& y)
  requires equality_comparable<iterator_t<Base>>;
```

15 *Effects*: Equivalent to: `return x.current_ == y.current_;`

```
friend constexpr range_rvalue_reference_t<Base> iter_move(const iterator& i)
  noexcept(noexcept(ranges::iter_move(i.current_)));
```

16 *Effects*: Equivalent to: `return ranges::iter_move(i.current_);`

```
friend constexpr void iter_swap(const iterator& x, const iterator& y)
  noexcept(noexcept(ranges::iter_swap(x.current_, y.current_)))
  requires indirectly_swappable<iterator_t<Base>>;
```

17 *Effects*: Equivalent to `ranges::iter_swap(x.current_, y.current_)`.

25.7.8.4 Class template `filter_view::sentinel` [range.filter.sentinel]

```
namespace std::ranges {
  template<input_range V, indirect_unary_predicate<iterator_t<V>> Pred>
    requires view<V> && is_object_v<Pred>
  template<bool Const>
  class filter_view<V, Pred>::sentinel {
  private:
    using Base = maybe-const<Const, V>;                    // exposition only
    sentinel_t<Base> end_ = sentinel_t<Base>();            // exposition only
    constexpr explicit sentinel(Parent& parent);           // exposition only

  public:
    sentinel() = default;
    constexpr sentinel(sentinel<!Const> other)
      requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;
```

```
    constexpr sentinel_t<Base> base() const;

    template<bool OtherConst>
      requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
      friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);
  };
}

constexpr sentinel(sentinel<!Const> other)
  requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;
```

1 *Effects*: Initializes *end_* with `std::move(other.end_)`.

```
constexpr explicit sentinel(Parent& parent);
```

2 *Effects*: Initializes *end_* with `ranges::end(parent.base_)`.

```
constexpr sentinel_t<Base> base() const;
```

3 *Effects*: Equivalent to: `return end_;`

```
template<bool OtherConst>
  requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const <OtherConst, V>>>
  friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);
```

4 *Effects*: Equivalent to: `return x.current_ == y.end_;`

25.7.9 Transform view [range.transform]

25.7.9.1 Overview [range.transform.overview]

1 `transform_view` presents a view of an underlying sequence after applying a transformation function to each element.

2 The name `views::transform` denotes a range adaptor object (25.7.2). Given subexpressions `E` and `F`, the expression `views::transform(E, F)` is expression-equivalent to `transform_view(E, F)`.

3 [*Example 1*:

```
vector<int> is{ 0, 1, 2, 3, 4 };
auto squares = views::transform(is, [](int i) { return i * i; });
for (int i : squares)
  cout << i << ' '; // prints 0 1 4 9 16
```

— *end example*]

25.7.9.2 Class template `transform_view` [range.transform.view]

```
namespace std::ranges {
  template<input_range V, move_constructible F>
    requires view<V> && is_object_v<F> &&
             regular_invocable<F&, range_reference_t<V>> &&
             can-reference<invoke_result_t<F&, range_reference_t<V>>>
  class transform_view : public view_interface<transform_view<V, F>> {
  private:
    // 25.7.9.3, class template transform_view::iterator
    template<bool> struct iterator;              // exposition only

    // 25.7.9.4, class template transform_view::sentinel
    template<bool> struct sentinel;              // exposition only

    V base_ = V();                               // exposition only
    movable-box<F> fun_;                         // exposition only

  public:
    transform_view() requires default_initializable<V> && default_initializable<F> = default;
    constexpr explicit transform_view(V base, F fun);

    constexpr V base() const & requires copy_constructible<V> { return base_; }
    constexpr V base() && { return std::move(base_); }
```

```
    constexpr iterator<false> begin();
    constexpr iterator<true> begin() const
      requires range<const V> &&
               regular_invocable<const F&, range_reference_t<const V>>;

    constexpr sentinel<false> end();
    constexpr iterator<false> end() requires common_range<V>;
    constexpr sentinel<true> end() const
      requires range<const V> &&
               regular_invocable<const F&, range_reference_t<const V>>;
    constexpr iterator<true> end() const
      requires common_range<const V> &&
               regular_invocable<const F&, range_reference_t<const V>>;

    constexpr auto size() requires sized_range<V> { return ranges::size(base_); }
    constexpr auto size() const requires sized_range<const V>
    { return ranges::size(base_); }

    constexpr auto reserve_hint() requires approximately_sized_range<V>
    { return ranges::reserve_hint(base_); }
    constexpr auto reserve_hint() const requires approximately_sized_range<const V>
    { return ranges::reserve_hint(base_); }
  };

  template<class R, class F>
    transform_view(R&&, F) -> transform_view<views::all_t<R>, F>;
}
```

```
constexpr explicit transform_view(V base, F fun);
```

1 *Effects*: Initializes *base_* with `std::move(base)` and *fun_* with `std::move(fun)`.

```
constexpr iterator<false> begin();
```

2 *Effects*: Equivalent to:

```
return iterator<false>{*this, ranges::begin(base_)};
```

```
constexpr iterator<true> begin() const
  requires range<const V> &&
           regular_invocable<const F&, range_reference_t<const V>>;
```

3 *Effects*: Equivalent to:

```
return iterator<true>{*this, ranges::begin(base_)};
```

```
constexpr sentinel<false> end();
```

4 *Effects*: Equivalent to:

```
return sentinel<false>{ranges::end(base_)};
```

```
constexpr iterator<false> end() requires common_range<V>;
```

5 *Effects*: Equivalent to:

```
return iterator<false>{*this, ranges::end(base_)};
```

```
constexpr sentinel<true> end() const
  requires range<const V> &&
           regular_invocable<const F&, range_reference_t<const V>>;
```

6 *Effects*: Equivalent to:

```
return sentinel<true>{ranges::end(base_)};
```

```
constexpr iterator<true> end() const
  requires common_range<const V> &&
           regular_invocable<const F&, range_reference_t<const V>>;
```

7 *Effects*: Equivalent to:

```
return iterator<true>{*this, ranges::end(base_)};
```

25.7.9.3 Class template `transform_view::iterator` [range.transform.iterator]

```
namespace std::ranges {
  template<input_range V, move_constructible F>
    requires view<V> && is_object_v<F> &&
             regular_invocable<F&, range_reference_t<V>> &&
             can-reference<invoke_result_t<F&, range_reference_t<V>>>
  template<bool Const>
  class transform_view<V, F>::iterator {
  private:
    using Parent = maybe-const<Const, transform_view>;                  // exposition only

  requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;
```

2 *Effects*: Initializes *end_* with `std::move(i.end_)`.

```
constexpr sentinel_t<Base> base() const;
```

3 *Effects*: Equivalent to: `return end_;`

```
template<bool OtherConst>
  requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);
```

4 *Effects*: Equivalent to: `return x.current_ == y.end_;`

```
template<bool OtherConst>
  requires sized_sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
friend constexpr range_difference_t<maybe-const<OtherConst, V>>
  operator-(const iterator<OtherConst>& x, const sentinel& y);
```

5 *Effects*: Equivalent to: `return x.current_ - y.end_;`

```
template<bool OtherConst>
  requires sized_sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
friend constexpr range_difference_t<maybe-const<OtherConst, V>>
  operator-(const sentinel& y, const iterator<OtherConst>& x);
```

6 *Effects*: Equivalent to: `return y.end_ - x.current_;`

25.7.10 Take view [range.take]

25.7.10.1 Overview [range.take.overview]

1 `take_view` produces a view of the first N elements from another view, or all the elements if the adapted view contains fewer than N.

2 The name `views::take` denotes a range adaptor object (25.7.2). Let `E` and `F` be expressions, let `T` be `remove_cvref_t<decltype((E))>`, and let `D` be `range_difference_t<decltype((E))>`. If `decltype((F))` does not model `convertible_to<D>`, `views::take(E, F)` is ill-formed. Otherwise, the expression `views::take(E, F)` is expression-equivalent to:

(2.1) — If `T` is a specialization of `empty_view` (25.6.2.2), then `((void)F, decay-copy(E))`, except that the evaluations of `E` and `F` are indeterminately sequenced.

(2.2) — Otherwise, if `T` is a specialization of `optional` and `T` models `view`, then `(static_cast<D>(F) == D() ? ((void)E, T()) : decay-copy(E))`.

(2.3) — Otherwise, if `T` models `random_access_range` and `sized_range` and is a specialization of `span` (23.7.2.2), `basic_string_view` (27.3), or `subrange` (25.5.4), then `U(ranges::begin(E), ranges::begin(E) + std::min<D>(ranges::distance(E), F))`, except that `E` is evaluated only once, where `U` is a type determined as follows:

(2.3.1) — if `T` is a specialization of `span`, then `U` is `span<typename T::element_type>`;

(2.3.2) — otherwise, if `T` is a specialization of `basic_string_view`, then `U` is `T`;

(2.3.3) — otherwise, `T` is a specialization of `subrange`, and `U` is `subrange<iterator_t<T>>`;

(2.4) — otherwise, if `T` is a specialization of `iota_view` (25.6.4.2) that models `random_access_range` and `sized_range`, then `iota_view(*ranges::begin(E), *(ranges::begin(E) + std::min<D>(ranges::distance(E), F)))`, except that `E` is evaluated only once.

(2.5) — Otherwise, if `T` is a specialization of `repeat_view` (25.6.5.2):

(2.5.1) — if `T` models `sized_range`, then

```
views::repeat(*E.value_, std::min<D>(ranges::distance(E), F))
```

except that `E` is evaluated only once;

(2.5.2) — otherwise, `views::repeat(*E.value_, static_cast<D>(F))`.

(2.6) — Otherwise, `take_view(E, F)`.

3 [*Example 1*:

```
vector<int> is{0,1,2,3,4,5,6,7,8,9};
for (int i : is | views::take(5))
  cout << i << ' '; // prints 0 1 2 3 4
```

— *end example*]

25.7.10.2 Class template `take_view` [range.take.view]

```
namespace std::ranges {
  template<view V>
  class take_view : public view_interface<take_view<V>> {
  private:
    V base_ = V();                                  // exposition only
    range_difference_t<V> count_ = 0;               // exposition only

    // 25.7.10.3, class template take_view::sentinel
    template<bool> class sentinel;                  // exposition only

  public:
    take_view() requires default_initializable<V> = default;
    constexpr explicit take_view(V base, range_difference_t<V> count);
```

```
constexpr V base() const & requires copy_constructible<V> { return base_; }
constexpr V base() && { return std::move(base_); }

constexpr auto begin() requires (!simple-view<V>) {
  if constexpr (sized_range<V>) {
    if constexpr (random_access_range<V>) {
      return ranges::begin(base_);
    } else {

    if constexpr (random_access_range<const V>) {
      return ranges::begin(base_);
    } else {
      auto sz = range_difference_t<const V>(size());
      return counted_iterator(ranges::begin(base_), sz);
    }
  } else if constexpr (sized_sentinel_for<sentinel_t<const V>, iterator_t<const V>>) {
    auto it = ranges::begin(base_);
    auto sz = std::min(count_, ranges::end(base_) - it);
    return counted_iterator(std::move(it), sz);
  } else {
    return counted_iterator(ranges::begin(base_), count_);
  }
}

constexpr auto end() requires (!simple-view<V>) {
  if constexpr (sized_range<V>) {
    if constexpr (random_access_range<V>)
      return ranges::begin(base_) + range_difference_t<V>(size());
    else
      return default_sentinel;
  } else if constexpr (sized_sentinel_for<sentinel_t<V>, iterator_t<V>>) {
    return default_sentinel;
  } else {
    return sentinel<false>{ranges::end(base_)};
  }
}

constexpr auto end() const requires range<const V> {
  if constexpr (sized_range<const V>) {
    if constexpr (random_access_range<const V>)
      return ranges::begin(base_) + range_difference_t<const V>(size());
    else
      return default_sentinel;
  } else if constexpr (sized_sentinel_for<sentinel_t<const V>, iterator_t<const V>>) {
    return default_sentinel;
  } else {
    return sentinel<true>{ranges::end(base_)};
  }
}
```

```
    constexpr auto size() requires sized_range<V> {
      auto n = ranges::size(base_);
      return ranges::min(n, static_cast<decltype(n)>(count_));
    }

    constexpr auto size() const requires sized_range<const V> {
      auto n = ranges::size(base_);
      return ranges::min(n, static_cast<decltype(n)>(count_));
    }

    constexpr auto reserve_hint() {
      if constexpr (approximately_sized_range<V>) {
        auto n = static_cast<range_difference_t<V>>(ranges::reserve_hint(base_));
        return to-unsigned-like(ranges::min(n, count_));
      }
      return to-unsigned-like(count_);
    }

    constexpr auto reserve_hint() const {
      if constexpr (approximately_sized_range<const V>) {
        auto n = static_cast<range_difference_t<const V>>(ranges::reserve_hint(base_));
        return to-unsigned-like(ranges::min(n, count_));
      }
      return to-unsigned-like(count_);
    }
  };

  template<class R>
    take_view(R&&, range_difference_t<R>)
      -> take_view<views::all_t<R>>;
}

constexpr explicit take_view(V base, range_difference_t<V> count);
```

1 *Preconditions*: `count >= 0` is `true`.

2 *Effects*: Initializes *`base_`* with `std::move(base)` and *`count_`* with `count`.

25.7.10.3 Class template `take_view::`*`sentinel`* [range.take.sentinel]

```
namespace std::ranges {
  template<view V>
  template<bool Const>
  class take_view<V>::sentinel {
  private:
    using Base = maybe-const<Const, V>;                                  // exposition only
    template<bool OtherConst>
      using CI = counted_iterator<iterator_t<maybe-const<OtherConst, V>>>; // exposition only
    sentinel_t<Base> end_ = sentinel_t<Base>();                          // exposition only
    constexpr explicit sentinel(sentinel_t<Base> end);                   // exposition only

  public:
    sentinel() = default;
    constexpr sentinel(sentinel<!Const> s)
      requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;

    constexpr sentinel_t<Base> base() const;

    friend constexpr bool operator==(const CI<Const>& y, const sentinel& x);

    template<bool OtherConst = !Const>
      requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
    friend constexpr bool operator==(const CI<OtherConst>& y, const sentinel& x);
  };
}
```

```
constexpr explicit sentinel(sentinel_t<Base> end);
```

1 *Effects*: Initializes *end_* with end.

```
constexpr sentinel(sentinel<!Const> s)
  requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;
```

2 *Effects*: Initializes *end_* with std::move(s.*end_*).

```
constexpr sentinel_t<Base> base() const;
```

3 *Effects*: Equivalent to: return *end_*;

```
friend constexpr bool operator==(const CI<Const>& y, const sentinel& x);

template<bool OtherConst = !Const>
  requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
friend constexpr bool operator==(const CI<OtherConst>& y, const sentinel& x);
```

4 *Effects*: Equivalent to: return y.count() == 0 || y.base() == x.*end_*;

25.7.11 Take while view [range.take.while]

25.7.11.1 Overview [range.take.while.overview]

1 Given a unary predicate pred and a view r, take_while_view produces a view of the range [ranges::begin(r), ranges::find_if_not(r, pred)).

2 The name views::take_while denotes a range adaptor object (25.7.2). Given subexpressions E and F, the expression views::take_while(E, F) is expression-equivalent to take_while_view(E, F).

3 [*Example 1*:

```
auto input = istringstream{"0 1 2 3 4 5 6 7 8 9"};
auto small = [](const auto x) noexcept { return x < 5; };
auto small_ints = views::istream<int>(input) | views::take_while(small);
for (const auto i : small_ints) {
  cout << i << ' ';                              // prints 0 1 2 3 4
}
auto i = 0;
input >> i;
cout << i;                                       // prints 6
```

— *end example*]

25.7.11.2 Class template take_while_view [range.take.while.view]

```
namespace std::ranges {
  template<view V, class Pred>
    requires input_range<V> && is_object_v<Pred> &&
             indirect_unary_predicate<const Pred, iterator_t<V>>
  class take_while_view : public view_interface<take_while_view<V, Pred>> {
    // 25.7.11.3, class template take_while_view::sentinel
    template<bool> class sentinel;                    // exposition only

    V base_ = V();                                    // exposition only
    movable-box<Pred> pred_;                          // exposition only

  public:
    take_while_view() requires default_initializable<V> && default_initializable<Pred> = default;
    constexpr explicit take_while_view(V base, Pred pred);

    constexpr V base() const & requires copy_constructible<V> { return base_; }
    constexpr V base() && { return std::move(base_); }

    constexpr const Pred& pred() const;

    constexpr auto begin() requires (!simple-view<V>)
    { return ranges::begin(base_); }
```

```
    constexpr auto begin() const
      requires range<const V> &&
               indirect_unary_predicate<const Pred, iterator_t<const V>>
    { return ranges::begin(base_); }

    constexpr auto end() requires (!simple-view<V>)
    { return sentinel<false>(ranges::end(base_), addressof(*pred_)); }

    constexpr auto end() const
      requires range<const V> &&
               indirect_unary_predicate<const Pred, iterator_t<const V>>
    { return sentinel<true>(ranges::end(base_), addressof(*pred_)); }
  };

  template<class R, class Pred>
    take_while_view(R&&, Pred) -> take_while_view<views::all_t<R>, Pred>;
}

constexpr explicit take_while_view(V base, Pred pred);
```

1 *Effects*: Initializes *base_* with `std::move(base)` and *pred_* with `std::move(pred)`.

```
constexpr const Pred& pred() const;
```

2 *Effects*: Equivalent to: `return *pred_;`

25.7.11.3 Class template `take_while_view::sentinel` [range.take.while.sentinel]

```
namespace std::ranges {
  template<view V, class Pred>
    requires input_range<V> && is_object_v<Pred> &&
             indirect_unary_predicate<const Pred, iterator_t<V>>
  template<bool Const>
  class take_while_view<V, Pred>::sentinel {
    using Base = maybe-const<Const, V>;                                  // exposition only

    sentinel_t<Base> end_ = sentinel_t<Base>();                          // exposition only
    const Pred* pred_ = nullptr;                                         // exposition only
    constexpr explicit sentinel(sentinel_t<Base> end, const Pred* pred); // exposition only

  public:
    sentinel() = default;
    constexpr sentinel(sentinel<!Const> s)
      requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;

    constexpr sentinel_t<Base> base() const { return end_; }

    friend constexpr bool operator==(const iterator_t<Base>& x, const sentinel& y);

    template<bool OtherConst = !Const>
      requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
    friend constexpr bool operator==(const iterator_t<maybe-const<OtherConst, V>>& x,
                                     const sentinel& y);
  };
}

constexpr explicit sentinel(sentinel_t<Base> end, const Pred* pred);
```

1 *Effects*: Initializes *end_* with `end` and *pred_* with `pred`.

```
constexpr sentinel(sentinel<!Const> s)
  requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;
```

2 *Effects*: Initializes *end_* with `std::move(s.end_)` and *pred_* with `s.pred_`.

```
friend constexpr bool operator==(const iterator_t<Base>& x, const sentinel& y);
```

```
template<bool OtherConst = !Const>
  requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
friend constexpr bool operator==(const iterator_t<maybe-const<OtherConst, V>>& x,
                                 const sentinel& y);
```

3 *Effects*: Equivalent to: `return y.end_ == x || !invoke(*y.pred_, *x);`

25.7.12 Drop view [range.drop]

25.7.12.1 Overview [range.drop.overview]

1 `drop_view` produces a view excluding the first N elements from another view, or an empty range if the adapted view contains fewer than N elements.

2 The name `views::drop` denotes a range adaptor object (25.7.2). Let `E` and `F` be expressions, let `T` be `remove_cvref_t<decltype((E))>`, and let `D` be `range_difference_t<decltype((E))>`. If `decltype((F))` does not model `convertible_to<D>`, `views::drop(E, F)` is ill-formed. Otherwise, the expression `views::drop(E, F)` is expression-equivalent to:

(2.1) — If `T` is a specialization of `empty_view` (25.6.2.2), then `((void)F, decay-copy(E))`, except that the evaluations of `E` and `F` are indeterminately sequenced.

(2.2) — Otherwise, if `T` is a specialization of `optional` and `T` models `view`, then `(static_cast<D>(F) == D() ? decay-copy(E) : ((void)E, T()))`.

(2.3) — Otherwise, if `T` models `random_access_range` and `sized_range` and is

(2.3.1) — a specialization of `span` (23.7.2.2),

(2.3.2) — a specialization of `basic_string_view` (27.3),

(2.3.3) — a specialization of `iota_view` (25.6.4.2), or

(2.3.4) — a specialization of `subrange` (25.5.4) where `T::StoreSize` is `false`,

then `U(ranges::begin(E) + std::min<D>(ranges::distance(E), F), ranges::end(E))`, except that `E` is evaluated only once, where `U` is `span<typename T::element_type>` if `T` is a specialization of `span` and `T` otherwise.

(2.4) — Otherwise, if `T` is a specialization of `subrange` that models `random_access_range` and `sized_range`, then `T(ranges::begin(E) + std::min<D>(ranges::distance(E), F), ranges::end(E), to-unsigned-like(ranges::distance(E) - std::min<D>(ranges::distance(E), F)))`, except that `E` and `F` are each evaluated only once.

(2.5) — Otherwise, if `T` is a specialization of `repeat_view` (25.6.5.2):

(2.5.1) — if `T` models `sized_range`, then

```
views::repeat(*E.value_, ranges::distance(E) - std::min<D>(ranges::distance(E), F))
```

except that `E` is evaluated only once;

(2.5.2) — otherwise, `((void)F, decay-copy(E))`, except that the evaluations of `E` and `F` are indeterminately sequenced.

(2.6) — Otherwise, `drop_view(E, F)`.

3 [*Example 1*:

```
auto ints = views::iota(0) | views::take(10);
for (auto i : ints | views::drop(5)) {
  cout << i << ' ';                          // prints 5 6 7 8 9
}
```

— *end example*]

25.7.12.2 Class template `drop_view` [range.drop.view]

```
namespace std::ranges {
  template<view V>
  class drop_view : public view_interface<drop_view<V>> {
  public:
    drop_view() requires default_initializable<V> = default;
    constexpr explicit drop_view(V base, range_difference_t<V> count);
```

```
    constexpr V base() const & requires copy_constructible<V> { return base_; }
    constexpr V base() && { return std::move(base_); }

    constexpr auto begin()
      requires (!(simple-view<V> &&
                  random_access_range<const V> && sized_range<const V>));
    constexpr auto begin() const
      requires random_access_range<const V> && sized_range<const V>;

    constexpr auto end() requires (!simple-view<V>)
    { return ranges::end(base_); }

    constexpr auto end() const requires range<const V>
    { return ranges::end(base_); }

    constexpr auto size() requires sized_range<V> {
      const auto s = ranges::size(base_);
      const auto c = static_cast<decltype(s)>(count_);
      return s < c ? 0 : s - c;
    }

    constexpr auto size() const requires sized_range<const V> {
      const auto s = ranges::size(base_);
      const auto c = static_cast<decltype(s)>(count_);
      return s < c ? 0 : s - c;
    }

    constexpr auto reserve_hint() requires approximately_sized_range<V> {
      const auto s = static_cast<range_difference_t<V>>(ranges::reserve_hint(base_));
      return to-unsigned-like(s < count_ ? 0 : s - count_);
    }

    constexpr auto reserve_hint() const requires approximately_sized_range<const V> {
      const auto s = static_cast<range_difference_t<const V>>(ranges::reserve_hint(base_));
      return to-unsigned-like(s < count_ ? 0 : s - count_);
    }

  private:
    V base_ = V();                                  // exposition only
    range_difference_t<V> count_ = 0;               // exposition only
  };

  template<class R>
    drop_view(R&&, range_difference_t<R>) -> drop_view<views::all_t<R>>;
}
```

```
constexpr explicit drop_view(V base, range_difference_t<V> count);
```

1 *Preconditions*: `count >= 0` is `true`.

2 *Effects*: Initializes *base_* with `std::move(base)` and *count_* with `count`.

```
constexpr auto begin()
  requires (!(simple-view<V> &&
              random_access_range<const V> && sized_range<const V>));
constexpr auto begin() const
  requires random_access_range<const V> && sized_range<const V>;
```

3 *Returns*: `ranges::next(ranges::begin(base_), count_, ranges::end(base_))`.

4 *Remarks*: In order to provide the amortized constant-time complexity required by the `range` concept when `drop_view` models `forward_range`, the first overload caches the result within the `drop_view` for use on subsequent calls.

[*Note 1*: Without this, applying a `reverse_view` over a `drop_view` would have quadratic iteration complexity. — *end note*]

25.7.13 Drop while view [range.drop.while]

25.7.13.1 Overview [range.drop.while.overview]

1 Given a unary predicate `pred` and a view `r`, `drop_while_view` produces a view of the range [`ranges::find_if_not(r, pred)`,`ranges::end(r)`).

2 The name `views::drop_while` denotes a range adaptor object (25.7.2). Given subexpressions `E` and `F`, the expression `views::drop_while(E, F)` is expression-equivalent to `drop_while_view(E, F)`.

3 [*Example 1*:

```
constexpr auto source = "  \t   \t   \t   hello there"sv;
auto is_invisible = [](const auto x) { return x == ' ' || x == '\t'; };
auto skip_ws = views::drop_while(source, is_invisible);
for (auto c : skip_ws) {
  cout << c;                                    // prints hello there with no leading space
}
```

— *end example*]

25.7.13.2 Class template `drop_while_view` [range.drop.while.view]

```
namespace std::ranges {
  template<view V, class Pred>
    requires input_range<V> && is_object_v<Pred> &&
             indirect_unary_predicate<const Pred, iterator_t<V>>
  class drop_while_view : public view_interface<drop_while_view<V, Pred>> {
  public:
    drop_while_view() requires default_initializable<V> && default_initializable<Pred> = default;
    constexpr explicit drop_while_view(V base, Pred pred);

    constexpr V base() const & requires copy_constructible<V> { return base_; }
    constexpr V base() && { return std::move(base_); }

    constexpr const Pred& pred() const;

    constexpr auto begin();

    constexpr auto end() { return ranges::end(base_); }

  private:
    V base_ = V();                                  // exposition only
    movable-box<Pred> pred_;                        // exposition only
  };

  template<class R, class Pred>
    drop_while_view(R&&, Pred) -> drop_while_view<views::all_t<R>, Pred>;
}
```

`constexpr explicit drop_while_view(V base, Pred pred);`

1 *Effects*: Initializes *`base_`* with `std::move(base)` and *`pred_`* with `std::move(pred)`.

`constexpr const Pred& pred() const;`

2 *Effects*: Equivalent to: `return *pred_;`

`constexpr auto begin();`

3 *Preconditions*: *`pred_`*`.has_value()` is `true`.

4 *Returns*: `ranges::find_if_not(`*`base_`*`, cref(*`*`pred_`*`))`.

5 *Remarks*: In order to provide the amortized constant-time complexity required by the `range` concept when `drop_while_view` models `forward_range`, the first call caches the result within the `drop_while_view` for use on subsequent calls.

[*Note 1*: Without this, applying a `reverse_view` over a `drop_while_view` would have quadratic iteration complexity. — *end note*]

25.7.14 Join view [range.join]

25.7.14.1 Overview [range.join.overview]

1 `join_view` flattens a view of ranges into a view.

2 The name `views::join` denotes a range adaptor object (25.7.2). Given a subexpression `E`, the expression `views::join(E)` is expression-equivalent to `join_view<views::all_t<decltype((E))>>{E}`.

3 [*Example 1*:

```
vector<string> ss{"hello", " ", "world", "!"};
for (char ch : ss | views::join)
  cout << ch;                                   // prints hello world!
```

— *end example*]

25.7.14.2 Class template `join_view` [range.join.view]

```
namespace std::ranges {
  template<input_range V>
    requires view<V> && input_range<range_reference_t<V>>
  class join_view : public view_interface<join_view<V>> {
  private:
    using InnerRng = range_reference_t<V>;                  // exposition only

    // 25.7.14.3, class template join_view::iterator
    template<bool Const>
      struct iterator;                                      // exposition only

    // 25.7.14.4, class template join_view::sentinel
    template<bool Const>
      struct sentinel;                                      // exposition only

    V base_ = V();                                          // exposition only

    non-propagating-cache<iterator_t<V>> outer_;            // exposition only, present only
                                                            // when !forward_range<V>
    non-propagating-cache<remove_cv_t<InnerRng>> inner_;    // exposition only, present only
                                                            // if is_reference_v<InnerRng> is false

  public:
    join_view() requires default_initializable<V> = default;

    using value_type        = range_value_t<range_reference_t<Base>>;
```

```
    using difference_type   = see below;

    iterator() = default;
    constexpr iterator(iterator<!Const> i)
      requires Const &&
               convertible_to<iterator_t<V>, OuterIter> &&
               convertible_to<iterator_t<InnerRng>, InnerIter>;

    constexpr decltype(auto) operator*() const { return **inner_; }

    constexpr InnerIter operator->() const
      requires has-arrow<InnerIter> && copyable<InnerIter>;

    constexpr iterator& operator++();
    constexpr void operator++(int);
    constexpr iterator operator++(int)
      requires ref-is-glvalue && forward_range<Base> &&
               forward_range<range_reference_t<Base>>;

    constexpr iterator& operator--()
      requires ref-is-glvalue && bidirectional_range<Base> &&
               bidirectional_range<range_reference_t<Base>> &&
               common_range<range_reference_t<Base>>;

    constexpr iterator operator--(int)
      requires ref-is-glvalue && bidirectional_range<Base> &&
               bidirectional_range<range_reference_t<Base>> &&
               common_range<range_reference_t<Base>>;

    friend constexpr bool operator==(const iterator& x, const iterator& y)
      requires ref-is-glvalue && forward_range<Base> &&
               equality_comparable<iterator_t<range_reference_t<Base>>>;

    friend constexpr decltype(auto) iter_move(const iterator& i)
    noexcept(noexcept(ranges::iter_move(*i.inner_))) {
      return ranges::iter_move(*i.inner_);
    }

    friend constexpr void iter_swap(const iterator& x, const iterator& y)
      noexcept(noexcept(ranges::iter_swap(*x.inner_, *y.inner_)))
      requires indirectly_swappable<InnerIter>;
  };
}
```

1 *iterator*::iterator_concept is defined as follows:

(1.1) — If *ref-is-glvalue* is true, *Base* models bidirectional_range, and range_reference_t<*Base*> models both bidirectional_range and common_range, then iterator_concept denotes bidirectional_iterator_tag.

(1.2) — Otherwise, if *ref-is-glvalue* is true and *Base* and range_reference_t<*Base*> each model forward_range, then iterator_concept denotes forward_iterator_tag.

(1.3) — Otherwise, iterator_concept denotes input_iterator_tag.

2 The member *typedef-name* iterator_category is declared if and only if *ref-is-glvalue* is true, *Base* models forward_range, and range_reference_t<*Base*> models forward_range. In that case, *iterator*::iterator_category is defined as follows:

(2.1) — Let *OUTERC* denote iterator_traits<iterator_t<*Base*>>::iterator_category, and let *INNERC* denote iterator_traits<iterator_t<range_reference_t<*Base*>>>::iterator_category.

(2.2) — If *OUTERC* and *INNERC* each model derived_from<bidirectional_iterator_tag> and range_reference_t<*Base*> models common_range, iterator_category denotes bidirectional_iterator_tag.

(2.3) — Otherwise, if *OUTERC* and *INNERC* each model `derived_from<forward_iterator_tag>`, `iterator_category` denotes `forward_iterator_tag`.

(2.4) — Otherwise, `iterator_category` denotes `input_iterator_tag`.

3 *`iterator`*`::difference_type` denotes the type:

```
common_type_t<
  range_difference_t<Base>,
  range_difference_t<range_reference_t<Base>>>
```

4 `join_view` iterators use the *`satisfy`* function to skip over empty inner ranges.

```
constexpr OuterIter& outer();
constexpr const OuterIter& outer() const;
```

5 *Returns*: *`outer_`* if *`Base`* models `forward_range`; otherwise, `*`*`parent_`*`->`*`outer_`*.

```
constexpr void satisfy();
```

6 *Effects*: Equivalent to:

```
auto update_inner = [this](const iterator_t<Base>& x) -> auto&& {
  if constexpr (ref-is-glvalue)     // *x is a reference
    return *x;
  else
    return parent_->inner_.emplace-deref(x);
};

for (; outer() != ranges::end(parent_->base_); ++outer()) {
  auto&& inner = update_inner(outer());
  inner_ = ranges::begin(inner);
  if (*inner_ != ranges::end(inner))
    return;
}
if constexpr (ref-is-glvalue)
  inner_.reset();
```

```
constexpr iterator(Parent& parent, OuterIter outer)
  requires forward_range<Base>;
```

7 *Effects*: Initializes *`outer_`* with `std::move(outer)` and *`parent_`* with `addressof(parent)`; then calls *`satisfy`*`()`.

```
constexpr explicit iterator(Parent& parent)
  requires (!forward_range<Base>);
```

8 *Effects*: Initializes *`parent_`* with `addressof(parent)`; then calls *`satisfy`*`()`.

```
constexpr iterator(iterator<!Const> i)
  requires Const &&
           convertible_to<iterator_t<V>, OuterIter> &&
           convertible_to<iterator_t<InnerRng>, InnerIter>;
```

9 *Effects*: Initializes *`outer_`* with `std::move(i.`*`outer_`*`)`, *`inner_`* with `std::move(i.`*`inner_`*`)`, and *`parent_`* with `i.`*`parent_`*.

10 [*Note 1*: `Const` can only be `true` when *`Base`* models `forward_range`. — *end note*]

```
constexpr InnerIter operator->() const
  requires has-arrow<InnerIter> && copyable<InnerIter>;
```

11 *Effects*: Equivalent to: `return *`*`inner_`*`;`

```
constexpr iterator& operator++();
```

12 Let *`inner-range`* be:

(12.1) — If *`ref-is-glvalue`* is `true`, `*`*`outer`*`()`.

(12.2) — Otherwise, `*`*`parent_`*`->`*`inner_`*.

13 *Effects*: Equivalent to:

```
if (++*inner_ == ranges::end(as-lvalue(inner-range))) {
  ++outer();
  satisfy();
}
return *this;
```

```
constexpr void operator++(int);
```

14 *Effects*: Equivalent to: `++*this`.

```
constexpr iterator operator++(int)
  requires ref-is-glvalue && forward_range<Base> &&
           forward_range<range_reference_t<Base>>;
```

15 *Effects*: Equivalent to:

```
auto tmp = *this;
++*this;
return tmp;
```

```
constexpr iterator& operator--()
  requires ref-is-glvalue && bidirectional_range<Base> &&
           bidirectional_range<range_reference_t<Base>> &&
           common_range<range_reference_t<Base>>;
```

16 *Effects*: Equivalent to:

```
if (outer_ == ranges::end(parent_->base_))
  inner_ = ranges::end(as-lvalue(*--outer_));
while (*inner_ == ranges::begin(as-lvalue(*outer_)))
  *inner_ = ranges::end(as-lvalue(*--outer_));
--*inner_;
return *this;
```

```
constexpr iterator operator--(int)
  requires ref-is-glvalue && bidirectional_range<Base> &&
           bidirectional_range<range_reference_t<Base>> &&
           common_range<range_reference_t<Base>>;
```

17 *Effects*: Equivalent to:

```
auto tmp = *this;
--*this;
return tmp;
```

```
friend constexpr bool operator==(const iterator& x, const iterator& y)
  requires ref-is-glvalue && forward_range<Base> &&
           equality_comparable<iterator_t<range_reference_t<Base>>>;
```

18 *Effects*: Equivalent to: `return x.outer_ == y.outer_ && x.inner_ == y.inner_;`

```
friend constexpr void iter_swap(const iterator& x, const iterator& y)
  noexcept(noexcept(ranges::iter_swap(*x.inner_, *y.inner_)))
  requires indirectly_swappable<InnerIter>;
```

19 *Effects*: Equivalent to: `ranges::iter_swap(*x.inner_, *y.inner_);`

25.7.14.4 Class template `join_view::sentinel` [range.join.sentinel]

```
namespace std::ranges {
  template<input_range V>
    requires view<V> && input_range<range_reference_t<V>>
  template<bool Const>
  struct join_view<V>::sentinel {
  private:
    using Parent = maybe-const<Const, join_view>;       // exposition only
    using Base = maybe-const<Const, V>;                 // exposition only
    sentinel_t<Base> end_ = sentinel_t<Base>();         // exposition only
    constexpr explicit sentinel(Parent& parent);        // exposition only
```

```
  public:
    sentinel() = default;

    constexpr sentinel(sentinel<!Const> s)
      requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;

    template<bool OtherConst>
      requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
    friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);
  };
}

constexpr explicit sentinel(Parent& parent);
```

1 *Effects*: Initializes *end_* with `ranges::end(parent.base_)`.

```
constexpr sentinel(sentinel<!Const> s)
  requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;
```

2 *Effects*: Initializes *end_* with `std::move(s.end_)`.

```
template<bool OtherConst>
  requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);
```

3 *Effects*: Equivalent to: `return x.outer() == y.end_;`

25.7.15 Join with view [range.join.with]

25.7.15.1 Overview [range.join.with.overview]

1 `join_with_view` takes a view and a delimiter, and flattens the view, inserting every element of the delimiter in between elements of the view. The delimiter can be a single element or a view of elements.

2 The name `views::join_with` denotes a range adaptor object (25.7.2). Given subexpressions `E` and `F`, the expression `views::join_with(E, F)` is expression-equivalent to `join_with_view(E, F)`.

3 [*Example 1*:

```
vector<string> vs = {"the", "quick", "brown", "fox"};
for (char c : vs | views::join_with('-')) {
  cout << c;
}
// The above prints the-quick-brown-fox
```

— *end example*]

25.7.15.2 Class template `join_with_view` [range.join.with.view]

```

      visit(ranges::iter_swap, x.inner_it_, y.inner_it_);
    }
  };
}
```

1 *iterator*::iterator_concept is defined as follows:

(1.1) — If *ref-is-glvalue* is true, *Base* models bidirectional_range, and *InnerBase* and *PatternBase* each model *bidirectional-common*, then iterator_concept denotes bidirectional_iterator_tag.

(1.2) — Otherwise, if *ref-is-glvalue* is true and *Base* and *InnerBase* each model forward_range, then iterator_concept denotes forward_iterator_tag.

(1.3) — Otherwise, iterator_concept denotes input_iterator_tag.

2 The member *typedef-name* iterator_category is declared if and only if *ref-is-glvalue* is true, and *Base* and *InnerBase* each model forward_range. In that case, *iterator*::iterator_category is defined as follows:

(2.1) — Let *OUTERC* denote iterator_traits<*OuterIter*>::iterator_category, let *INNERC* denote iterator_traits<*InnerIter*>::iterator_category, and let *PATTERNC* denote iterator_traits<*PatternIter*>::iterator_category.

(2.2) — If

```
is_reference_v<common_reference_t<iter_reference_t<InnerIter>,
                                  iter_reference_t<PatternIter>>>
```

is false, iterator_category denotes input_iterator_tag.

(2.3) — Otherwise, if *OUTERC*, *INNERC*, and *PATTERNC* each model derived_from<bidirectional_iterator_tag> and *InnerBase* and *PatternBase* each model common_range, iterator_category denotes bidirectional_iterator_tag.

(2.4) — Otherwise, if *OUTERC*, *INNERC*, and *PATTERNC* each model derived_from<forward_iterator_tag>, iterator_category denotes forward_iterator_tag.

(2.5) — Otherwise, iterator_category denotes input_iterator_tag.

3 *iterator*::value_type denotes the type:

```
common_type_t<iter_value_t<InnerIter>, iter_value_t<PatternIter>>
```

4 *iterator*::difference_type denotes the type:

```
  common_type_t<
    iter_difference_t<OuterIter>,
    iter_difference_t<InnerIter>,
    iter_difference_t<PatternIter>>

constexpr OuterIter& outer();
constexpr const OuterIter& outer() const;
```

5 *Returns*: `outer_it_` if `Base` models `forward_range`; otherwise, `*parent_->outer_it_`.

```
constexpr auto& update-inner();
```

6 *Effects*: Equivalent to:

```
  if constexpr (ref-is-glvalue)
    return as-lvalue(*outer());
  else
    return parent_->inner_.emplace-deref(outer());
```

```
constexpr auto& get-inner();
```

7 *Effects*: Equivalent to:

```
  if constexpr (ref-is-glvalue)
    return as-lvalue(*outer());
  else
    return *parent_->inner_;
```

```
constexpr void satisfy();
```

8 *Effects*: Equivalent to:

```
  while (true) {
    if (inner_it_.index() == 0) {
      if (std::get<0>(inner_it_) != ranges::end(parent_->pattern_))
        break;
      inner_it_.template emplace<1>(ranges::begin(update-inner()));
    } else {
      if (std::get<1>(inner_it_) != ranges::end(get-inner()))
        break;
      if (++outer() == ranges::end(parent_->base_)) {
        if constexpr (ref-is-glvalue)
          inner_it_.template emplace<0>();
        break;
      }
      inner_it_.template emplace<0>(ranges::begin(parent_->pattern_));
    }
  }
```

[*Note 1*: `join_with_view` iterators use the *satisfy* function to skip over empty inner ranges. — *end note*]

```
constexpr iterator(Parent& parent, OuterIter outer)
  requires forward_range<Base>;
constexpr explicit iterator(Parent& parent)
  requires (!forward_range<Base>);
```

9 *Effects*: Initializes *parent_* with `addressof(parent)`. For the first overload, also initializes *outer_it_* with `std::move(outer)`. Then, equivalent to:

```
  if (outer() != ranges::end(parent_->base_)) {
    inner_it_.template emplace<1>(ranges::begin(update-inner()));
    satisfy();
  }
```

```
constexpr iterator(iterator<!Const> i)
    requires Const && convertible_to<iterator_t<V>, OuterIter> &&
             convertible_to<iterator_t<InnerRng>, InnerIter> &&
             convertible_to<iterator_t<Pattern>, PatternIter>;
```

10 *Effects*: Initializes *outer_it_* with `std::move(i.outer_it_)` and *parent_* with `i.parent_`. Then, equivalent to:

```
if (i.inner_it_.index() == 0)
  inner_it_.template emplace<0>(std::get<0>(std::move(i.inner_it_)));
else
  inner_it_.template emplace<1>(std::get<1>(std::move(i.inner_it_)));
```

11 [*Note 2*: `Const` can only be `true` when *`Base`* models `forward_range`. — *end note*]

```
constexpr decltype(auto) operator*() const;
```

12 *Effects*: Equivalent to:

```
using reference =
  common_reference_t<iter_reference_t<InnerIter>, iter_reference_t<PatternIter>>;
return visit([](auto& it) -> reference { return *it; }, inner_it_);
```

```
constexpr iterator& operator++();
```

13 *Effects*: Equivalent to:

```
visit([](auto& it){ ++it; }, inner_it_);
satisfy();
return *this;
```

```
constexpr void operator++(int);
```

14 *Effects*: Equivalent to `++*this`.

```
constexpr iterator operator++(int)
  requires ref-is-glvalue && forward_iterator<OuterIter> && forward_iterator<InnerIter>;
```

15 *Effects*: Equivalent to:

```
iterator tmp = *this;
++*this;
return tmp;
```

```
constexpr iterator& operator--()
  requires ref-is-glvalue && bidirectional_range<Base> &&
           bidirectional-common<InnerBase> && bidirectional-common<PatternBase>;
```

16 *Effects*: Equivalent to:

```
if (outer_it_ == ranges::end(parent_->base_)) {
  auto&& inner = *--outer_it_;
  inner_it_.template emplace<1>(ranges::end(inner));
}

while (true) {
  if (inner_it_.index() == 0) {
    auto& it = std::get<0>(inner_it_);
    if (it == ranges::begin(parent_->pattern_)) {
      auto&& inner = *--outer_it_;
      inner_it_.template emplace<1>(ranges::end(inner));
    } else {
      break;
    }
  } else {
    auto& it = std::get<1>(inner_it_);
    auto&& inner = *outer_it_;
    if (it == ranges::begin(inner)) {
      inner_it_.template emplace<0>(ranges::end(parent_->pattern_));
    } else {
      break;
    }
  }
}
visit([](auto& it){ --it; }, inner_it_);
return *this;
```

```
constexpr iterator operator--(int)
  requires ref-is-glvalue && bidirectional_range<Base> &&
           bidirectional-common<InnerBase> && bidirectional-common<PatternBase>;
```

17 *Effects*: Equivalent to:

```
iterator tmp = *this;
--*this;
return tmp;
```

```
friend constexpr bool operator==(const iterator& x, const iterator& y)
  requires ref-is-glvalue && forward_range<Base> &&
           equality_comparable<InnerIter>;
```

18 *Effects*: Equivalent to:

```
return x.outer_it_ == y.outer_it_ && x.inner_it_ == y.inner_it_;
```

25.7.15.4 Class template `join_with_view::sentinel` [range.join.with.sentinel]

```
namespace std::ranges {
  template<input_range V, forward_range Pattern>
    requires view<V> && input_range<range_reference_t<V>>
          && view<Pattern> && concatable<range_reference_t<V>, Pattern>

      requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
    friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);
  };
}
```

```
constexpr explicit sentinel(Parent& parent);
```

1 *Effects*: Initializes *end_* with `ranges::end(parent.base_)`.

```
constexpr sentinel(sentinel<!Const> s)
  requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;
```

2 *Effects*: Initializes *end_* with `std::move(s.end_)`.

```
template<bool OtherConst>
  requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);
```

3 *Effects*: Equivalent to: `return x.outer() == y.end_;`

25.7.16 Lazy split view [range.lazy.split]

25.7.16.1 Overview [range.lazy.split.overview]

1 `lazy_split_view` takes a view and a delimiter, and splits the view into subranges on the delimiter. The delimiter can be a single element or a view of elements.

2 The name `views::lazy_split` denotes a range adaptor object (25.7.2). Given subexpressions `E` and `F`, the expression `views::lazy_split(E, F)` is expression-equivalent to `lazy_split_view(E, F)`.

3 [*Example 1*:

```
string str{"the quick brown fox"};
```

```
for (auto word : str | views::lazy_split(' ')) {
  for (char ch : word)
    cout << ch;
  cout << '*';
}
// The above prints the*quick*brown*fox*
```

— *end example*]

25.7.16.2 Class template `lazy_split_view` [range.lazy.split.view]

```
namespace std::ranges {

                                                             // if V models forward_range

    bool trailing_empty_ = false;                            // exposition only
    constexpr explicit outer-iterator(Parent& parent)        // exposition only
      requires (!forward_range<Base>);
    constexpr outer-iterator(Parent& parent, iterator_t<Base> current)     // exposition only
      requires forward_range<Base>;

  public:
    using iterator_concept  =
      conditional_t<forward_range<Base>, forward_iterator_tag, input_iterator_tag>;

    using iterator_category = input_iterator_tag;            // present only if Base
                                                             // models forward_range

    // 25.7.16.4, class lazy_split_view::outer-iterator::value_type
    struct value_type;
```

```
    using difference_type   = range_difference_t<Base>;

    outer-iterator() = default;
    constexpr outer-iterator(outer-iterator<!Const> i)
      requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;

    constexpr value_type operator*() const;

    constexpr outer-iterator& operator++();
    constexpr decltype(auto) operator++(int) {
      if constexpr (forward_range<Base>) {
        auto tmp = *this;
        ++*this;
        return tmp;
      } else
        ++*this;
    }

    friend constexpr bool operator==(const outer-iterator& x, const outer-iterator& y)
      requires forward_range<Base>;

    friend constexpr bool operator==(const outer-iterator& x, default_sentinel_t);
  };
}
```

1 Many of the specifications in 25.7.16 refer to the notional member *current* of *outer-iterator*. *current* is equivalent to *current_* if V models forward_range, and **parent_->current_* otherwise.

```
constexpr explicit outer-iterator(Parent& parent)
  requires (!forward_range<Base>);
```

2 *Effects*: Initializes *parent_* with addressof(parent).

```
constexpr outer-iterator(Parent& parent, iterator_t<Base> current)
  requires forward_range<Base>;
```

3 *Effects*: Initializes *parent_* with addressof(parent) and *current_* with std::move(current).

```
constexpr outer-iterator(outer-iterator<!Const> i)
  requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;
```

4 *Effects*: Initializes *parent_* with i.*parent_*, *current_* with std::move(i.*current_*), and *trailing_empty_* with i.*trailing_empty_*.

```
constexpr value_type operator*() const;
```

5 *Effects*: Equivalent to: return value_type{*this};

```
constexpr outer-iterator& operator++();
```

6 *Effects*: Equivalent to:

```
const auto end = ranges::end(parent_->base_);
if (current == end) {
  trailing_empty_ = false;
  return *this;
}
const auto [pbegin, pend] = subrange{parent_->pattern_};
if (pbegin == pend) ++current;
else if constexpr (tiny-range<Pattern>) {
  current = ranges::find(std::move(current), end, *pbegin);
  if (current != end) {
    ++current;
    if (current == end)
      trailing_empty_ = true;
  }
}
```

©ISO/IEC

```
      else {
        do {
          auto [b, p] = ranges::mismatch(current, end, pbegin, pend);
          if (p == pend) {
            current = b;
            if (current == end)
              trailing_empty_ = true;
            break;            // The pattern matched; skip it
          }
        } while (++current != end);
      }
      return *this;
```

```
friend constexpr bool operator==(const outer-iterator& x, const outer-iterator& y)
  requires forward_range<Base>;
```

7 *Effects*: Equivalent to:

```
return x.current_ == y.current_ && x.trailing_empty_ == y.trailing_empty_;
```

```
friend constexpr bool operator==(const outer-iterator& x, default_sentinel_t);
```

8 *Effects*: Equivalent to:

```
return x.current == ranges::end(x.parent_->base_) && !x.trailing_empty_;
```

25.7.16.4 Class `lazy_split_view::outer-iterator::value_type` [range.lazy.split.outer.value]

```
namespace std::ranges {
  template<input_range V, forward_range Pattern>
    requires view<V> && view<Pattern> &&
             indirectly_comparable<iterator_t<V>, iterator_t<Pattern>, ranges::equal_to> &&
             (forward_range<V> || tiny-range<Pattern>)

    constexpr default_sentinel_t end() const noexcept;
  };
}
```

```
constexpr explicit value_type(outer-iterator i);
```

1 *Effects*: Initializes $i\_$ with `std::move(i)`.

```
constexpr inner-iterator<Const> begin() const;
```

2 *Effects*: Equivalent to: `return inner-iterator<Const>{i_};`

```
constexpr default_sentinel_t end() const noexcept;
```

3 *Effects*: Equivalent to: `return default_sentinel;`

25.7.16.5 Class template `lazy_split_view::inner-iterator` [range.lazy.split.inner]

```
namespace std::ranges {
  template<input_range V, forward_range Pattern>
    requires view<V> && view<Pattern> &&
             indirectly_comparable<iterator_t<V>, iterator_t<Pattern>, ranges::equal_to> &&
             (forward_range<V> || tiny-range<Pattern>)
  template<bool Const>
  struct lazy_split_view<V, Pattern>::inner-iterator {
  private:
    using Base = maybe-const<Const, V>;                    // exposition only
```

```
    outer-iterator<Const> i_ = outer-iterator<Const>();              // exposition only
    bool incremented_ = false;                                       // exposition only
    constexpr explicit inner-iterator(outer-iterator<Const> i);      // exposition only

  public:
    using iterator_concept  = outer-iterator<Const>::iterator_concept;

    using iterator_category = see below;                             // present only if Base
                                                                     // models forward_range
    using value_type        = range_value_t<Base>;
    using difference_type   = range_difference_t<Base>;

    inner-iterator() = default;

    constexpr const iterator_t<Base>& base() const & noexcept;
    constexpr iterator_t<Base> base() && requires forward_range<V>;

    constexpr decltype(auto) operator*() const { return *i_.current; }

    constexpr inner-iterator& operator++();
    constexpr decltype(auto) operator++(int) {
      if constexpr (forward_range<Base>) {
        auto tmp = *this;
        ++*this;
        return tmp;
      } else
        ++*this;
    }

    friend constexpr bool operator==(const inner-iterator& x, const inner-iterator& y)
      requires forward_range<Base>;

    friend constexpr bool operator==(const inner-iterator& x, default_sentinel_t);

    friend constexpr decltype(auto) iter_move(const inner-iterator& i)
    noexcept(noexcept(ranges::iter_move(i.i_.current))) {
      return ranges::iter_move(i.i_.current);
    }

    friend constexpr void iter_swap(const inner-iterator& x, const inner-iterator& y)
      noexcept(noexcept(ranges::iter_swap(x.i_.current, y.i_.current)))
      requires indirectly_swappable<iterator_t<Base>>;
  };
}
```

1 If *Base* does not model `forward_range` there is no member `iterator_category`. Otherwise, the *typedef-name* `iterator_category` denotes:

(1.1) — `forward_iterator_tag` if `iterator_traits<iterator_t<`*Base*`>>::iterator_category` models `derived_from<forward_iterator_tag>`;

(1.2) — otherwise, `iterator_traits<iterator_t<`*Base*`>>::iterator_category`.

```
constexpr explicit inner-iterator(outer-iterator<Const> i);
```

2 *Effects*: Initializes *i_* with `std::move(i)`.

```
constexpr const iterator_t<Base>& base() const & noexcept;
```

3 *Effects*: Equivalent to: `return i_.current;`

```
constexpr iterator_t<Base> base() && requires forward_range<V>;
```

4 *Effects*: Equivalent to: `return std::move(i_.current);`

```
constexpr inner-iterator& operator++();
```

5 *Effects*: Equivalent to:

```
      incremented_ = true;
      if constexpr (!forward_range<Base>) {
        if constexpr (Pattern::size() == 0) {
          return *this;
        }
      }
      ++i_.current;
      return *this;
```

```
friend constexpr bool operator==(const inner-iterator& x, const inner-iterator& y)
  requires forward_range<Base>;
```

6 *Effects*: Equivalent to: `return x.i_.current == y.i_.current;`

```
friend constexpr bool operator==(const inner-iterator& x, default_sentinel_t);
```

7 *Effects*: Equivalent to:

```
      auto [pcur, pend] = subrange{x.i_.parent_->pattern_};
      auto end = ranges::end(x.i_.parent_->base_);
      if constexpr (tiny-range<Pattern>) {

        if (cur == end) return true;
        if (pcur == pend) return x.incremented_;
        return *cur == *pcur;
      } else {
        auto cur = x.i_.current;
        if (cur == end) return true;
        if (pcur == pend) return x.incremented_;
        do {
          if (*cur != *pcur) return false;
          if (++pcur == pend) return true;
        } while (++cur != end);
        return false;
      }
```

```
friend constexpr void iter_swap(const inner-iterator& x, const inner-iterator& y)
  noexcept(noexcept(ranges::iter_swap(x.i_.current, y.i_.current)))
  requires indirectly_swappable<iterator_t<Base>>;
```

8 *Effects*: Equivalent to `ranges::iter_swap(x.i_.current, y.i_.current)`.

25.7.17 Split view [range.split]

25.7.17.1 Overview [range.split.overview]

1 `split_view` takes a view and a delimiter, and splits the view into `subrange`s on the delimiter. The delimiter can be a single element or a view of elements.

2 The name `views::split` denotes a range adaptor object (25.7.2). Given subexpressions `E` and `F`, the expression `views::split(E, F)` is expression-equivalent to `split_view(E, F)`.

3 [*Example 1*:

```
string str{"the quick brown fox"};
for (auto word : views::split(str, ' ')) {
  cout << string_view(word) << '*';
}
// The above prints the*quick*brown*fox*
```

— *end example*]

25.7.17.2 Class template `split_view` [range.split.view]

```
namespace std::ranges {
  template<forward_range V, forward_range Pattern>
    requires view<V> && view<Pattern> &&
             indirectly_comparable<iterator_t<V>, iterator_t<Pattern>, ranges::equal_to>
  class split_view : public view_interface<split_view<V, Pattern>> {
  private:
    V base_ = V();                                  // exposition only
```

```
    Pattern pattern_ = Pattern();                // exposition only

    // 25.7.17.3, class split_view::iterator
    struct iterator;                             // exposition only

    // 25.7.17.4, class split_view::sentinel
    struct sentinel;                             // exposition only

  public:
    split_view()
      requires default_initializable<V> && default_initializable<Pattern> = default;
    constexpr explicit split_view(V base, Pattern pattern);

    template<forward_range R>
      requires constructible_from<V, views::all_t<R>> &&
               constructible_from<Pattern, single_view<range_value_t<R>>>
    constexpr explicit split_view(R&& r, range_value_t<R> e);

    constexpr V base() const & requires copy_constructible<V> { return base_; }
    constexpr V base() && { return std::move(base_); }

    constexpr iterator begin();

    constexpr auto end() {
      if constexpr (common_range<V>) {
        return iterator{*this, ranges::end(base_), {}};
      } else {
        return sentinel{*this};
      }
    }

    constexpr subrange<iterator_t<V>> find-next(iterator_t<V>); // exposition only
  };

  template<class R, class P>
    split_view(R&&, P&&) -> split_view<views::all_t<R>, views::all_t<P>>;

  template<forward_range R>
    split_view(R&&, range_value_t<R>)
      -> split_view<views::all_t<R>, single_view<range_value_t<R>>>;
}
```

```
constexpr explicit split_view(V base, Pattern pattern);
```

1 *Effects*: Initializes *base_* with `std::move(base)`, and *pattern_* with `std::move(pattern)`.

```
template<forward_range R>
  requires constructible_from<V, views::all_t<R>> &&
           constructible_from<Pattern, single_view<range_value_t<R>>>
constexpr explicit split_view(R&& r, range_value_t<R> e);
```

2 *Effects*: Initializes *base_* with `views::all(std::forward<R>(r))`, and *pattern_* with `views::single(std::move(e))`.

```
constexpr iterator begin();
```

3 *Returns*: `{*this, ranges::begin(base_), find-next(ranges::begin(base_))}`.

4 *Remarks*: In order to provide the amortized constant time complexity required by the `range` concept, this function caches the result within the `split_view` for use on subsequent calls.

```
constexpr subrange<iterator_t<V>> find-next(iterator_t<V> it);
```

5 *Effects*: Equivalent to:

```
auto [b, e] = ranges::search(subrange(it, ranges::end(base_)), pattern_);
if (b != ranges::end(base_) && ranges::empty(pattern_)) {
  ++b;
```

```
      ++e;
    }
    return {b, e};
```

25.7.17.3 Class `split_view::iterator` [range.split.iterator]

```
namespace std::ranges {
  template<forward_range V, forward_range Pattern>
    requires view<V> && view<Pattern> &&
             indirectly_comparable<iterator_t<V>, iterator_t<Pattern>, ranges::equal_to>

    bool trailing_empty_ = false;                                           // exposition only
    constexpr iterator(split_view& parent, iterator_t<V> current,           // exposition only
                       subrange<iterator_t<V>> next);

  public:
    using iterator_concept = forward_iterator_tag;
    using iterator_category = input_iterator_tag;
    using value_type = subrange<iterator_t<V>>;
    using difference_type = range_difference_t<V>;

    iterator() = default;

    constexpr iterator_t<V> base() const;
    constexpr value_type operator*() const;

    constexpr iterator& operator++();
    constexpr iterator operator++(int);

    friend constexpr bool operator==(const iterator& x, const iterator& y);
  };
}
```

`constexpr iterator(split_view& parent, iterator_t<V> current, subrange<iterator_t<V>> next);`

1 *Effects*: Initializes *parent_* with `addressof(parent)`, *cur_* with `std::move(current)`, and *next_* with `std::move(next)`.

`constexpr iterator_t<V> base() const;`

2 *Effects*: Equivalent to: `return cur_;`

`constexpr value_type operator*() const;`

3 *Effects*: Equivalent to: `return {cur_, next_.begin()};`

`constexpr iterator& operator++();`

4 *Effects*: Equivalent to:

```
cur_ = next_.begin();
if (cur_ != ranges::end(parent_->base_)) {
  cur_ = next_.end();
  if (cur_ == ranges::end(parent_->base_)) {
    trailing_empty_ = true;
    next_ = {cur_, cur_};
  } else {
    next_ = parent_->find-next(cur_);
  }
} else {
  trailing_empty_ = false;
}
return *this;
```

```
constexpr iterator operator++(int);
```

5 *Effects*: Equivalent to:

```
auto tmp = *this;
++*this;
return tmp;
```

```
friend constexpr bool operator==(const iterator& x, const iterator& y);
```

6 *Effects*: Equivalent to:

```
return x.cur_ == y.cur_ && x.trailing_empty_ == y.trailing_empty_;
```

25.7.17.4 Class `split_view::sentinel` [range.split.sentinel]

```
namespace std::ranges {
  template<forward_range V, forward_range Pattern>
    requires view<V> && view<Pattern> &&
             indirectly_comparable<iterator_t<V>, iterator_t<Pattern>, ranges::equal_to>
  struct split_view<V, Pattern>::sentinel {
  private:
    sentinel_t<V> end_ = sentinel_t<V>();               // exposition only
    constexpr explicit sentinel(split_view& parent);    // exposition only

  public:
    sentinel() = default;

    friend constexpr bool operator==(const iterator& x, const sentinel& y);
  };
}
```

```
constexpr explicit sentinel(split_view& parent);
```

1 *Effects*: Initializes `end_` with `ranges::end(parent.base_)`.

```
friend constexpr bool operator==(const iterator& x, const sentinel& y);
```

2 *Effects*: Equivalent to: `return x.cur_ == y.end_ && !x.trailing_empty_;`

25.7.18 Concat view [range.concat]

25.7.18.1 Overview [range.concat.overview]

1 `concat_view` presents a view that concatenates all the underlying ranges.

2 The name `views::concat` denotes a customization point object (16.3.3.3.5). Given a pack of subexpressions `Es...`, the expression `views::concat(Es...)` is expression-equivalent to

(2.1) — `views::all(Es...)` if `Es` is a pack with only one element whose type models `input_range`,

(2.2) — otherwise, `concat_view(Es...)`.

[*Example 1*:

```
vector<int> v1{1, 2, 3}, v2{4, 5}, v3{};
array a{6, 7, 8};
auto s = views::single(9);
for (auto&& i : views::concat(v1, v2, v3, a, s)) {
  print("{} ", i);      // prints 1 2 3 4 5 6 7 8 9
}
```

— *end example*]

25.7.18.2 Class template `concat_view` [range.concat.view]

```
namespace std::ranges {
  template<class... Rs>
  using concat-reference-t = common_reference_t<range_reference_t<Rs>...>;       // exposition only
  template<class... Rs>
  using concat-value-t = common_type_t<range_value_t<Rs>...>;                    // exposition only
  template<class... Rs>
  using concat-rvalue-reference-t =                                              // exposition only
    common_reference_t<range_rvalue_reference_t<Rs>...>;
```

```
    template<class... Rs>
      concept concat-indirectly-readable = see below;      // exposition only
    template<class... Rs>
      concept concatable = see below;                      // exposition only
    template<bool Const, class... Rs>
      concept concat-is-random-access = see below;         // exposition only
    template<bool Const, class... Rs>
      concept concat-is-bidirectional = see below;         // exposition only

    template<input_range... Views>
      requires (view<Views> && ...) && (sizeof...(Views) > 0) &&
                concatable<Views...>
    class concat_view : public view_interface<concat_view<Views...>> {

      tuple<Views...> views_;                                          // exposition only

      // 25.7.18.3, class template concat_view::iterator
      template<bool> class iterator;                                   // exposition only

    public:
      constexpr concat_view() = default;
      constexpr explicit concat_view(Views... views);

      constexpr iterator<false> begin() requires (!(simple-view<Views> && ...));
      constexpr iterator<true> begin() const
        requires (range<const Views> && ...) && concatable<const Views...>;

      constexpr auto end() requires (!(simple-view<Views> && ...));
      constexpr auto end() const
        requires (range<const Views> && ...) && concatable<const Views...>;

      constexpr auto size() requires (sized_range<Views> && ...);
      constexpr auto size() const requires (sized_range<const Views> && ...);
      constexpr auto reserve_hint() requires (approximately_sized_range<Views> && ...);
      constexpr auto reserve_hint() const requires (approximately_sized_range<const Views> && ...);
    };

    template<class... R>
      concat_view(R&&...) -> concat_view<views::all_t<R>...>;
  }

template<class... Rs>
  concept concat-indirectly-readable = see below;                      // exposition only
```

1 The exposition-only *concat-indirectly-readable* concept is equivalent to:

```
    template<class Ref, class RRef, class It>
      concept concat-indirectly-readable-impl =                        // exposition only
        requires (const It it) {
          { *it } -> convertible_to<Ref>;
          { ranges::iter_move(it) } -> convertible_to<RRef>;
        };

    template<class... Rs>
      concept concat-indirectly-readable =                             // exposition only
        common_reference_with<concat-reference-t<Rs...>&&,
                              concat-value-t<Rs...>&> &&
        common_reference_with<concat-reference-t<Rs...>&&,
                              concat-rvalue-reference-t<Rs...>&&> &&
        common_reference_with<concat-rvalue-reference-t<Rs...>&&,
                              concat-value-t<Rs...> const&> &&
        (concat-indirectly-readable-impl<concat-reference-t<Rs...>,
                                         concat-rvalue-reference-t<Rs...>,
                                         iterator_t<Rs>> && ...);
```

```
template<class... Rs>
  concept concatable = see below;                                    // exposition only
```

2 The exposition-only *concatable* concept is equivalent to:

```
template<class... Rs>
  concept concatable = requires {                                    // exposition only
    typename concat-reference-t<Rs...>;
    typename concat-value-t<Rs...>;
    typename concat-rvalue-reference-t<Rs...>;
  } && concat-indirectly-readable<Rs...>;
```

```
template<bool Const, class... Rs>
  concept concat-is-random-access = see below;                       // exposition only
```

3 Let Fs be the pack that consists of all elements of Rs except the last element, then *concat-is-random-access* is equivalent to:

```
template<bool Const, class... Rs>
  concept concat-is-random-access =                                  // exposition only
    all-random-access<Const, Rs...> &&
    (common_range<maybe-const<Const, Fs>> && ...);
```

```
template<bool Const, class... Rs>
  concept concat-is-bidirectional = see below;                       // exposition only
```

4 Let Fs be the pack that consists of all elements of Rs except the last element, then *concat-is-bidirectional* is equivalent to:

```
template<bool Const, class... Rs>
  concept concat-is-bidirectional =                                  // exposition only
    all-bidirectional<Const, Rs...> &&
    (common_range<maybe-const<Const, Fs>> && ...);
```

```
constexpr explicit concat_view(Views... views);
```

5 *Effects*: Initializes *views_* with std::move(views)....

```
constexpr iterator<false> begin() requires (!(simple-view<Views> && ...));
constexpr iterator<true> begin() const
  requires (range<const Views> && ...) && concatable<const Views...>;
```

6 *Effects*: Let *is-const* be true for the const-qualified overload, and false otherwise. Equivalent to:

```
iterator<is-const> it(this, in_place_index<0>, ranges::begin(std::get<0>(views_)));
it.template satisfy<0>();
return it;
```

```
constexpr auto end() requires (!(simple-view<Views> && ...));
constexpr auto end() const
  requires (range<const Views> && ...) && concatable<const Views...>;
```

7 *Effects*: Let *is-const* be true for the const-qualified overload, and false otherwise. Equivalent to:

```
constexpr auto N = sizeof...(Views);
if constexpr (all-forward<is-const, Views...> &&
              common_range<maybe-const<is-const, Views...[N - 1]>>) {
  return iterator<is-const>(this, in_place_index<N - 1>,
                            ranges::end(std::get<N - 1>(views_)));
} else {
  return default_sentinel;
}
```

```
constexpr auto size() requires (sized_range<Views> && ...);
constexpr auto size() const requires (sized_range<const Views> && ...);
```

8 *Effects*: Equivalent to:

```
return apply(
  [](auto... sizes) {
    using CT = make-unsigned-like-t<common_type_t<decltype(sizes)...>>;
    return (CT(sizes) + ...);
```

```
      },
      tuple-transform(ranges::size, views_));

constexpr auto reserve_hint() requires (approximately_sized_range<Views> && ...);
constexpr auto reserve_hint() const requires (approximately_sized_range<const Views> && ...);
```

9 *Effects*: Equivalent to:

```
return apply(
  [](auto... sizes) {
    using CT = make-unsigned-like-t<common_type_t<decltype(sizes)...>>;
    return (CT(sizes) + ...);
  },
  tuple-transform(ranges::reserve_hint, views_));
```

25.7.18.3 Class `concat_view::iterator` [range.concat.iterator]

```
namespace std::ranges {

}
```

1 *iterator*::iterator_concept is defined as follows:

(1.1) — If *concat-is-random-access*<Const, Views...> is modeled, then iterator_concept denotes random_access_iterator_tag.

(1.2) — Otherwise, if *concat-is-bidirectional*<Const, Views...> is modeled, then iterator_concept denotes bidirectional_iterator_tag.

(1.3) — Otherwise, if *all-forward*<Const, Views...> is modeled, then iterator_concept denotes forward_iterator_tag.

(1.4) — Otherwise, iterator_concept denotes input_iterator_tag.

2 The member *typedef-name* iterator_category is declared if and only if *all-forward*<Const, Views...> is modeled. In that case, *iterator*::iterator_category is defined as follows:

(2.1) — If is_reference_v<*concat-reference-t*<*maybe-const*<Const, Views>...>> is false, then iterator_category denotes input_iterator_tag.

(2.2) — Otherwise, let Cs denote the pack of types iterator_traits<iterator_t<*maybe-const*<Const, Views>>>::iterator_category....

(2.2.1) — If (derived_from<Cs, random_access_iterator_tag> && ...) && *concat-is-random-access*<Const, Views...> is true, iterator_category denotes random_access_iterator_tag.

(2.2.2) — Otherwise, if `(derived_from<Cs, bidirectional_iterator_tag> && ...) && *concat-is-bidirectional*<Const, Views...>` is `true`, `iterator_category` denotes `bidirectional_iterator_tag`.

(2.2.3) — Otherwise, if `(derived_from<Cs, forward_iterator_tag> && ...)` is `true`, `iterator_category` denotes `forward_iterator_tag`.

(2.2.4) — Otherwise, `iterator_category` denotes `input_iterator_tag`.

```

```

33 *Preconditions*: `x.it_.valueless_by_exception()` and `y.it_.valueless_by_exception()` are each `false`.

34 *Effects*: Let i_x denote `x.it_.index()` and i_y denote `y.it_.index()`.

(34.1) — If i_x `>` i_y, let d_y be `ranges::distance(std::get<`i_y`>(y.it_), ranges::end(std::get<`i_y`>(y.parent_->views_)))`, d_x be `ranges::distance(ranges::begin(std::get<`i_x`>(x.parent_->views_)), std::get<`i_x`>(x.it_))`. Let s denote the sum of the sizes of all the ranges `std::get<`i`>(x.parent_->views_)` for every integer i in the range $[i_y$ `+ 1`$, i_x)$ if there is any, and `0` otherwise, of type `difference_type`, equivalent to:

```
    return d_y + s + d_x;
```

(34.2) — otherwise, if i_x `<` i_y is `true`, equivalent to:

```
    return -(y - x);
```

(34.3) — otherwise, equivalent to:

```
    return std::get<i_x>(x.it_) - std::get<i_y>(y.it_);
```

```
friend constexpr difference_type operator-(const iterator& x, default_sentinel_t)
  requires see below;
```

35 *Preconditions*: `x.it_.valueless_by_exception()` is `false`.

36 *Effects*: Let i_x denote `x.it_.index()`, d_x be `ranges::distance(std::get<`i_x`>(x.it_), ranges::end(std::get<`i_x`>(x.parent_->views_)))`. Let s denote the sum of the sizes of all the ranges `std::get<`i`>(x.parent_->views_)` for every integer i in the range $[i_x$ `+ 1,sizeof...(Views))` if there is any, and `0` otherwise, of type difference_type, equivalent to:

```
    return -(d_x + s);
```

37 *Remarks*: Let `Fs` be the pack that consists of all elements of `Views` except the first element, the expression in the *requires-clause* is equivalent to:

```
    (sized_sentinel_for<sentinel_t<maybe-const<Const, Views>>,
                        iterator_t<maybe-const<Const, Views>>> && ...) &&
    (sized_range<maybe-const<Const, Fs>> && ...)
```

```
friend constexpr difference_type operator-(default_sentinel_t, const iterator& x)
  requires see below;
```

38 *Effects*: Equivalent to:

```
    return -(x - default_sentinel);
```

39 *Remarks*: Let `Fs` be the pack that consists of all elements of `Views` except the first element, the expression in the *requires-clause* is equivalent to:

```
    (sized_sentinel_for<sentinel_t<maybe-const<Const, Views>>,
                        iterator_t<maybe-const<Const, Views>>> && ...) &&
    (sized_range<maybe-const<Const, Fs>> && ...)
```

```
friend constexpr decltype(auto) iter_move(const iterator& it) noexcept(see below);
```

40 *Preconditions*: `it.it_.valueless_by_exception()` is `false`.

41 *Effects*: Equivalent to:

```
return std::visit([](const auto& i)
                  -> concat-rvalue-reference-t<maybe-const<Const, Views>...> {
                    return ranges::iter_move(i);
                  },
                  it.it_);
```

42 *Remarks*: The exception specification is equivalent to:

```
((is_nothrow_invocable_v<decltype(ranges::iter_move),
                         const iterator_t<maybe-const<Const, Views>>&> &&
  is_nothrow_convertible_v<range_rvalue_reference_t<maybe-const<Const, Views>>,
                           concat-rvalue-reference-t<maybe-const<Const, Views>...>>) &&
 ...)
```

```
friend constexpr void iter_swap(const iterator& x, const iterator& y) noexcept(see below)
  requires see below;
```

43 *Preconditions*: `x.it_.valueless_by_exception()` and `y.it_.valueless_by_exception()` are each `false`.

44 *Effects*: Equivalent to:

```
std::visit([&](const auto& it1, const auto& it2) {
             if constexpr (is_same_v<decltype(it1), decltype(it2)>) {
               ranges::iter_swap(it1, it2);
             } else {
               ranges::swap(*x, *y);
             }
           },
           x.it_, y.it_);
```

45 *Remarks*: The exception specification is equivalent to

```
(noexcept(ranges::swap(*x, *y)) && ... && noexcept(ranges::iter_swap(its, its)))
```

where `its` is a pack of lvalues of type `const iterator_t<maybe-const<Const, Views>>` respectively.

The expression in the *requires-clause* is equivalent to

```
swappable_with<iter_reference_t<iterator>, iter_reference_t<iterator>> &&
(... && indirectly_swappable<iterator_t<maybe-const<Const, Views>>>)
```

25.7.19 Counted view [range.counted]

1 A counted view presents a view of the elements of the counted range (24.3.1) `i` + [`0`, `n`) for an iterator `i` and non-negative integer `n`.

2 The name `views::counted` denotes a customization point object (16.3.3.3.5). Let `E` and `F` be expressions, let `T` be `decay_t<decltype((E))>`, and let `D` be `iter_difference_t<T>`. If `decltype((F))` does not model `convertible_to<D>`, `views::counted(E, F)` is ill-formed.

[*Note 1*: This case can result in substitution failure when `views::counted(E, F)` appears in the immediate context of a template instantiation. — *end note*]

Otherwise, `views::counted(E, F)` is expression-equivalent to:

(2.1) — If `T` models `contiguous_iterator`, then `span(to_address(E), static_cast<size_t>(static_cast<D>(F)))`.

(2.2) — Otherwise, if `T` models `random_access_iterator`, then `subrange(E, E + static_cast<D>(F))`, except that `E` is evaluated only once.

(2.3) — Otherwise, `subrange(counted_iterator(E, F), default_sentinel)`.

25.7.20 Common view [range.common]

25.7.20.1 Overview [range.common.overview]

1 `common_view` takes a view which has different types for its iterator and sentinel and turns it into a view of the same elements with an iterator and sentinel of the same type.

2 [*Note 1*: `common_view` is useful for calling legacy algorithms that expect a range's iterator and sentinel types to be the same. — *end note*]

3 The name `views::common` denotes a range adaptor object (25.7.2). Given a subexpression `E`, the expression `views::common(E)` is expression-equivalent to:

(3.1) — `views::all(E)`, if `decltype((E))` models `common_range` and `views::all(E)` is a well-formed expression.

(3.2) — Otherwise, `common_view{E}`.

4 [*Example 1*:

```
// Legacy algorithm:
template<class ForwardIterator>
size_t count(ForwardIterator first, ForwardIterator last);

template<forward_range R>
void my_algo(R&& r) {
  auto&& common = views::common(r);
  auto cnt = count(common.begin(), common.end());
  // ...
}
```

— *end example*]

25.7.20.2 Class template `common_view` [range.common.view]

```
namespace std::ranges {
  template<view V>
    requires (!common_range<V> && copyable<iterator_t<V>>)

    }
    constexpr auto reserve_hint() const requires approximately_sized_range<const V> {
      return ranges::reserve_hint(base_);
    }
  };

  template<class R>
    common_view(R&&) -> common_view<views::all_t<R>>;
}
```

```
constexpr explicit common_view(V base);
```

1 *Effects*: Initializes *base_* with `std::move(base)`.

25.7.21 Reverse view [range.reverse]

25.7.21.1 Overview [range.reverse.overview]

1 `reverse_view` takes a bidirectional view and produces another view that iterates the same elements in reverse order.

2 The name `views::reverse` denotes a range adaptor object (25.7.2). Given a subexpression `E`, the expression `views::reverse(E)` is expression-equivalent to:

(2.1) — If the type of `E` is a (possibly cv-qualified) specialization of `reverse_view`, then `E.base()`.

(2.2) — Otherwise, if `E` is a specialization of `optional` and `E` models `view`, then *`decay-copy`*`(E)`.

(2.3) — Otherwise, if the type of `E` is *cv* `subrange<reverse_iterator<I>, reverse_iterator<I>, K>` for some iterator type `I` and value `K` of type `subrange_kind`,

(2.3.1) — if `K` is `subrange_kind::sized`, then `subrange<I, I, K>(E.end().base(), E.begin().base(), E.size())`;

(2.3.2) — otherwise, `subrange<I, I, K>(E.end().base(), E.begin().base())`.

However, in either case `E` is evaluated only once.

(2.4) — Otherwise, `reverse_view{E}`.

3 [*Example 1*:

```
vector<int> is {0,1,2,3,4};
for (int i : is | views::reverse)
  cout << i << ' '; // prints 4 3 2 1 0
```

— *end example*]

25.7.21.2 Class template `reverse_view` [range.reverse.view]

```
namespace std::ranges {
  template<view V>
    requires bidirectional_range<V>
  class reverse_view : public view_interface<reverse_view<V>> {
  private:
    V base_ = V();  // exposition only

  public:
    reverse_view() requires default_initializable<V> = default;
```

```
    constexpr explicit reverse_view(V r);

    constexpr V base() const & requires copy_constructible<V> { return base_; }
    constexpr V base() && { return std::move(base_); }

    constexpr reverse_iterator<iterator_t<V>> begin();
    constexpr reverse_iterator<iterator_t<V>> begin() requires common_range<V>;
    constexpr auto begin() const requires common_range<const V>;

    constexpr reverse_iterator<iterator_t<V>> end();
    constexpr auto end() const requires common_range<const V>;

    constexpr auto size() requires sized_range<V> {
      return ranges::size(base_);
    }

    constexpr auto size() const requires sized_range<const V> {
      return ranges::size(base_);
    }

    constexpr auto reserve_hint() requires approximately_sized_range<V> {
      return ranges::reserve_hint(base_);
    }
    constexpr auto reserve_hint() const requires approximately_sized_range<const V> {
      return ranges::reserve_hint(base_);
    }
  };

  template<class R>
    reverse_view(R&&) -> reverse_view<views::all_t<R>>;
}
```

```
constexpr explicit reverse_view(V base);
```

1 *Effects*: Initializes `base_` with `std::move(base)`.

```
constexpr reverse_iterator<iterator_t<V>> begin();
```

2 *Returns*:

```
make_reverse_iterator(ranges::next(ranges::begin(base_), ranges::end(base_)))
```

3 *Remarks*: In order to provide the amortized constant time complexity required by the `range` concept, this function caches the result within the `reverse_view` for use on subsequent calls.

```
constexpr reverse_iterator<iterator_t<V>> begin() requires common_range<V>;
constexpr auto begin() const requires common_range<const V>;
```

4 *Effects*: Equivalent to: `return make_reverse_iterator(ranges::end(base_));`

```
constexpr reverse_iterator<iterator_t<V>> end();
constexpr auto end() const requires common_range<const V>;
```

5 *Effects*: Equivalent to: `return make_reverse_iterator(ranges::begin(base_));`

25.7.22 As const view [range.as.const]

25.7.22.1 Overview [range.as.const.overview]

1 `as_const_view` presents a view of an underlying sequence as constant. That is, the elements of an `as_const_view` cannot be modified.

2 The name `views::as_const` denotes a range adaptor object (25.7.2). Let `E` be an expression, let `T` be `decltype((E))`, and let `U` be `remove_cvref_t<T>`. The expression `views::as_const(E)` is expression-equivalent to:

(2.1) — If `views::all_t<T>` models `constant_range`, then `views::all(E)`.

(2.2) — Otherwise, if `U` denotes `empty_view<X>` for some type `X`, then `auto(views::empty<const X>)`.

(2.3) — Otherwise, if `U` denotes `optional<X&>` for some type `X`, then `optional<const X&>(E)`.

(2.4) — Otherwise, if `U` denotes `span<X, Extent>` for some type `X` and some extent `Extent`, then `span<const X, Extent>(E)`.

(2.5) — Otherwise, if `U` denotes `ref_view<X>` for some type `X` and `const X` models `constant_range`, then `ref_view(static_cast<const X&>(E.base()))`.

(2.6) — Otherwise, if `E` is an lvalue, `const U` models `constant_range`, and `U` does not model `view`, then `ref_view(static_cast<const U&>(E))`.

(2.7) — Otherwise, `as_const_view(E)`.

3 [*Example 1*:

```
template<constant_range R>
void cant_touch_this(R&&);

vector<char> hammer = {'m', 'c'};
span<char> beat = hammer;
cant_touch_this(views::as_const(beat));          // will not modify the elements of hammer
```

— *end example*]

25.7.22.2 Class template `as_const_view` [range.as.const.view]

```
namespace std::ranges {
  template<view V>
    requires input_range<V>
  class as_const_view : public view_interface<as_const_view<V>> {
    V base_ = V();      // exposition only

  public:
    as_const_view() requires default_initializable<V> = default;
    constexpr explicit as_const_view(V base);

    constexpr V base() const & requires copy_constructible<V> { return base_; }
    constexpr V base() && { return std::move(base_); }

    constexpr auto begin() requires (!simple-view<V>) { return ranges::cbegin(base_); }
    constexpr auto begin() const requires range<const V> { return ranges::cbegin(base_); }

    constexpr auto end() requires (!simple-view<V>) { return ranges::cend(base_); }
    constexpr auto end() const requires range<const V> { return ranges::cend(base_); }

    constexpr auto size() requires sized_range<V> { return ranges::size(base_); }
    constexpr auto size() const requires sized_range<const V> { return ranges::size(base_); }

    constexpr auto reserve_hint() requires approximately_sized_range<V>
    { return ranges::reserve_hint(base_); }
    constexpr auto reserve_hint() const requires approximately_sized_range<const V>
    { return ranges::reserve_hint(base_); }
  };

  template<class R>
    as_const_view(R&&) -> as_const_view<views::all_t<R>>;
}
```

```
constexpr explicit as_const_view(V base);
```

1 *Effects*: Initializes `base_` with `std::move(base)`.

25.7.23 Elements view [range.elements]

25.7.23.1 Overview [range.elements.overview]

1 `elements_view` takes a view of tuple-like values and a `size_t`, and produces a view with a value-type of the N^{th} element of the adapted view's value-type.

2 The name `views::elements<N>` denotes a range adaptor object (25.7.2). Given a subexpression `E` and constant expression `N`, the expression `views::elements<N>(E)` is expression-equivalent to `elements_view<views::all_t<decltype((E))>, N>{E}`.

[*Example 1*:

```
auto historical_figures = map{
  pair{"Lovelace"sv, 1815},
  {"Turing"sv, 1912},
  {"Babbage"sv, 1791},
  {"Hamilton"sv, 1936}
};

auto names = historical_figures | views::elements<0>;
for (auto&& name : names) {
  cout << name << ' ';          // prints Babbage Hamilton Lovelace Turing
}

auto birth_years = historical_figures | views::elements<1>;
for (auto&& born : birth_years) {
  cout << born << ' ';          // prints 1791 1936 1815 1912
}
```

— *end example*]

3 `keys_view` is an alias for `elements_view<R, 0>`, and is useful for extracting keys from associative containers.

[*Example 2*:

```
auto names = historical_figures | views::keys;
for (auto&& name : names) {
  cout << name << ' ';          // prints Babbage Hamilton Lovelace Turing
}
```

— *end example*]

4 `values_view` is an alias for `elements_view<R, 1>`, and is useful for extracting values from associative containers.

[*Example 3*:

```
auto is_even = [](const auto x) { return x % 2 == 0; };
cout << ranges::count_if(historical_figures | views::values, is_even);  // prints 2
```

— *end example*]

25.7.23.2 Class template `elements_view` [range.elements.view]

```
namespace std::ranges {
  template<class T, size_t N>
  concept has-tuple-element =                    // exposition only
    tuple-like<T> && N < tuple_size_v<T> &&

  };
}
```

[1] The member *typedef-name* `iterator_concept` is defined as follows:

(1.1) — If *`Base`* models `random_access_range`, then `iterator_concept` denotes `random_access_iterator_tag`.

(1.2) — Otherwise, if *`Base`* models `bidirectional_range`, then `iterator_concept` denotes `bidirectional_iterator_tag`.

(1.3) — Otherwise, if *`Base`* models `forward_range`, then `iterator_concept` denotes `forward_iterator_tag`.

(1.4) — Otherwise, `iterator_concept` denotes `input_iterator_tag`.

[2] The member *typedef-name* `iterator_category` is declared if and only if *`Base`* models `forward_range`. In that case, `iterator_category` is defined as follows: Let `C` denote the type `iterator_traits<iterator_t<Base>>::iterator_category`.

(2.1) — If `std::get<N>(*current_)` is an rvalue, `iterator_category` denotes `input_iterator_tag`.

(2.2) — Otherwise, if `C` models `derived_from<random_access_iterator_tag>`, `iterator_category` denotes `random_access_iterator_tag`.

(2.3) — Otherwise, `iterator_category` denotes `C`.

```
static constexpr decltype(auto) get-element(const iterator_t<Base>& i);
```

3 *Effects*: Equivalent to:

```
if constexpr (is_reference_v<range_reference_t<Base>>) {
  return std::get<N>(*i);
} else {
  using E = remove_cv_t<tuple_element_t<N, range_reference_t<Base>>>;
  return static_cast<E>(std::get<N>(*i));
}
```

```
constexpr explicit iterator(iterator_t<Base> current);
```

4 *Effects*: Initializes *current_* with `std::move(current)`.

```
constexpr iterator(iterator<!Const> i)
  requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;
```

5 *Effects*: Initializes *current_* with `std::move(i.current_)`.

```
constexpr const iterator_t<Base>& base() const & noexcept;
```

6 *Effects*: Equivalent to: `return current_;`

```
constexpr iterator_t<Base> base() &&;
```

        operator-(const iterator<OtherConst>& x, const sentinel& y);

      template<bool OtherConst>
        requires sized_sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
      friend constexpr range_difference_t<maybe-const<OtherConst, V>>
        operator-(const sentinel& x, const iterator<OtherConst>& y);
    };
  }
```

```
constexpr explicit sentinel(sentinel_t<Base> end);
```

1 *Effects*: Initializes *end_* with end.

```
constexpr sentinel(sentinel<!Const> other)
  requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;
```

2 *Effects*: Initializes *end_* with std::move(other.*end_*).

```
constexpr sentinel_t<Base> base() const;
```

3 *Effects*: Equivalent to: return *end_*;

```
template<bool OtherConst>
  requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);
```

4 *Effects*: Equivalent to: return x.*current_* == y.*end_*;

```
template<bool OtherConst>
  requires sized_sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
friend constexpr range_difference_t<maybe-const<OtherConst, V>>
  operator-(const iterator<OtherConst>& x, const sentinel& y);
```

5 *Effects*: Equivalent to: return x.*current_* - y.*end_*;

```
template<bool OtherConst>
  requires sized_sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
friend constexpr range_difference_t<maybe-const<OtherConst, V>>
  operator-(const sentinel& x, const iterator<OtherConst>& y);
```

6 *Effects*: Equivalent to: return x.*end_* - y.*current_*;

25.7.24 Enumerate view [range.enumerate]

25.7.24.1 Overview [range.enumerate.overview]

1 enumerate_view is a view whose elements represent both the position and value from a sequence of elements.

2 The name views::enumerate denotes a range adaptor object (25.7.2). Given a subexpression E, the expression views::enumerate(E) is expression-equivalent to enumerate_view<views::all_t<decltype((E))>>(E).

[*Example 1*:

```
vector<int> vec{ 1, 2, 3 };
for (auto [index, value] : views::enumerate(vec))
  cout << index << ":" << value << ' ';          // prints 0:1 1:2 2:3
```

— *end example*]

25.7.24.2 Class template `enumerate_view` [range.enumerate.view]

```
namespace std::ranges {
  template<view V>
    requires range-with-movable-references<V>
  class enumerate_view : public view_interface<enumerate_view<V>> {
    V base_ = V();                                      // exposition only

    // 25.7.24.3, class template enumerate_view::iterator
    template<bool Const>
      class iterator;                                   // exposition only

    // 25.7.24.4, class template enumerate_view::sentinel

```

6 *Effects*: Equivalent to: `return x.end_ - y.current_;`

25.7.25 Zip view [range.zip]

25.7.25.1 Overview [range.zip.overview]

1 `zip_view` takes any number of views and produces a view of tuples of references to the corresponding elements of the constituent views.

2 The name `views::zip` denotes a customization point object (16.3.3.3.5). Given a pack of subexpressions `Es...`, the expression `views::zip(Es...)` is expression-equivalent to

(2.1) — `auto(views::empty<tuple<>>)` if `Es` is an empty pack,

(2.2) — otherwise, `zip_view<views::all_t<decltype((Es))>...>(Es...)`.

[*Example 1*:

```
vector v = {1, 2};
list l = {'a', 'b', 'c'};

auto z = views::zip(v, l);
range_reference_t<decltype(z)> f = z.front();   // f is a tuple<int&, char&>
                                                // that refers to the first element of v and l

for (auto&& [x, y] : z) {
  cout << '(' << x << ", " << y << ") ";        // prints (1, a) (2, b)
}
```

— *end example*]

25.7.25.2 Class template `zip_view` [range.zip.view]

```
namespace std::ranges {
  template<class... Rs>
  concept zip-is-common =                                  // exposition only
    (sizeof...(Rs) == 1 && (common_range<Rs> && ...)) ||
    (!(bidirectional_range<Rs> && ...) && (common_range<Rs> && ...)) ||
    ((random_access_range<Rs> && ...) && (sized_range<Rs> && ...));

  template<input_range... Views>
    requires (view<Views> && ...) && (sizeof...(Views) > 0)
  class zip_view : public view_interface<zip_view<Views...>> {
    tuple<Views...> views_;                // exposition only

    // 25.7.25.3, class template zip_view::iterator
    template<bool> class iterator;         // exposition only

    // 25.7.25.4, class template zip_view::sentinel
    template<bool> class sentinel;         // exposition only

  public:
    zip_view() = default;
    constexpr explicit zip_view(Views... views);

    constexpr auto begin() requires (!(simple-view<Views> && ...)) {
      return iterator<false>(tuple-transform(ranges::begin, views_));
    }
    constexpr auto begin() const requires (range<const Views> && ...) {
      return iterator<true>(tuple-transform(ranges::begin, views_));
    }

    constexpr auto end() requires (!(simple-view<Views> && ...)) {
      if constexpr (!zip-is-common<Views...>) {
        return sentinel<false>(tuple-transform(ranges::end, views_));
      } else if constexpr ((random_access_range<Views> && ...)) {
        return begin() + iter_difference_t<iterator<false>>(size());
      } else {
        return iterator<false>(tuple-transform(ranges::end, views_));
      }
    }

    constexpr auto end() const requires (range<const Views> && ...) {
      if constexpr (!zip-is-common<const Views...>) {
        return sentinel<true>(tuple-transform(ranges::end, views_));
      } else if constexpr ((random_access_range<const Views> && ...)) {
        return begin() + iter_difference_t<iterator<true>>(size());
      } else {
        return iterator<true>(tuple-transform(ranges::end, views_));
      }
    }

    constexpr auto size() requires (sized_range<Views> && ...);
    constexpr auto size() const requires (sized_range<const Views> && ...);
  };

  template<class... Rs>
    zip_view(Rs&&...) -> zip_view<views::all_t<Rs>...>;
}
```

[1] Two `zip_view` objects have the same underlying sequence if and only if the corresponding elements of *views_* are equal (18.2) and have the same underlying sequence.

[*Note 1*: In particular, comparison of iterators obtained from `zip_view` objects that do not have the same underlying sequence is not required to produce meaningful results (24.3.4.11). — *end note*]

```
constexpr explicit zip_view(Views... views);
```

2 *Effects*: Initializes *views_* with `std::move(views)...`.

```
constexpr auto size() requires (sized_range<Views> && ...);
constexpr auto size() const requires (sized_range<const Views> && ...);
```

3 *Effects*: Equivalent to:

```
return apply([](auto... sizes) {
  using CT = make-unsigned-like-t<common_type_t<decltype(sizes)...>>;
  return ranges::min({CT(sizes)...});
}, tuple-transform(ranges::size, views_));
```

25.7.25.3 Class template zip_view::*iterator* [range.zip.iterator]

```
namespace std::ranges {
  template<input_range... Views>
    requires (view<Views> && ...) && (sizeof...(Views) > 0)
  template<bool Const>
  class zip_view<Views...>::iterator {
    tuple<iterator_t<maybe-const<Const, Views>>...> current_;       // exposition only
    constexpr explicit iterator(tuple<iterator_t<maybe-const<Const, Views>>...>);
                                                                    // exposition only
  public:
    using iterator_category = input_iterator_tag;                   // not always present
    using iterator_concept  = see below;
    using value_type = tuple<range_value_t<maybe-const<Const, Views>>...>;
    using difference_type = common_type_t<range_difference_t<maybe-const<Const, Views>>...>;

    iterator() = default;
    constexpr iterator(iterator<!Const> i)
      requires Const && (convertible_to<iterator_t<Views>, iterator_t<const Views>> && ...);

    constexpr auto operator*() const;
    constexpr iterator& operator++();
    constexpr void operator++(int);
    constexpr iterator operator++(int) requires all-forward<Const, Views...>;

    constexpr iterator& operator--() requires all-bidirectional<Const, Views...>;
    constexpr iterator operator--(int) requires all-bidirectional<Const, Views...>;

    constexpr iterator& operator+=(difference_type x)
      requires all-random-access<Const, Views...>;
    constexpr iterator& operator-=(difference_type x)
      requires all-random-access<Const, Views...>;

    constexpr auto operator[](difference_type n) const
      requires all-random-access<Const, Views...>;

    friend constexpr bool operator==(const iterator& x, const iterator& y)
      requires (equality_comparable<iterator_t<maybe-const<Const, Views>>> && ...);

    friend constexpr auto operator<=>(const iterator& x, const iterator& y)
      requires all-random-access<Const, Views...>;

    friend constexpr iterator operator+(const iterator& i, difference_type n)
      requires all-random-access<Const, Views...>;
    friend constexpr iterator operator+(difference_type n, const iterator& i)
      requires all-random-access<Const, Views...>;
    friend constexpr iterator operator-(const iterator& i, difference_type n)
      requires all-random-access<Const, Views...>;
    friend constexpr difference_type operator-(const iterator& x, const iterator& y)
      requires (sized_sentinel_for<iterator_t<maybe-const<Const, Views>>,
                                   iterator_t<maybe-const<Const, Views>>> && ...);

    friend constexpr auto iter_move(const iterator& i) noexcept(see below);
```

```
    friend constexpr void iter_swap(const iterator& l, const iterator& r) noexcept(see below)
      requires (indirectly_swappable<iterator_t<maybe-const<Const, Views>>> && ...);
  };
}
```

1 *iterator*::iterator_concept is defined as follows:

(1.1) — If *all-random-access*<Const, Views...> is modeled, then iterator_concept denotes random_access_iterator_tag.

(1.2) — Otherwise, if *all-bidirectional*<Const, Views...> is modeled, then iterator_concept denotes bidirectional_iterator_tag.

(1.3) — Otherwise, if *all-forward*<Const, Views...> is modeled, then iterator_concept denotes forward_iterator_tag.

(1.4) — Otherwise, iterator_concept denotes input_iterator_tag.

2 *iterator*::iterator_category is present if and only if *all-forward*<Const, Views...> is modeled.

3 If the invocation of any non-const member function of *iterator* exits via an exception, the iterator acquires a singular value.

```
constexpr explicit iterator(tuple<iterator_t<maybe-const<Const, Views>>...> current);
```

4 *Effects*: Initializes *current_* with std::move(current).

```
constexpr iterator(iterator<!Const> i)
  requires Const && (convertible_to<iterator_t<Views>, iterator_t<const Views>> && ...);
```

5 *Effects*: Initializes *current_* with std::move(i.*current_*).

```
constexpr auto operator*() const;
```

6 *Effects*: Equivalent to:

```
return tuple-transform([](auto& i) -> decltype(auto) { return *i; }, current_);
```

```
constexpr iterator& operator++();
```

7 *Effects*: Equivalent to:

```
tuple-for-each([](auto& i) { ++i; }, current_);
return *this;
```

```
constexpr void operator++(int);
```

8 *Effects*: Equivalent to ++*this.

```
constexpr iterator operator++(int) requires all-forward<Const, Views...>;
```

9 *Effects*: Equivalent to:

```
auto tmp = *this;
++*this;
return tmp;
```

```
constexpr iterator& operator--() requires all-bidirectional<Const, Views...>;
```

10 *Effects*: Equivalent to:

```
tuple-for-each([](auto& i) { --i; }, current_);
return *this;
```

```
constexpr iterator operator--(int) requires all-bidirectional<Const, Views...>;
```

11 *Effects*: Equivalent to:

```
auto tmp = *this;
--*this;
return tmp;
```

```
constexpr iterator& operator+=(difference_type x)
  requires all-random-access<Const, Views...>;
```

12 *Effects*: Equivalent to:

```
    tuple-for-each([&]<class I>(I& i) { i += iter_difference_t<I>(x); }, current_);
    return *this;
```

```
constexpr iterator& operator-=(difference_type x)
  requires all-random-access<Const, Views...>;
```

13 *Effects*: Equivalent to:

```
    tuple-for-each([&]<class I>(I& i) { i -= iter_difference_t<I>(x); }, current_);
    return *this;
```

```
constexpr auto operator[](difference_type n) const
  requires all-random-access<Const, Views...>;
```

14 *Effects*: Equivalent to:

```
    return tuple-transform([&]<class I>(I& i) -> decltype(auto) {
      return i[iter_difference_t<I>(n)];
    }, current_);
```

```
friend constexpr bool operator==(const iterator& x, const iterator& y)
  requires (equality_comparable<iterator_t<maybe-const<Const, Views>>> && ...);
```

15 *Returns*:

(15.1) — `x.current_ == y.current_` if `all-bidirectional<Const, Views...>` is `true`.

(15.2) — Otherwise, `true` if there exists an integer $0 \leq i <$ `sizeof...(Views)` such that `bool(std::get<`i`>(x.current_) == std::get<`i`>(y.current_))` is `true`.

[*Note 1*: This allows `zip_view` to model `common_range` when all constituent views model `common_range`. — *end note*]

(15.3) — Otherwise, `false`.

```
friend constexpr auto operator<=>(const iterator& x, const iterator& y)
  requires all-random-access<Const, Views...>;
```

16 *Returns*: `x.current_ <=> y.current_`.

```
friend constexpr iterator operator+(const iterator& i, difference_type n)
  requires all-random-access<Const, Views...>;
friend constexpr iterator operator+(difference_type n, const iterator& i)
  requires all-random-access<Const, Views...>;
```

17 *Effects*: Equivalent to:

```
    auto r = i;
    r += n;
    return r;
```

```
friend constexpr iterator operator-(const iterator& i, difference_type n)
  requires all-random-access<Const, Views...>;
```

18 *Effects*: Equivalent to:

```
    auto r = i;
    r -= n;
    return r;
```

```
friend constexpr difference_type operator-(const iterator& x, const iterator& y)
  requires (sized_sentinel_for<iterator_t<maybe-const<Const, Views>>,
                               iterator_t<maybe-const<Const, Views>>> && ...);
```

19 Let *DIST*(*i*) be `difference_type(std::get<`*i*`>(x.current_) - std::get<`*i*`>(y.current_))`.

20 *Returns*: The value with the smallest absolute value among *DIST*(*n*) for all integers $0 \leq n <$ `sizeof...(Views)`.

```
friend constexpr auto iter_move(const iterator& i) noexcept(see below);
```

21 *Effects*: Equivalent to:

```
    return tuple-transform(ranges::iter_move, i.current_);
```

22 *Remarks*: The exception specification is equivalent to:

```
      (noexcept(ranges::iter_move(declval<const iterator_t<maybe-const<Const,
                                                          Views>>&>())) && ...) &&
      (is_nothrow_move_constructible_v<range_rvalue_reference_t<maybe-const<Const,
                                                                Views>>> && ...)

friend constexpr void iter_swap(const iterator& l, const iterator& r) noexcept(see below)
  requires (indirectly_swappable<iterator_t<maybe-const<Const, Views>>> && ...);
```

23 *Effects*: For every integer $0 \leq i <$ `sizeof...(Views)`, performs:

```
ranges::iter_swap(std::get<i>(l.current_), std::get<i>(r.current_))
```

24 *Remarks*: The exception specification is equivalent to the logical AND of the following expressions:

```
noexcept(ranges::iter_swap(std::get<i>(l.current_), std::get<i>(r.current_)))
```

for every integer $0 \leq i <$ `sizeof...(Views)`.
